INDEX TO VOLUME C

July 1 to December 31, 1915

Explanatory Note

Illustrated articles are denoted by an asterisk (*), book notices by a dagger (†).

The intention is to make this index comprehensive, embodying a liberal selection of news notes together with more important articles, but at the same time **very concise.** Much pains are taken to bring together matter relating to the same subject so that when a reader looks up an article he will be cited to related data. Under these conditions some further explanation of the method will be useful as an aid in finding leading articles quickly. Series of simple page numbers following names of mines or companies usually refer to news notes and other lesser matters. Descriptive articles are appended under titles (often abbreviated) begining with dashes. When the minor references are numerous, as in the case of "Anaconda," they are sometimes separately designated as "notes." The unspecified entries may, however, be important; occasionally, for instance, an editorial or other article is entitled simply by a proper name. Thus, the entries relating to the "Mexican situation" begin with a number of major ones, not distinguished in detail, followed by others which are so distinguished and by a group of notes at the end. (Additional notes on Mexico might, of course, be found elsewhere under the names of particular mines, etc.) With a major entry or series of entries may be placed several minor ones relating to the same subject in order that its history may be followed. This plan is employed the more readily when the important articles begin the series. The asterisks denoting illustrated articles assist in finding them and if the author's name be known it is the simplest means of reference. Productions are indexed under names of metals and countries or states, in important cases under both. The mere juxtaposition of a mineral and geographical name usually signifies an output but may cover other statistical or news matter.

Following is a list of the pages included in the several numbers of the volume, by date:

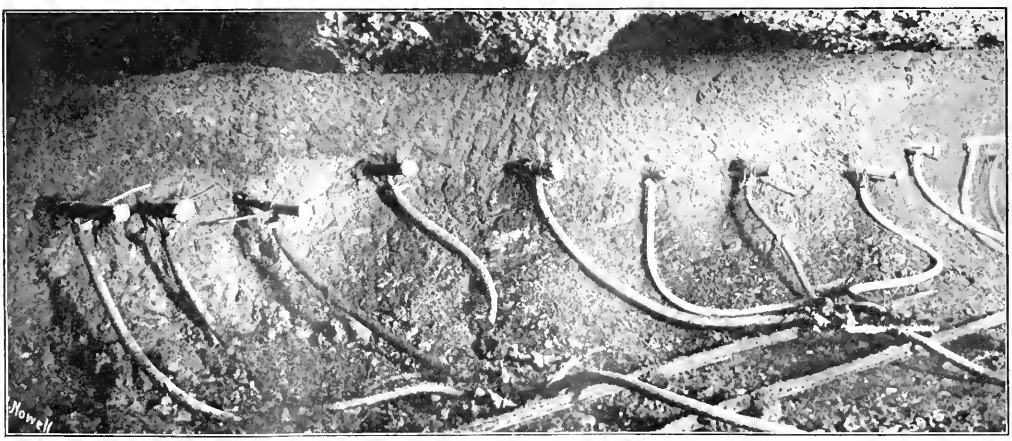
Thawing Methods at Fairbanks

By Hubert I. Ellis*

SYNOPSIS—Thawing the frozen paystreak is one of the most important details of mining at Fairbanks. Wood fires were formerly used, but had obvious disadvantages. The efficiency of steampipe methods was accidentally discovered in principle, and has been developed into the only feasible procedure. Full description of principles and practice is given.

After the "opening up," or development, of a typical Fairbanks placer mine, the next step, leaving out of consideration for the present the washing plant, is putting in the first "thaw." Since thawing the permanently frozen material of the paystreak is one of the most important and expensive items entering into the cost of mining—averaging about 20% of the total—the history and development of the steam point will be briefly discussed.



A Battery of Steam Points at Work in the Gravel

Thawing with Wood Fires

Before the discovery of gold at Dawson there had been considerable mining in the great region tributary to the Yukon, notably at Circle, Kewkuk, and on the Stewart River. Where the heat of the sun was not available for thawing, wood fires were used. The slow, easy-going methods of the old timers did not meet with the approval of the eager Dawson stampeders, however, and they cast about for some more efficient scheme for removing the frost from the gravel.

The first attempt to thaw underground, otherwise than with wood fires, seems to have been made on Bonanza Creek in 1898. Pipe boilers of 10-hp. capacity were used to generate steam for siphons and injectors, by means of which warm water was played against the frozen face. The larger rocks were picked loose as fast as they thawed from the matrix and were thrown back to serve as support for the roof. Subsequently pipe boilers of 20 and 25 hp. were introduced, and pulsometer pumps were used to force the water against the face.

This method was applied especially to bench deposits opened by adit, and was used to some extent during winter. The gravel was thawed at night and the rocks removed, and during the day the fine gravel was shoveled into 6-in. sluice boxes supplied with water by the pump used at night for thawing. The tailings were discharged into a box outside the mine, from which they were shoveled into wheelbarrows and wheeled to the edge of the dump. Water, being a scarce article on the benches both in winter and in summer, was used over and over. In driving tunnels with the pulsometer pump an advance of 8 to 10 ft. per day was easily made. The pump as a means of thawing did not give satisfaction, however, chiefly on account of the unavoidable thawing and sloughing of the roof.

Discovery of the Steam-Point Principle

The principle of the steam point was discovered by accident. An engineer noted that the exhaust of the engine he was using had thawed a hole in the surface muck with

*4352 Ninth Ave., N. E., Seattle, Wash.

which it came in contact. This aroused his curiosity and led to casual experiments, which proved that live steam was an effective agency for thawing the muck. The big problem, however, was to thaw the gravel, since the muck handled was comparatively insignificant in amount and could be removed by picking. The inference was obvious that steam, if it would thaw muck, which is more than 50% ice, would likewise thaw gravel, in which the proportion of ice is much less. But here arose another difficulty—that of getting the steam to the interior of the deposit of gravel to be thawed. Since ordinary pipe could not be driven into such resistant material, the first method that suggested itself was to drill the holes with ordinary hand steel and insert the steampipe afterward; but the prohibitive cost of labor prevented serious consideration of this possibility. Then it was remembered that, although frozen gravel was as resistant as concrete, a pick or crowbar could be driven readily into the gravel once it was thawed, and the idea of using hollow drill steel carrying live steam followed as a logical consequence. No drill steel of this kind being at hand, there was substituted the ingenious but ineffective makeshift shown in Fig. 1. This

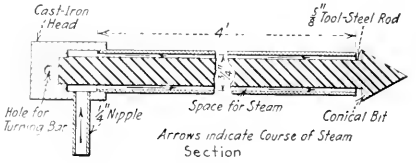


FIG.1

THE FIRST STEAM POINT

consisted of a 4-ft. iron pipe with a ⅝-in. tool-steel rod passing through the center and ending in a conical bit larger than the outside diameter of the pipe. The point had a cast-iron head with a ¼-in. nipple tapped in to admit steam to the annular space between the pipe and the rod. The conical bit cleared away the ground in front of the pipe, much as a churn-drill clears the way for the

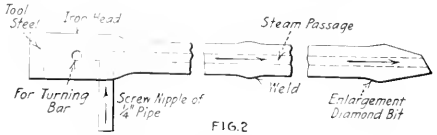

FIG.2

TWO GUN BARRELS WELDED TO MAKE A STEAM POINT

casing, except that the gravel was pushed to the side instead of being removed. This point was driven by means of a wooden mallet, and although fairly satisfactory at that time for soft ground, it could not be used successfully where driving was hard. It added further proof of the value of the principle, however, and served to pave the way for an improved tool.

The next step in the development of the steam point consisted of welding together two gun barrels, welding on an iron head and a tool-steel bit, and tapping in a ¼-in. pipe for the admission of steam (Fig. 2). This form of steam connection proved unsatisfactory under the heavy hammering to which the point was subjected, and what was known as the boiler-rivet nipple was substituted, as shown in Fig. 3. The rivet was placed and caulked to prevent leakage of steam and the steam passage was drilled out afterward. In a later design the rivet was welded to the head of the point, but this was soon replaced by the modern nipple point, which is described in what follows.

The gun-barrel point having proved, in an experimental way, the value of the principle underlying the design, hydraulic pipe (XXXX) was obtained for the barrel of the point, a tool-steel bit and a rolled-steel head being welded on, as shown in Fig. 3. Hollow drill steel was later substituted for the hydraulic pipe, and it became unnecessary to weld on a tool-steel driving point. Fig. 4

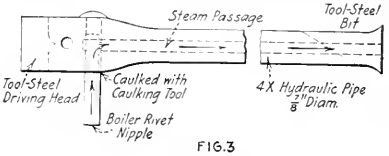

FIG.3

THE THIRD STEAM POINT

Hydraulic pipe with tool-steel bit

shows the entire modern nipple point and Fig. 6 illustrates the details of the head and nipple.

DESIGN OF STEAM CONNECTIONS

The steam connection has been the source of more trouble than all the rest of the point. Many connections have been invented and used to a greater or less extent in practice; some operators prefer one, some another. The nippleless-socket point with drop-forged connections, one type of which is shown at A, Fig. 5, has found a wide market in a great variety of designs. For all-around purposes, however, the nipple point has much to recommend its use. The chief objection to the yoke and other socket-type points, aside from the cost, is that the nuts constantly work loose under the hammering in driving and require frequent tightening. This takes but a moment's time, but

FIG.4

MODERN STEAM POINT

Hollow drill-steel barrel, cold-rolled steel head and solid-welded nipple

the threads on the yoke gradually become worn and the yoke itself frequently crystallizes and breaks. Since it is not convenient for the pointman to put on a new yoke underground, owing to the loss of time involved and the unfavorable conditions for such work, the point must be disconnected and withdrawn and another inserted. With the nipple point the only part to work loose is the clamp, and this is fastened to the point head by baling wire to prevent its coming loose suddenly and scalding the operator with hot steam. In my experience the clamp requires less attention than the nuts on the yoke of the nippleless point, and the nipple point never has to be sent to the surface on account of poor connections. The hose, further, can be disconnected from the point as easily as from the crosshead, which is not the case with the other points, and which may be important where "sweaters" are used, as described later. In the matter of cost, too, the nipple point has a great advantage, since it costs only $10 or $12, against $20 for the corresponding sizes of the others. The projecting nipple is subject to being broken by a misdirected blow from the hammer; but this is an accident that is too rare to be worth mentioning.

The points used at Dawson before the Fairbanks operators developed a slightly different and more efficient

practice were 5 and 6 ft. long. Those used at Fairbanks are 8, 10, 12, 16 and 20 ft. long. The longer the point, the heavier must be the steel required to prevent buckling and bending, the more cumbersome becomes the point with its attached hose, and the harder it is to drive. The 8-ft. length is most popular at Fairbanks at present, partly because it is easier to regulate the depth of thaw with short points; but longer points are often used in driving tunnels. In using long points the holes are started with short points, which are withdrawn to permit

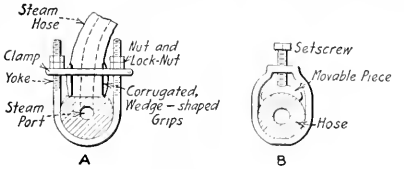

FIG.5

POINT WITHOUT NIPPLE

the insertion of the long ones, and after steam has been turned on for several hours, depending on the character of the gravel, the point is drawn back about half its length to insure a uniform thaw.

DRIVING METHODS AND BITS

Wooden mallets were first used for driving, then the single jack of the quartz miner was adopted, and later double-hand hammers of 7 to 16 lb. weight were used. The heaviest hammers are too hard on the points and are used only where driving is especially hard; the 10-lb. size is most used at present. As a general thing, heavy blows will not send the point "home" any faster than lighter blows at shorter intervals, since it is impossible to drive the point faster than the gravel thaws ahead of it; as noted in the foregoing, however, this rule regarding heavy blows does not hold for exceptionally tight ground.

Three types of bits are used on the point—the "diamond," or square bit (Fig. 2), the chisel bit, such as is used on ordinary hand steel (Fig. 3), and the four-cornered, or Burleigh, bit. For easy-driving ground it has been found that the rocks are more easily pushed aside, when the surrounding material has been thawed, than drilled through, and the diamond point is preferred. Boulders too large to be pushed aside are often split wide open. When driving is harder and it is necessary actually to drill out much of the gravel the ordinary chisel bit is used, or if this is too hard to turn, as frequently happens, the four-cornered bit is employed. With the growth of the practice of driving each point to its full length before starting another, the diamond-bit, formerly almost exclusively used, is becoming a rarity on many of the creeks.

Up to the present time all driving has been done by hand. Power drills offer an attractive possibility to the operator looking to reduce his working costs, but their use has never been attended with success. In the first place, few of the mines can afford an air compressor, and drills must be run with steam, with the attendant disadvantage of the sloughing of the roof due to exhausting steam into the air. The first attempt was made on King Solomon Hill, at Dawson, with a reciprocating drill. This was a failure, and it was years before the next trial. In 1911 William Burns, of Little Eldorado Creek, Fairbanks district, installed a Chicago compressor and tried the Leyner drills. Failure was due partly to the freezing of the exhaust, no provision having been made to deliver dry air to the drill, and partly to the fact that the drill was not powerful enough to pull back through the gravel that constantly dropped around the point and wedged against the bit. A larger machine might have overcome this difficulty to some extent, but it is improbable that any type of reciprocating drill would give satisfaction. In 1913 and 1914 E. M. Keys, of Chatanika, tried out an Ingersoll-Rand BC-26 hand-hammer drill, steam-driven, with a measure of success, the principal disadvantage that developed being that two men were required to operate it. One of the large drill-manufacturing companies is now working, with every promise of success, on a rig to be handled by one man. This machine will probably be placed on the market during the current year, and it is not unlikely that hand-driving will soon be largely supplanted by machine-driving.

USE OF HOT WATER FOR DRIVING

The use of hot water for driving—steam being turned on after the points are "home"—was formerly a popular practice, and some operators still follow it. Its chief advantage is the absence of steam from "blowing back" while driving, which makes the work easier and more agreeable for the pointman and decreases the sloughing of the roof. Its disadvantages are that the water washes the sediment from the gravel and prevents effective plugging, as will appear later; that the system is very cumbersome, requiring duplication of pipe lines; and that the increased amount of water draining away from the face is an inconvenience, often causing trouble with drains, timbers, and car track. As a whole, driving with water is not to be recommended except under unusual circumstances.

The steam line is carried through the tunnels on the posts of the sets and is laid on the floor 10 ft. or more back from the face when thawing. Care must be exercised to keep it out of water at all times; otherwise there will be a large loss from condensation and sloughing from steam turned into the atmosphere. Steam lines under-

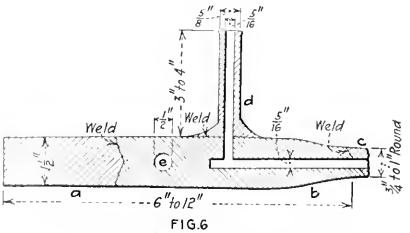

FIG.6

DETAIL OF MODERN NIPPLE POINT

Main part of head is of cold-rolled machine steel, drilled, with tool-steel head to receive blows. Nipple is welded on solid and steam passage drilled afterward

ground are never protected by any insulating material. All joints are smeared with graphite in oil when connected in order that they may be taken apart more easily. Pipe of ¾-in. diameter is most used for the various leads underground.

Fig. 7 shows a crosshead and connections to points and steam line. The point hoses are of Gorham or Goodrich manufacture, ⅝ in. in diameter, and fit over a ⅜-in. nipple on the crosshead, to which they are attached by clamps of the type shown at *B*, Fig. 5. The crosshead is

attached to the line by a ¾-in. hose. Crossheads of fittings one size smaller than those shown are sometimes used, but have no advantage other than decreased weight, and are more likely to be broken by falling rocks. All pipes are rapidly corroded and usually do not last longer than two or three years. Galvanized pipes are never employed, probably because of failure to appreciate their advantages.

Manner of Driving Steam Points

The easiest place to drive a point is neither in gravel nor in bedrock, but right where the two join, except where the bedrock is so badly decomposed as to be a sort of mush when thawed, or where there is a layer of large rocks just above the bedrock. The amount of bedrock taken up depends chiefly on the nature of it. If blocky, gold will be found to a considerable depth, but if soft, gold will not penetrate so far. The top of the bedrock is usually carried 1½ to 2 ft. above the floor. The ease of driving

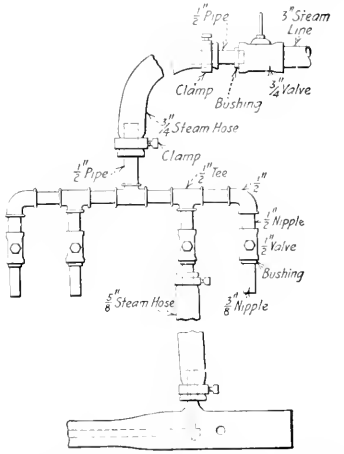

Fig. 7. Crosshead and Connections

Wheels are removed from valve stems to prevent binding by falling rock. The wheel is carried by the foreman or opened with a pair of tweezers

varies greatly with different ground, and even at the same face. At some mines, such as those on Engineer Creek, one man easily thaws the ground for 16 or more shovelers and has time to shovel waste; at the mouth of Dome and Cleary, on the other hand, six men may be required to do the same work. In easy ground two men working separately can accomplish more than two working together; but the usual practice of the district is for pointmen to work in pairs, one striking while the other rotates the point. The men change places every few minutes.

It was formerly the practice to start a number of points, usually the total number required for a single face if the supply was sufficient, and to drive them alternately as far as they would go without resistance. In this way one or two men could drive many points without the heavy hammering sometimes necessary where each point is driven alone, which is easier on the rigging and easier on the pointman. The increased use of "sweaters," with only new points for drilling the holes, has discouraged this practice, however, and it is now usual to drive but one point at a time.

In driving, the point-hose is connected to the crosshead and the point is placed against the face at the proper height. The head is supported on a "horse," Fig. 8, or on a box, or is held across the knee by the assistant, dry gunnysacks being used for protection from the heat. A little steam is turned on and the hammerman strikes the head, gently at first, while the assistant rotates the point back and forth through an angle of 90° to 180°, depending on the type of bit used. At first much steam "blows back" around the point and fills the workings, causing the roof to slough and rendering vision difficult unless the stoped-out area is large. The point is usually so low that the hammerman must stoop to strike, and frequently he must keep his face close to the head of the point in order to see well enough to strike accurately. As the steam escapes into the atmosphere the temperature rises and there is a constant shower of gravel from the roof. Boulders of various sizes, up to a foot or more in diameter, seek with strange fatality the head of the hapless pointman as a place on which to drop. A careful pointman therefore keeps a weather eye on the roof at all times and knocks the larger rocks down before they have a chance to fall on him; but in most ground it is impossible to avoid being struck with distressing frequency. Owing to the

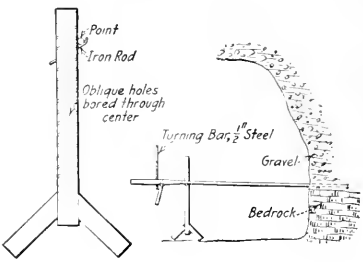

Fig. 8. Horse Sometimes Used in Point Driving, and Its Manner of Application

excessive amount of water vapor the candles flicker dimly and the pointman, fumbling around in the faint light, finds point, pipe, and hose red-hot to the touch. Gloves soon become soaked with water and offer scant protection from the heat. A tool laid to one side and forgotten for a few minutes is buried beyond hope of recovery beneath the falling waste. All in all, the pointman's lot is not particularly attractive, yet there are many who prefer that job to any other in the mine—possibly because the pay is usually a dollar more a day. Lest it be said that the preceding description is overdrawn it may be noted that it takes no account of the low roofs in some mines, where there may be no chance for hours to straighten the kinks from the back, and that the air is sometimes so thick with water vapor that a candle cannot be made to burn; in which case electric lights must be installed or a fan provided to assist ventilation. Breathing this air, however, causes no immediate distress and appears to have no injurious effects other than those due to excessive perspiration.

Use of "Sweaters" in Thawed Holes

When the point has been driven "home" it is withdrawn and used to drill another hole, and in this manner the entire face is drilled. The spacing varies from 2 to 4 ft.

at different mines, with 3 ft. as an average. When the point was first invented it was the custom to leave each in place as it was driven; but at some mines it was found that the gravel settled so tightly after thawing that the point could not be withdrawn. It was thus not only in the way of the shovelers, but was unavailable for further use until the thaw was removed. To have 50 or 60 points, each worth $10 to $20, tied up in this manner, and to require another set for putting in another thaw, involved a prohibitive expense for equipment. Thus arose the practice of withdrawing the point as soon as it was driven and replacing it with a "sweater" of ¼- or ⅜-in. pipe (Fig. 9). These sweaters, besides decreasing the investment in equipment, are less in the way of the shovelers, since they can be bent to one side without damage.

Points, while easily bent warm, are difficult to straighten cold and are usually taken to the surface if badly kinked. They may, however, be straightened underground by passing steam through until warm, laying on a plank and striking with a hammer. If this is attempted cold, the steel is very likely to break. Points also frequently become clogged in driving, and if they cannot be cleared by drawing back a foot or two and tapping with the hammer they are withdrawn and a stiff wire—telephone wire is excellent—is run up the steam passage to

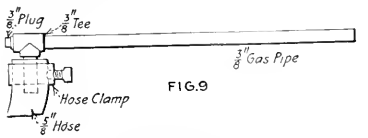

FIG. 9

A "SWEATER"

Solid plug to tap sweater in case it does not enter the point hole easily. Sometimes tee and plug are omitted

dislodge the obstruction. If this does not have the desired result, the point is sent to the surface, it being a waste of time to attempt other than the simplest repairs underground.

Many operators still leave the points in place, but the better practice is to use sweaters. These are placed in the holes drilled by the points and tested with the breath to see that they have not become clogged in entering. They are then carefully "plugged" in the following manner: Jute strips are prepared by rolling up a gunnysack tightly into a cylinder and cutting off 2-in. sections with a sharp axe. The sweater is drawn back a foot or two and one or more jute strips wrapped tightly about it some distance from the end. The sweater is then rammed "home," the jute wrapping being held in place by means of a "calking tool," which is essentially a long-handled, spoon-like affair made to fit roughly over the sweater. More strips are wrapped about the pipe and pushed in against the other if needed. The work is tested by sucking through the pipe with the mouth or by turning on steam. If it is properly done and the gravel is "tight," practically no steam will escape. It is possible in some cases, after the ground is well "warmed up," to open all valves wide to the boiler, or "back the pressure up to the boiler," as the pointmen say. This expression is not based on fact, however; the truth is that some gravel is capable of absorbing steam as fast as the pipe line will deliver it. When water is used for driving, it washes much of the clay, or sediment, out of the gravel around the point and makes it impossible to plug the sweater tightly. Points left in place are also more difficult to plug than are sweaters.

Careful Regulation of Steam Flow

The pipe line having been laid, the lead hoses of the crossheads are connected and the point hoses attached to the sweaters. Steam is then turned on all the sweaters in the face at once. Each sweater and each crosshead has a separate valve, and fine adjustment is therefore possible. The sweaters of each crosshead are regulated so that each takes the same amount of steam, and then the various crossheads are adjusted to equality. Once the valves have been properly adjusted and each sweater is taking exactly its correct share of steam they are left strictly alone, all further regulation being from the line valve or from the boiler. Adjusting the valves to equality is the most difficult part of point work for the beginner. If a valve is the least bit too wide open, that sweater will take too much steam, in which case it will very likely "blow back"; and by robbing its fellows on the same crosshead it may cause some of them to cease feeding or "go dead." The sweater may be withdrawn to observe the exact amount of steam passing through it; but a better way is to judge by putting the hose to the ear, which, however, requires considerable experience.

A series of points or sweaters may be working along perfectly when a temporary decrease in the boiler pressure or some other change in conditions will cause several of them to stop feeding, the steam passage filling with condensed steam. Consequently the points require inspection from time to time, for it is important that a "dead point" be detected at once if the thaw is to be even. In time the point will become cold clear back to the crosshead, when its condition is obvious; but it is better to make sure at an earlier stage by placing the hose to the ear. If the point is dead there will be a gurgling sound, much as is made by blowing under water with a straw; if it is feeding, the steam passes through with a clear hissing sound. Some pointmen also tell whether a point is working properly by taking the hose between the thumb and finger and feeling the "pulse"; if the steam passes through with a recurrent pulsating effect the point is feeding properly. This pulsating effect is interesting, and is probably due to the pressure at the end of the point increasing above normal and forcing the steam out into the gravel with comparative suddenness, thus decreasing the pressure for a moment.

Time and Steam Required for Thawing

The time required for thawing depends on several factors other than the depth of thaw and the closeness of spacing the points, chief among which are the character of the gravel and the effective pressure of steam. If the gravel is loose and comparatively free from clay or sediment, a 5-ft. paystreak can sometimes be thawed in 10 hr. for a distance inward of 9 ft., with the points 3 ft. apart, and with a boiler pressure of 100 lb. As the proportion of clay increases, the time required increases, as much as 40 hr. being necessary to thaw some ground. Of course, if extra-long points are used, or if the depth of pay is unusually great, more time is required. Thus in the Prest ground on Vault Creek the pay extended so far into the roof that it was impracticable to thaw all of it; when the next thaw was put in some of the roof thawed and came down, and was removed with the new thaw.

The amount of steam necessary to run a point varies considerably; but it is usually estimated that one boiler-horsepower will run one point. Thus a 30-hp. boiler should, with good dry wood, run 30 points. C. W. Purington states ("Bull. 263," U. S. Geol. Surv., 1905, p. 92) that the boiler horsepower required to run a point varies from one to two, with an average of 1½. This, however, was before more careful attention to this detail of mining led to the development of more efficient methods, and 1 hp. to the point is probably accurate for the present time. The amount of water taken into the boiler is surprising until one becomes accustomed to it. Thus, a plant on Engineer Creek, thawing about 110 cu.yd. of gravel a day with a 40-hp. boiler, had one ¾-in. injector running continuously and another intermittently while the points were steaming.

Thawed Gravel Should Cool in Place

After the gravel has been thawed it retains its heat for a considerable length of time, and where possible a "thaw" should be left five or six days before removing. This very often is not feasible, however, owing to limitation of working faces, and much gravel is stoped while still warm. In many instances in the past the shovelers have started on a thaw immediately steam was turned off and the waste shoveled back, gravel being shoveled into the wheelbarrows while too warm to hold tightly in the hand. The practice of working in hot ground is one that cannot be too severely condemned; like the roundabout runway and the submarine wheeling plank, it is characteristic of the failure, and not of the paying mine.

Thawing, as noted in the foregoing, is estimated to account for about 20% of the total cost of mining in the Fairbanks district to date—say $6,000,000 in round numbers, on the basis that half the gold extracted was profit. In no other department of drift mining is there so much diversity of practice, and in no other—unless it be sluicing—is there so much room for improvement. Some operators take great pride in their work and have reduced thawing to a science. It is on the methods of such that the most emphasis has been laid in this paper rather than on the haphazard and less commendable method—or lack of method—of others. Labor and fuel are the principal items entering into the cost of thawing, and the introduction of a successful hammer drill for driving, as is promised within a year, will mean a great saving. Until the Government railway makes possible the use of coal for generating steam, however, the cost for fuel must inevitably become greater and greater.

Mineral Production of Great Britain

The British authorities have issued a sheet containing the production of minerals in the United Kingdom from mine workings under the Coal Mines Act and the Metalliferous Mines Act for the year 1914. The figures given do not in all cases represent the total production for the year. Some quantities of important minerals—such as iron ore, limestone, sandstone, slate, clay—are obtained from quarries and open workings under the Quarries Act, the returns from which are not yet available. The totals for coal and for the ores of copper, lead and zinc may be regarded as substantially complete.

Coal Mines

The quantity of coal mined, which was 287,411,869 tons in 1913, fell to 265,643,030 tons in 1914, a decrease of 21,768,839 tons, or 7.6%. The decrease was due chiefly to the falling off in available labor toward the close of the year.

The quantity of minerals other than coal taken out under the Coal Mines Act was, in long tons:

	1913	1914
Barium compounds	4,610	6,265
Clay and shale	457,244	399,810
Fireclay	2,585,763	2,374,068
Igneous rocks	688	634
Iron pyrites	8,864	9,359
Iron ore	7,769,624	7,241,481
Limestone	4,525	6,442
Oil shale	3,280,143	3,268,666
Sandstone, including ganister	144,923	135,718
Total tons	14,199,484	13,442,443

The quantity of ganister included with sandstone in 1914 was 121,168 tons.

Metal Mines

The production of the mines under the Metal Mines Act was as follows, in long tons:

	1913	1914
Arsenic	1,694	1,974
Arsenical pyrites	35	.....
Barium compounds	43,408	39,645
Bauxite	6,055	8,286
Chalk	.....	493
Chert, flint, etc.	5,173	3,844
Clay and shale	133,984	131,190
Copper ore and precipitate	2,705	2,519
Fluorspar	33,833	24,688
Gold ore	4	17
Gravel and sand	12,492	17,331
Gypsum	238,494	220,096
Igneous rocks	57,921	44,299
Iron ore	1,881,853	1,743,011
Iron pyrites	2,463	2,295
Lead ore	24,265	25,988
Lignite	81	300
Limestone	356,316	328,337
Manganese ore	5,393	3,437
Ocher, umber, etc.	6,199	4,463
Rock salt	214,573	189,995
Sandstone	89,718	76,198
Slate	95,271	82,307
Soapstone	40	180
Tin ore (dressed)	6,949	6,622
Uranium ore	95	344
Wolfram ore	182	205
Zinc ore	17,294	15,419
Total tons	3,236,490	2,973,523

Limestone includes 1267 tons of calcspar in 1913, and 630 tons in 1914. In addition to the tin ore reported in 1914, there were 201 tons undressed ore, not included above.

The total of iron ore reported in 1914 from the two classes of mines was 8,984,291 tons. This will be further increased by the quarries report.

Men Employed

The total number of men employed as ordinarily computed was as follows:

	Coal Mines		Metal Mines	
	1913	1914	1913	1914
Under ground	909,834	915,381	16,525	14,426
Above ground	218,056	278,365	10,887	9,283
Total	1,127,890	1,133,746	27,412	23,709

In view of the depletion of mine labor by recruiting in the latter months of the year a special return was made showing the number actually employed on the last pay day in December. The number so returned was 981,264, being 152,182 less than in July and 146,626 less than for the preceding year.

Ferrosilicon and Calcium Carbide will be made at Highlandtown, Md., by the Shawinigan Electro Products Co., a new concern organized as a subsidiary of the Pennsylvania Water & Power Co., of Baltimore.

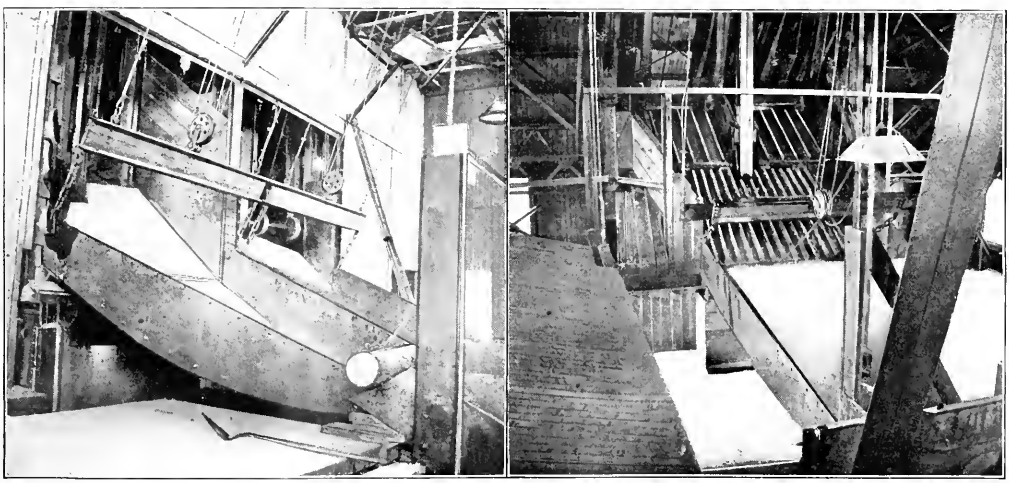
Shaft-Rockhouse Practice in the Copper Country—III

By L. Hall Goodwin*

SYNOPSIS—Rockhouse operations, distinguished from those in the shafthouse, involve handling copper rock and mass copper. Four systems in use, the Calumet & Hecla, the Copper Range, the Quincy and the Hancock. Characteristics, criticisms and advantages of the Calumet & Hecla. The tilting pan. Unusual construction of Ahmeek Nos. 3 and 4 shaft-rockhouse. Development of the Calumet & Hecla crusher. Hancock system uses a traveling link-belt grizzly.

Among the several operations carried on in the shaft-rockhouse, those which have to do with handling copper rock and mass copper are alone rockhouse processes; the shafthouse processes, such as changing conveyors, hoisting water and lowering supplies, have to do with hoisting and are presumably so classified in the cost sheet. It would also seem logical to include handling poor rock in the shafthouse operations, since if the rockhouse were in a detached building it would not handle poor rock except what little was sorted out from the copper rock. It is now intended to review the rockhouse processes of the district as a whole; there are four broad systems which will serve as a classification to which all examples may be referred. Photographs have been shown illustrating the four most recent examples; namely, Mohawk No. 6, Ahmeek Nos. 3-4, North Kearsage No. 1, and Hancock No. 2. It is only necessary to substitute in this list of recent construction the Quincy No. 2, built in 1908, in place of the North Kearsage No. 1, the latter being similar in design and operation to Ahmeek Nos. 3-4, and we have examples covering in a broad way the rockhouse practice of the entire district. Our classification will then be: The Calumet & Hecla system, of which Ahmeek Nos. 3-4 is an example; the Copper Range system, employed in the new Mohawk No. 6; the Quincy system, perfected in Quincy No. 2; and the Hancock system, of which Hancock No. 2 is the only example. The first three of these systems are used largely, almost to the exclusion of other methods; Hancock No. 2 is almost in a class by itself, as the only other instance of conveying copper rock from the hopper bin to the crusher by means of a traveling conveyor was taken up under the topic of detached rockhouses in Part I.

It will be understood that none of these mines uses a hard and fast system in all of its rockhouses. Different rockhouses of the same company, even when they were constructed at about the same time, are differently designed and operated, and often a company will employ entirely different systems; thus, the Copper Range employs the Calumet & Hecla system in two of its rockhouses, and in turn the Isle Royale group, controlled by Calumet & Hecla, uses the Copper Range system.



Ahmeek North Kearsarge

Fig. 7. Arrangements of Tilting Pans

The Calumet & Hecla System

Since the Calumet & Hecla with its subsidiary companies forms the dominating interest among Lake Superior copper mines, its rockhouse methods are used more extensively than those of any other company. The distinctive feature of its system is the tilting pan, a large scoop-shaped steel apron, hinged at its lower end, and tilted by means of friction clutches, so as to feed the rock into the crusher. A grizzly is always used, but its

*Assistant with Allen H. Rogers, 201 Devonshire St., Boston, Mass.

position relative to the tilting pan varies, as it may precede, follow or form an integral part of the pan. In the last case the grizzly bars form the bottom of the pan; this scheme was used at the time the tilting-pan system was being installed and the available space was limited; it is not used where it can be avoided. At the new North Kearsarge shaft-rockhouse the grizzlies precede the pan; at the new Ahmeek Nos. 3-4, however, the grizzlies follow. Two types are shown in Fig. 7. The grizzlies, as is the universal custom in this district, are formed of round iron bars, and in the case of the Calumet & Hecla mines these are set with 4-in. spaces to correspond to the setting of the crusher jaws.

The tilting pans are made of heavy iron, ¾ in. thick on the bottom, ½ in. thick on the sides, and both bottom and sides are protected by a ⅜-in. removable steel liner. The bottom of the pan is not flat, but is laid off on two curves, that at the top of the pan being steeper than that at its mouth; the pans are about 9 ft. wide at the top and less than 4 ft. wide at the mouth; thus they taper toward the mouth, both along the sides and in the pitch of the bottom. When the apron is full of rock and is tilted, this tapering has the effect of causing the rock near the top to push along that at the bottom, which aids in regulating the feed to the crusher.

The pan is raised by an I-beam attached to its top by chains and operated by a winch clutched to a pulley on the main line-shaft, by means of a powerful friction grip. The weight of the pan is partly counterbalanced and the ratio of the pulleys is so large that the tilting of the pan causes no noticeable strain, although the pan contains seven or eight tons of rock.

When the grizzly is placed between the tilting pan and the crusher, as is the case at Ahmeek Nos. 3-4, operations proceed as follows: When copper rock is being hoisted, the skip dumps upon a heavy iron dumping plate, from which the rock slides directly into the tilting pan, which is large enough to hold easily a skip load; the rock is prevented from passing through the pan and into the crusher by means of a rough log of wood suspended by chains across the pan mouth. The rockhouse men now pick out the waste and the mass copper, and when this operation is completed, the log is raised by a friction-clutch arrangement exactly like the one which tilts the pan, and the pan is tilted until the rock begins to slide out of the pan and into the crusher. These operations require the services of two men, one to operate the friction winches, the other to pick out the mass and waste, clean down the grizzly, etc. The large crusher permits the rock to be fed rapidly, and the whole operation of feeding a 7-ton skip load should not consume more than 2½ min.

With the grizzly in other positions, the operation is the same, except that the rock first passes over the grizzly and then the tilting pan feeds directly to the crusher. The plan of having the grizzly follow the pan was adopted at the Ahmeek Nos. 3-4 because the unusual design of that building, to be discussed later, did not permit the grizzlies to be placed before the pan. This arrangement would appear to be particularly advantageous, because the rock is fed to the grizzly slowly, and a much larger proportion of the undersize goes through than is the case where the dumping skip hurls its whole load on the grizzly bars at once. The wear on the bars is also less, since they may be set at a steeper angle; finally a more uniform mixture of stamp rock is secured in the bin because the grizzly is near the crusher. The method is not proving so satisfactory as expected, however, for the reason that the rock as it leaves the pan does not have enough initial velocity to take it over the grizzly, and some of it remains there, causing trouble. Hence the management in later installations will stick to the old custom of having the grizzly precede the pan.

Criticisms of the System

The system is freely criticized, but the criticism usually comes from those who are acquainted only with the earlier developments. Originally the pans were made of comparatively light iron, which required to be frequently renewed; there were two pans and two crushers for each double-compartment shaft—that is, one pan and crusher for each skip; the pans were tilted by air cylinders, which were wasteful of power; and the small crushers used at that time did not permit of rapid feeding. As made at present the pans can resist heavy wear and tear; the friction-clutch mechanism consumes less power and causes less trouble than did the old air lifts; only one pan and one crusher are used for two skips, which reduces the equipment and the large crusher permits rapid feeding.

The most valid criticism would appear to be that no storage capacity is provided before the crusher, so that if anything goes wrong with the single crusher or pan, hoisting must be immediately suspended. The reply to this is that with the massive type of crusher used, and with proper maintenance of other equipment, accidents which would delay hoisting are not supposed to occur. This statement, although it sounds rash, would perhaps appear to be more reasonable after an inspection of the equipment of one of these rockhouses; and as a matter of fact little trouble is caused in this way. It must be remembered that where a hopper bin is used it is never of sufficient size to hold the product of more than an hour or two of hoisting operations, so that it provides storage capacity to carry the rockhouse over minor accidents only. The power consumed in tilting the pan must be considerable, but with the friction clutch the power required is probably not much if any greater than that required for the several inefficient air lifts used where a hopper bin is employed.

Advantages of the System

The great advantages of the system are the small amount of hard work required of the rockhouse men and the speed with which the rock may be fed to the crusher, thus permitting two men to take care of a large tonnage. At the Allouez No. 2 rockhouse, two men easily handle about 500 tons of rock per eight-hour shift, and one of them performs the function of the lander, so that under ordinary conditions there are only two men in the shaft-rockhouse. The new Ahmeek Nos. 3-4 employ five men—that is, two rockhouse men for each shaft and one lander to attend to both shafts, or two and one-half men per shaft. The reason for the small amount of labor required is that the rock feeds to the crusher automatically, and there is no form of chute opening in which the rock can get wedged. All other methods require a bin opening, and it is true that more or less trouble is always encountered in getting the rock through that opening. The principal wearing parts are confined to

the dumping plate, grizzly bars, and the tilting pan; and the heavy construction of these requires only a small amount of repair work to keep the equipment in first-class condition. Friction winches of the present form have in some cases been in place four years, and in no instance has the smaller of the two pulleys had to be renewed or repaired, while in only a few cases have the larger ones needed attention.

Ahmeek Nos. 3-4 Shaft-Rockhouse

The accompanying elevation, Fig. 9, of the new Ahmeek Nos. 3-4 shaft-rockhouse, furnished by H. C. Felver of the local office of the Worden-Allen Co., the builders, will show the general dimensions and the structural features of that building. The plant is a novelty in that it serves two incline shafts, each having two hoisting compartments and serving a mine of large ultimate output. As there are two shafts there are also two tilting pans and two crushers; the stamp-rock bin is of about 2500 tons' live capacity, and is served by two railroad tracks. The whole building is, of course, much larger than the usual incline-shaft headworks, and is comparable to those over the vertical shafts having several hoisting compartments. There were used in its construction 615 tons of structural steel, which compares with about 700 tons in the Tamarack No. 5 vertical. Fig. 8 shows the plant under construction.

The peculiar relations existing between the boundary lines between the Mohawk and Ahmeek companies and the strike of the Kearsarge amygdaloid lode made necessary the adoption of several interesting features in the design of this building. In this vicinity the Ahmeek property is bounded by section lines running north and west from the southeast corner of section 28, and in this southeast corner the property does not carry the outcrop of the Kearsarge lode, but is underlain by it at a depth of roughly 1000 ft. The property line running north from that corner makes an angle of about 52° with a line parallel to the strike of the lode, and the property line running west makes an angle of about 38°. To meet these conditions the company decided to locate two shafts in the extreme southeast corner of the property and to start these shafts from the same point, the northerly one was pointed so as to run along the eastern boundary of the property but diverging from it, the southerly one so as to tap most advantageously the rest of the property. The shafts thus form a V with each other, at an angle of 41° 50'; their dip at the surface is 80°, and they continue on this dip until a depth of 980 ft. is reached, where they assume a curve with a

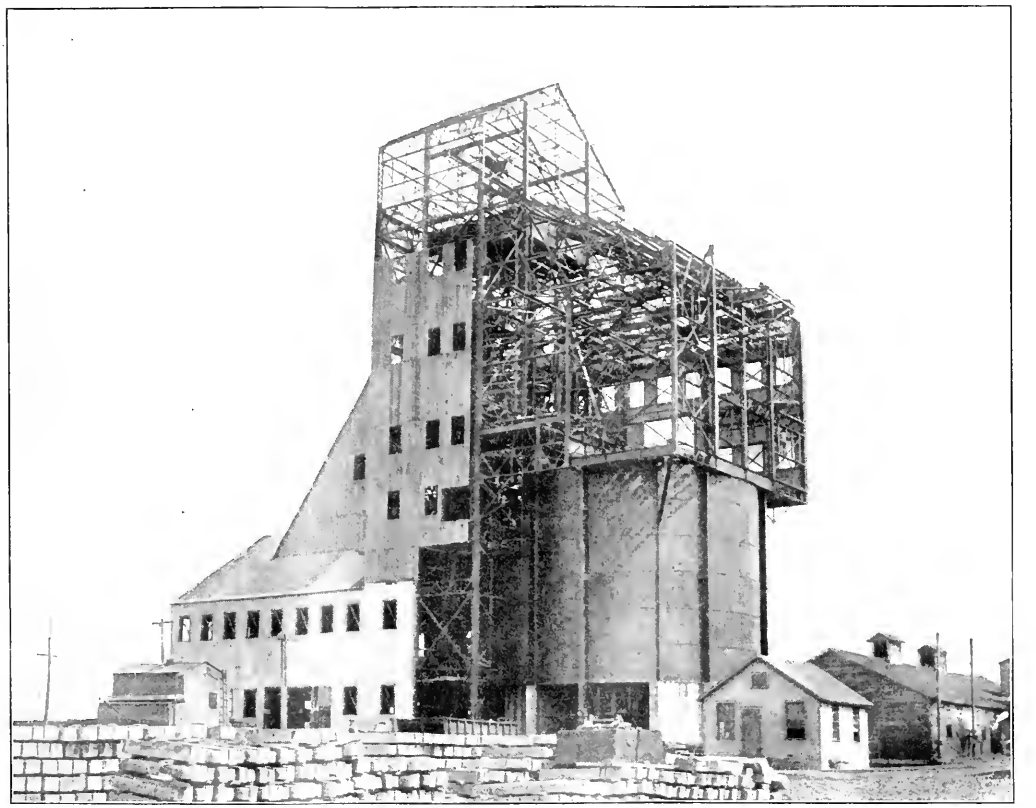


Fig. 8. Ahmeek Nos. 3 and 4. Shaft-Rockhouse during Construction

radius of about 400 ft., which takes them into the lode at a depth of about 1215 ft., after which point they follow the dip of the lode, which is variable, about 31°.

The hoisting plant in this case is on the hanging side of the shaft-rockhouse, because the company does not own the land on the opposite side. This requires a different headframe bracing than the ordinary shaft-rockhouse, the head sheaves being supported by a four-post frame such as is often used over vertical shafts, while the back brace constitutes the sloping roof of the building. The plane passing through the centers of the drums and the hoisting rope in the shaft are not perpendicular to the earth's surface on account of the peculiar arrangement of shafts and hoist; for this reason the head sheaves have to be tilted into a plane which departs 3½° from the perpendicular. This was not allowed for in the structural steel work, but is taken care of by the boxes carrying the sheave axle, one of which is set higher than the other.

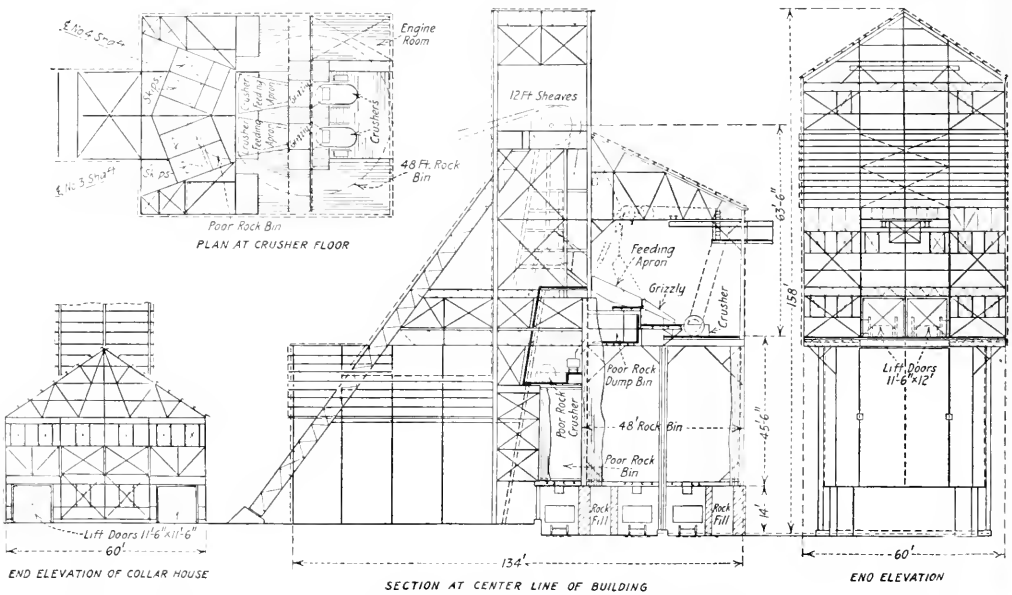

FIG. 9. PLAN AND ELEVATIONS OF AHMEEK NOS. 3 AND 4 SHAFT-ROCKHOUSE SERVING TWO SHAFTS

The design of the building is further complicated by the fact that the skip tracks in the two shafts do not lie in a single plane. Their relative position may be visualized by assuming that the tracks in the two shafts form the elements of adjacent faces of a truncated triangular prism, the angle between these adjacent faces of the prism being 138°. Taken all in all the building must have furnished some interesting problems in structural design.

CALUMET & HECLA CRUSHER

I have already spoken of the new design of Blake crusher made by the Calumet & Hecla. The principal improvement over the usual type of Farrell crusher consists of a one-piece ribbed frame, which is strengthened by three 5-in. bolts running along either side, by three 4-in. bolts across the front end, and by two 4-in. bolts across the rear end. These bolts, as well as the 8-in. hexagonal nuts which tighten them, are put in place hot, and this causes a considerable initial compression in the frame, which renders it extremely resistant to rupture. By this means the weight of the crusher is kept down to 40 tons, which is the same as that of the usual 24x36-in. Farrell crusher, while its size is increased to 24x48 in., and its capacity is also increased.

Minor improvements in design consist of a new toggle and toggle bearing, by which a rolling action in the bearing reduces the wear caused by the usual sliding action; the weight of the pitman is taken from its bearings by springs suspended from a yoke attached to the crusher frame, which causes less wear on the bearings, reduces the power, requires less oil, and eliminates the necessity of cooling the pitman by dripping water, as is often done; the angle between the jaws is increased, which allows a smaller depth of frame for the same jaw opening, and is particularly beneficial in preventing the clogging of the crusher by pieces of mass and in aiding in the extraction of mass that does become wedged between the jaws; this contingency is also guarded against by the simple expedient of marking an arrow on the end of the shaft to show the exact position of the eccentric, so that if the crusher does get clogged, the men may easily tell which way to move the flywheels to open the jaws. The jaws are not corrugated, which also aids in the extraction of mass, as it permits it to be worked sideways.

The ability of this 40-ton crusher to take boulders ranging up to 24x48 in. in size and to stand up for long periods under the strain of reducing them to 4-in. size is enough to commend it highly. It is probable that this crusher has been a large factor in enabling the Calumet & Hecla to perfect its tilting-pan system, by

avoiding the necessity of providing storage capacity before the crusher. The points mentioned as aiding in the extraction of mass copper which has clogged the jaws have been beneficial in reducing the number and length of the temporary shutdowns due to that cause. I was told of one case in which, during the absence of the rockhouse foreman, several men were kept busy for 20 hr. in a vain endeavor to remove a mass by force from the jaws of a crusher, and in so doing nearly removed the crusher from its foundations; the mass was finally removed by turning the flywheels through a quarter revolution and thus loosening the jaws, an operation

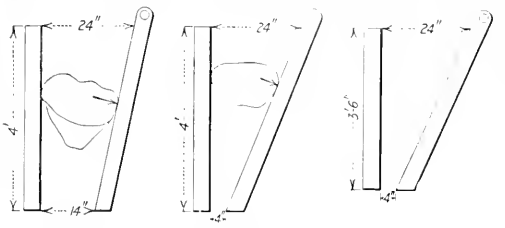

Fig. 10. Development of the Copper-Country Crusher

probably requiring about 15 min. With the slight eccentricity used, it is impossible to tell by inspection which way the flywheels should be turned to loosen the jaws, unless some special provision is made.

The mechanical advantages of this design as compared with earlier ones may best be shown by a comparison of the friction loads, that is, the horsepower required to run the crusher at normal speed when no rock is being crushed. In the case of the new crusher the friction load is about 16 hp., while that of a smaller crusher of the design previously used is 29 hp. This considerable saving is due chiefly to the improved toggle, the suspended pitman, and the lighter weight. The capacity of the crusher is indicated by a test run at one of the amygdaloid rockhouses, during which an average of 105 tons per hr. was crushed for four consecutive hours.

Evolution of the Crusher

The statement made in Part I that the original designs of the Blake crusher were not strong enough to reduce large sizes of rock to 4-in. size in one operation should perhaps be modified to read that people thought they were not strong enough to do this. A few years ago it was thought that no crusher could be made strong enough to resist the strains imposed by this operation, but that this opinion had no basis in fact and that no great amount of thought had been put on the subject will be made evident by a consideration of Fig. 10, which is plotted to scale and which shows diagrammatically the increase in the angle between the two jaws of the crusher in the later designs. *A* represents the original conditions existing at the Calumet & Hecla where it was the practice to break first in a 24x36-in. crusher, set to crush to 14-in. maximum size, and to finish the operation in a 17x24-in. crusher breaking to 4 in. A rock house foreman who took the pains to study the matter decided that the 24x36-in. crushers could be made to reduce large boulders to the 4-in. size in one operation. Perhaps he drew a sketch corresponding to *A* and *B* which showed that a greater strain is produced on the crusher when the jaws are set to break to 14 in. than when they are set to break to 4 in., since in the former case the advance of the swinging jaw is opposed by a force acting nearly perpendicular to its face, while in the latter case this opposing force acts at a smaller angle. The disadvantage of course comes in the smaller capacity of the crusher, but on investigation it was found that during a 10-hr. shift the crushers were actually working about three hours only, so that the smaller capacity was not a disadvantage in this case. When these facts had been established, all of the old 24x36-in. crushers at the Calumet & Hecla mines were remodeled with longer toggles and made to crush to 4 in. in one operation; these crushers are still giving good service.

Hancock No. 2 Shaft-Rockhouse

The Hancock method of handling copper rock cannot be taken as a typical system, because it is at present almost unique among Lake Superior methods, and it was adopted because of special conditions which perhaps will not lead to its being copied extensively. The building and method are worthy of consideration, however, as being thoroughly modern examples of how adverse conditions, such as confronted the Tamarack mine in the early days, have been overcome. The Tamarack property, it will be remembered, carried the underlay of the Calumet & Hecla conglomerate lode at a depth which required some of the deepest shafts in the world to reach. The problem confronting the Hancock was somewhat different, but at this time it will suffice to say that it was necessary to sink a vertical shaft 3600 ft. before it tapped the famous Pewabic lode, from which the neighboring Quincy mine has paid over $20,000,000 in dividends.

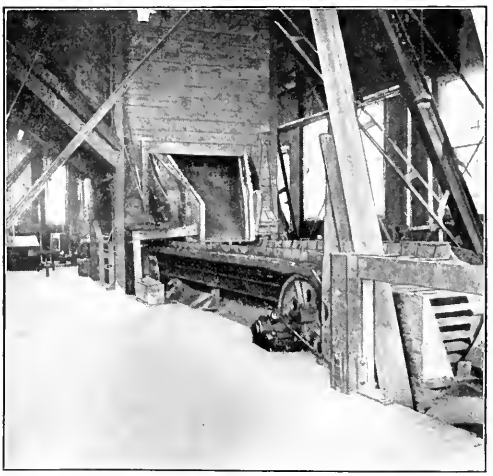

Fig. 11. Link-Belt Grizzly at Hancock No. 2

The Hancock No. 2 shaft has six compartments, in four of which hoisting is done in 8-ton Kimberley skips working in balance. The shaft is not yet working at anything like its ultimate capacity, but hoisting is being regularly conducted. It was this large hoisting capa-

city, together with the fact that the mine is dependent upon an outside railroad for its transportation facilities, which determined the management to provide extra large storage capacity in two steel bins of the usual type, each holding 800 tons of rock. In turn it was this factor of two large bins which determined the method of handling copper rock used.

The four skipways are in a row, and the skips all dump in one direction, the rock going into a small hopper bin with a V-shaped bottom which divides the rock from the dumping skip in two portions, to feed two crushers set on opposite sides of the hopper bin. From the bin, openings 2 ft. high and 4 ft. long having chutes without gate deliver the rock to a link-belt conveyor, Fig. 10, traveling at the rate of 18 ft. per minute, the links of which form grizzlies having 2¾-in. spaces. Each conveyor feeds automatically to a 24x36-in. crusher. Power is furnished by a motor-generator set; each crusher is run by a 50-hp. induction motor, each conveyor by a similar motor of 10 hp. The conveyor motors may be started and stopped easily, so that there is no danger of feeding the crusher too rapidly, and power is not consumed by operating the conveyor when not necessary.

The operation of the system is simple. The rock from the bin spreads itself evenly on the conveyor in a bed about 10 in. thick. A large proportion of the undersize goes through the grizzlies just under the chute from the hopper bin, the remainder of it is easily worked through by the crusher men, who, by using hooks a little, stir the rock sufficiently to cause the undersize to go through.

The advantages and disadvantages of the method are similar to those of the Calumet & Hecla. Although a hopper bin is used, it is too small to furnish storage capacity over any length of time; and the link-belt conveyors consume considerable power. The great advantage comes in the automatic feeding of the rock to the crusher and the small amount of other work required, which enables two men to handle easily a large quantity of rock.

(To be concluded)

Pan-Americanism

By Glen Levin Swiggett*

During 1915 two great Pan-American gatherings will have convened in Washington under the auspices of the United States Government. The first of these, the Pan-American Financial Conference, took place the week of May 24, 1915. In this conference delegates from the Latin-American countries conferred with representative bankers and business men from our nation at the Pan-American Union, on invitation of the Secretary of the Treasury, on financial questions of pertinent interest that must have far-reaching beneficial results to Pan-American banking and commerce.

Of greater interest to the engineering world, however, is the scientific congress that will convene beginning Dec. 27, 1915, and concluding its sessions on Jan. 8, 1916. Through the splendid cooperation of the Latin-American countries the second Pan-American Scientific Congress, held under the auspices of the United States Government through the Department of State, bids fair to be not only thus far the greatest Pan-American Congress, but the most important international scientific congress ever held in the United States. The first congress of this name was held in Santiago, Chile, in 1908. It had its origin in earlier Latin-American scientific congresses; and at the time of the Santiago congress was enlarged through the generous initiative of the Latin-American countries to include the United States. This congress was well attended by visiting delegates from the United States. On its adjournment, entirely unsolicited on the part of the latter, Washington was designated as the place of meeting of the second congress.

This honor has a singular appeal to our nation at this time. The present European war has brought the Western Hemisphere suddenly face to face with grave economic problems that invite the serious attention of scientists and experts in the various fields of applied science. The scientific congress will concern itself with the constructive discussion of these, as well as with the contributions in the domain of pure science, wherein great advance has been made since the last congress held in Santiago, Chile.

The significance of the congress is greatly enhanced through the international reputation of the persons chosen to arrange for the programs of the different sections of the congress, most of whom have an intimate, first-hand acquaintance with the local resources, development and scientific interest in the various Latin-American countries.

Washington offers unusual advantages for a congress of this nature. It enjoys an enviable distinction among the world capitals for the keen scientific interest and investigation in its various Federal bureaus, the varied and extensive nature of its libraries and museums, the beauty of its buildings and the growing importance of detached but semi-official institutions and bureaus engaged in work of international scope. Among these none occupies a position of greater importance than the Pan-American Union, the governing board of which, composed of the diplomatic representatives of the participating Latin-American countries, with the Secretary of State of the United States as ex-officio chairman, has signally honored the Second Pan-American Scientific Congress by authorizing the use of its beautiful building for the office and sessions of the congress. The board also, in response to the request of the President and the Secretary of State of the United States, has authorized John Barrett, the director-general of the Pan-American Union, to act as secretary-general of the scientific congress. He has doubtless done more than any other American in the establishment of commerce and comity among the republics of the Western world.

*Assistant secretary of the Congress.

Record Rate of Loading Iron Ore

Special Correspondence

In May a new loading record was made at the Duluth, Missabe & Northern docks. Ten boats were loaded in one 10-hr. shift, taking away from the pocket 86,000 tons of ore. During the same period 1213 cars were unloaded into the ore pockets.

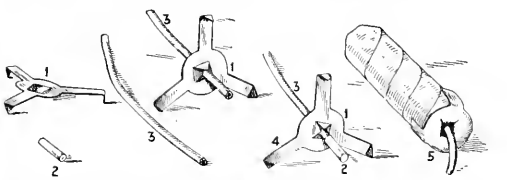
A new record has been made this month at the same docks, when a total of 109,800 tons was loaded in 9 hr. and 45 min., 15 boats being loaded and sent away. The average rate of loading was 11,262 tons per hour and the average loading time per boat was 39 min.

Details of Practical Mining

Clip for Detonator

The method of inserting the detonating cap in a stick of dynamite so that it will have no tendency to pull out is often a subject of both trouble and discussion. The best method advocated by the manufacturers of explosives is to insert the primer in a hole made in the powder by a pointed stick, after having unfolded the end of the paraffin paper wrapper, and then gathering the covering around the fuse and tying with a string. There is no objection to this method except the time required to do it. It is a fussy job to do this. The miner is liable to find that his fingers are all thumbs when it comes to tying a knot in a fine piece of string, and although he and the foreman may both start out with more or less zeal, patience is soon exhausted, enthusiasm wanes and back they go to the old method of lacing the fuse through the stick of dynamite, with all the attendant risks of burning out holes and the usual disadvantageous results.

In the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa, Vol. 14, page 366, W. Cullen suggests a clip he has devised that is extremely simple and accomplishes all of the much-to-be-desired results with a minimum of trouble and effort. This clip consists of a



CLIP FOR PRIMER CARTRIDGE, SHOWING, 1, CLIP; 2, CAP; 3, FUSE; 4, ALL ASSEMBLED; 5, ASSEMBLED WITH CARTRIDGE

circular sheet of thin malleable metal, like copper, with three equidistant arms projecting from the circumference and a star-shaped, pronged hole punched in the center. Each of the equidistant arms has its end sharply pointed and the point turned up. In use, the fuse with the detonating cap attached is pushed through the hole, the detonator is crimped on the fuse by pliers in the usual way, and the cap is then inserted in the hole punched through the end of the stick of powder, wrapping paper and all. Then the arms are folded down about the cartridge and the pronged points piercing the wrapping paper clinch the clip so that it cannot be pulled off the stick of powder. This prevents the detonating cap and fuse from being pulled out of the star-shaped hole.

This method is much quicker than lacing the fuse through the stick of dynamite and is much better in every way. These clips can be stamped out of thin sheet copper at the mine or in any local machine shop, and it is expected that they will soon be put on the market by an Eastern manufacturing concern. Their use is advocated, and the method of using is fully shown in the accompanying illustration.

Cold-Air Intake Duct for Air Compressors

It has often been observed that the output of an air compressor is greater in winter than in summer; that is, it seems that a machine which has had to "hustle" to furnish air in summer, may be able to maintain the required pressure at a reduced speed during the winter. The reason for this is often asked, and R. S. Bayard, in *Power*, May 25, 1915, discusses the matter in detail.

This difference can be observed only when the compressor takes its air through a duct leading from the outside air, because it is due to the effect of the difference of air temperature between the compressor intake and that air about the compressor.

Imagine a cylinder having a perfectly tight piston held, we will say, at midstroke, and the half-cylinder full of air at atmospheric pressure and at a temperature of 60° F. The atmospheric pressure is, with 30-in. barometer, 14.7 lb. per sq.in. With the piston held rigidly and leak-tight, assume that we can heat the cylinder so that the air inside will become 100° F. This will cause the air to expand and try to occupy more space, but if the piston will not move, the air cannot expand, so it will increase in pressure. Mathematically, the pressure produced in this way will be

$$14.7 \times \frac{100 + 460}{60 + 460} = 14.7 \times \frac{560}{520} = 15.84 \textit{ lb. per sq.in.}$$

That is, the new pressure, absolute, will be equal to the first pressure, absolute, multiplied by the ratio of the absolute temperatures.

If, in the cylinder we are considering, the piston is allowed to move as the air expands and if it has no friction, so that the air pressure does not increase, the final volume will be larger than the original volume in the ratio of the absolute temperatures. If the original volume was, say, 10 cu.ft., the final volume after the piston has moved, due to increase of air temperature, is

$$10 \times \frac{100 + 460}{60 + 460} = 10 \times \frac{560}{520} = 10.77 \textit{ cu.ft.}$$

At the usual room temperatures (about 520° F. absolute) the increase of volume is, roughly, 1% for every 5° F. increase of temperature.

Let us see how the foregoing applies to a compressor plant. Irrespective of the outside temperature, the air in the shop pipe lines will be nearly at the temperature of the room by the time it reaches the tool. Suppose in winter this temperature averages 68° F. and that the air finally reaches the tool at this temperature. If the compressor takes in 1000 cu.ft. of free air (air at atmospheric temperature and pressure) directly from the room, it will also deliver 1000 cu.ft. of free air at the tool, because the final temperature is the same as that at which it entered the compressor.

In summer the same conditions apply as long as the compressor takes its air from the same room in which the compressed air is used; but if the compressor is provided

with an intake duct leading from the outside air, the result will be quite different. First, consider the winter condition. Suppose the shop temperature averages 68° F. and the outside air 30° F. If the air is used at 68°, its volume will be considerably greater than the volume taken into the compressor from the outside air at 30°. If it requires 1000 cu.ft. of free air per minute at shop temperature to run the tools, the compressor will have to take in only

$$1000 \times \frac{30 + 460}{68 + 460} = 1000 + \frac{490}{528} = 929 \; cu.ft.$$

which is a saving of over 7% in air capacity, speed and horsepower. In summer, when the outside temperature is practically the same as the temperature indoors, there would be no saving by using the intake duct except, as is often the case, when the compressor takes its air supply directly from the hot engine room. Thus it is seen that the compressor would run at a speed about 7% lower in winter than in summer. The colder the climate, the more pronounced this effect would become.

An actual case where the application of an intake duct to a compressor represented an appreciable saving recently came to my attention. An air compressor furnishing an average of 2500 cu.ft. of free air per minute to a machine shop took its supply from the basement of the engine room, where all the year round the air, heated by a network of steam pipes, averaged 95° F., while the shop averaged 70° F. During the winter months the outside air averaged 32° F., and in summer 70°. Based upon the average consumption of 2500 cu.ft. per min. for 10 hr. a day, the air used amounted to an average of

$$2500 \times 60 \times 10 = 1{,}500{,}000 \; cu.ft.$$

per day at the shop end.

As the compressor-intake temperature averaged 95° F., the compressor was obliged to run fast enough to take in

$$1{,}500{,}000 \times \frac{95 + 460}{70 + 460} = 1{,}500{,}000 \times \frac{555}{530}$$
$$= 1{,}570{,}500 \; cu.ft.$$

of engine-room air per day.

The cost of compressed air in this plant was found to be 2.8c. per 1000 cu.ft. at the compressor. Thus the cost of furnishing air to the shop was

$$\frac{1{,}570{,}500}{1000} \times 0.028 = \$43.97 \; per \; day$$

By putting in an intake duct and furnishing air to the compressor at 30° F. in winter, the compressor could have been run slower and would have had to take in only

$$1{,}500{,}000 \times \frac{30 + 460}{70 + 460} = 1{,}500{,}000 \times \frac{490}{530}$$
$$= 1{,}387{,}000 \; cu.ft. \; per \; day$$

At a cost of 2.8c. per 1000 cu.ft. at the compressor intake, the average cost of air for the plant during winter would then be

$$\frac{1{,}387{,}000}{1000} \times 0.028 = \$38.84 \; per \; day$$

During the summer, when the outside and inside temperatures both averaged 70° F., the compressor would take in only the amount used in the shop, or 1,500,000 cu.ft., which at the cost of 2.8c. per 1000 cu.ft. at compressor intake would be

$$\frac{1{,}500{,}000}{1000} \times 0.028 = \$42 \; per \; day$$

With the intake duct in use we then have a daily cost for air of $38.84 for winter and $42 for summer. The average for the year may then be taken at $40.42 per day, as against $43.96 with the compressor taking air from the engine-room basement.

During a working year of 300 days, the annual cost for air would then compare:

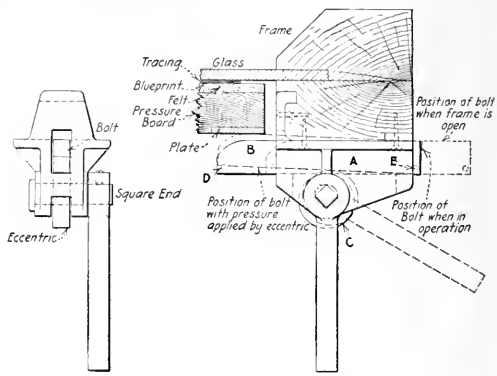
Without intake duct	$43.96 × 300 = $13,188
With intake duct	40.42 × 300 = 12,126
Giving a net saving with the duct of	$1,062

Capitalized at 10%, this would justify installing an intake duct costing $10,620. As this figure approaches more nearly the cost of the compressor than it does the cost of the duct, the conclusion is obvious.

Incidentally, the saving of $1062 per year amounts to more than 8% of the yearly cost for air. It certainly appears to be worth while to install an air-intake duct under such conditions.

Clamp for Blueprint Frame

F. J. Hibberd in the *American Machinist* describes a clamp for blueprint frames for use in those drafting-rooms where the electric blueprinting machine has not been introduced, but where the old-style sun frame still exists. There are many devices used for clamping the pressure board down on the back of the frame so as to give the necessary close contact between the tracing and



Details of Blueprint Clamp

the glass. The common door-bolt, which is the device generally used, is a most unsatisfactory means of securing this contact.

The illustration shows an improved method. It is composed of a brass bracket *A*, which is fastened by screws to the side of the frame. It has a sliding piece *B*, which can be moved in and out by hand like a "bolt" and is so designated in the illustration.

Underneath this bolt is an eccentric disk *C*, which is fastened to a pin and has a hand lever fitted in its square end. When the bolt is shot into place, the lever is pulled over to the right, as shown by the dotted lines, and the eccentric disk forces the bolt up in the direction of the pressure board, thereby pressing the tracing against the glass of the frame. There are pegs, *D* and *E*, to limit the movement of the bolt. Of course in actual use the whole appliance is reversed and remains so till the clamping is complete.

Engineering Notes and Methods at Miami

By H. P. Bowen*

SYNOPSIS—Kinks about underground surveying, best instruments, tapes, reels, etc., to use; methods of taking and keeping notes, filing them for office use and recording them on maps and assay plans; use of tracing cloth, blue-print and black-print papers.

The graduate of any one of our technical schools leaves college with a more or less clear idea of how to perform certain field and office engineering work with extreme accuracy. All the training he has received tends to that one end. He is theoretical rather than practical in his work, and it is generally some time before he begins to realize how large a structure of practice must be erected upon his small foundation of theory.

Practical engineering is a science of approximations. Absolute accuracy is as impossible here as elsewhere, and near-accuracy is often economically wrong. The first point to be decided in the laying out of any work is to what degree of accuracy the work in question should be done; the second, how to do it as quickly as possible with the least work and the least chance of error. For example, the elevation of a certain point is required. This may be obtained in the three following ways: The elevation within from 5 to 10 ft. can often be scaled off a contour map; an accuracy within 1 or 2 ft. may be obtained by a stadia shot or two from a known bench mark; or the elevation may be accurately determined by running a line of levels to the point in question. While more accurate, either of the latter methods would mean time and work wasted were only an approximate elevation desired.

Everyone makes some errors in his work. They must be found before the work has gone far enough to cause trouble. An engineer cannot afford to let pass any opportunity of checking his work. No matter how monotonous the work, one must not fall into the mistake of doing it mechanically, or some error will creep in and pass by unnoticed.

If in plotting or checking a piece of work it does not *seem right*, it should be checked and rechecked, preferably by someone else, for the chances are in favor of there being a mistake in it.

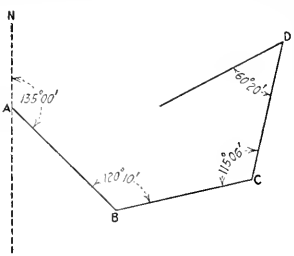
Every engineer has a favorite among the various makes of surveying instruments, but it must be borne in mind that a good engineer can do good work with a poor instrument, while a poor one cannot do good work with the best instrument made. The class of the instrument and the shape it is in will affect only the time and care necessary to do the work right.

Ordinary underground work consists mostly of putting in line-plugs for drifts and crosscuts, lining up timbering and a certain amount of leveling. The class of transit I have found most convenient for this work is a small instrument with U-shaped standards and no compass box. The chance of error in reading the horizontal circle has been lessened by having it graduated only one way from right to left and from 0 to 360 deg. It has a horizontal, vertical and two diagonal cross-wires and two stadia wires. Cross-hairs and graduations are made coarser than usual to make them easily read in the poor light underground. For shaft plumbing and long connections a larger and more finely graduated instrument is used.

*Care of Miami Copper Co., Miami, Ariz.

Tapes and Reels

The question of tapes and reels is one that is hard to decide. I have yet to see a reel that is perfectly satisfactory and will stand up under the hard usage it receives underground. Reels for 500-ft. tapes are too heavy and clumsy to carry around. All reels fall down when used underground on account of the grit cutting out the bearing surfaces. For the latter work a reel should be of the size necessary to take a tape 50 ft. longer than the one used. This will keep it from binding with the dirt and grit it picks up. For surface work a 500-ft. wire tape $\frac{1}{8}$ in. wide graduated on brass sleeves for every foot of its length is used. This is better than a shorter tape, especially in a rough country. For underground surveying a heavy $\frac{5}{8}$-in. tape heavily etched to feet, tenths, and hundredths is giving the best satisfaction. A thin tape will not stand the rough usage and a $\frac{1}{8}$-in. tape, besides being difficult to read, crystallizes after some use and becomes brittle. For the samplers, heavy $\frac{5}{8}$-in. tapes etched to feet are preferable. Graduations on babbitt, copper or brass soon wear off and cannot be read.



A Traverse by Azimuths

The bearing is carried underground by jiggling in line with two wires suspended in the shaft. A quick method of "jiggling in" is as follows: Set the instrument tripod as near as possible in line with the two wires, having two of its legs parallel with and one at right angles to the line of the wires. Put on the transit head and level up the instrument. Now if the transit is nearly in line as it should be, it is possible to jiggle in by raising or lowering the tripod leg which is at right angles to the line of the wires, and then leveling up the instrument. By moving the tripod leg instead of the transit head it is possible to move the transit a minute distance, and the subsequent leveling lessens this. Size No. 6 piano wire is used for plumbing raises and shafts up to 200 ft. and size 8 for greater distances. Weights for plumbing can be made from short lengths of iron pipe filled with lead. Slots cut in the pipe will permit the insertion of tin vanes, which should project about an inch beyond the pipe, causing the weight to come quickly to rest when in use.

Our underground stations in the Miami company's mines consist of spads either driven in caps or in plugs set in holes drilled in the rock. In the former case such a station is never used for work of importance without checking back on stations set in the rock. A cap will sooner or later move more or less, no matter how solid the timbering may appear. In an entirely timbered working, an intermediate point put in line with any two stations will prove by lining up at any time whether any one of the three points has moved. In such workings permanent stations can often be made by punching a point in a moil driven into the floor. Spads are made from No. 4½ horseshoe nails. Larger sizes split the plugs. The heads are hammered flat and slots for the plumb-bob cord cut with a hacksaw.

Every angle in an underground traverse is doubled and both the original and doubled reading are recorded on cards carried for that purpose. These cards are carried in a tin holder and are filed away in the office daily.

Bearings by Azimuths

In the hurry of underground work, mistakes in calculations, especially those that must be made on the ground, are easily made. A method that will make the calculations almost entirely mechanical will result in the fewest errors. For this reason we figure our bearings by azimuths. By the azimuth of any course I mean the horizontal angle turned to the right between the first station, on a course due north, and any other station on the course. To get the azimuth of any course in a traverse, take the azimuth of the preceding course from back sight to station set on, add 180° and the horizontal angle read to the right between the station set on, back sight and fore sight, and the result will be the azimuth required, unless it is greater than 360°. In this case subtract 360° if the result is not greater than 720°, and 720° if it is, and the difference will be the azimuth.

To illustrate, take the courses in the figure, *A, B, C, D, E,* then:

		Deg.	Min.
Azimuth AB	=	135	00
		180	00
Angle ABC	=	120	10
		435	10
		360	00
Azimuth BC	=	75	10
		180	00
Angle BCD	=	115	06
		370	16
		360	00
Azimuth CD	=	10	16
		180	00
Angle CDE		60	20
Azimuth DE	=	250	36

To obtain the bearings from the azimuths is simple, as the following will show:

When the azimuth is from 0 to 90° azimuth = N.E. bearing.
When the azimuth is from 90 to 180 180 — Az. = S. E. bearing.
When the azimuth is from 180 to 270 Az — 180 = S.W. bearing.
When the azimuth is from 270 to 360 360 — Az. = N.W. bearing.

Station and Level Designations

All stations are numbered by numbers stamped on 1¼-in. copper disks, which are nailed to the plugs or caps. Aluminum tags soon become covered with a white coating, probably a sulphate of aluminum, making it difficult and sometimes impossible to read them. Stations on each level are numbered from zero up in the order in which they are put in, and in the case of replacing a station an entirely new number is used to avoid confusion.

Drifts and crosscuts are plotted on the mine maps once a month from rights and lefts taken at that time. This can be done most rapidly by using four men. Plumb-bobs are hung from two stations and the tape stretched between them and held. The third man measures the distance from the tape to the walls of the drift with a stick graduated to feet and calls them out to the fourth man, who records them along with distance of each reading from the starting point and the name of the level drift and stations used. A record will read as follows:

370 LEVEL, N. 600 W. 400 N.
Stations 69-70

Distance from Station, Ft.	Distance to Left, Ft.	Distance to Right, Ft.
10	2	3
25	4	2
30	6	1
50	10 S.E. cor. raise	3
54	2	3

Stopes are measured up every few days and sketched on cross-section cards carried in a loose-leaf holder. These are then transferred to the office maps and the cards filed.

Up to the present time there have been about three thousand working places in the mine, and this necessitates a certain definite arrangement both for matter of record and to designate the working. The levels are named from the distance they are to the surface in the shaft that first entered the orebody. A zero point was established on all levels at this shaft and the workings named in accordance with their relation to it. The name of each working is composed of three parts—first, the level; second, the distance north, east, south, or west from the zero point, and, third, the direction in which the heading is being driven.

Following are the names of some of the drifts: 370 Level E 200 N; Level E; Level N 300 W 50 E; Level W 150 S.

If the footage of each drift were measured from the intersection of the coördinates at its starting point, it would result in double-measuring every crossing. To obviate this, the workings running north and south or east and west from the zero point are measured from that point and all others from the sides of the drift from which they start. This also renders it possible for the samplers to measure and sample the drifts before transit lines are put in.

Vertical raises are measured from the top of the rail in the drift from which they start.

Mapping and Office Kinks

Assay plans and sections made on a scale of 40 ft. to the inch will enable the assay percentages to be entered inside of the lines of the drifts in case such percentages do not consist of more than three figures. At this property assay plans are made of each level and sublevel, and vertical sections are made on the 50-ft. coördinates each way. These sections face the east and north.

As the greater part of our tracings are used for the purpose of making blue or white prints, colored inks are not used on them with but one exception. Old timbering that is to be replaced is sometimes represented by green ink lines. These show as faint blurred lines on the blueprints.

Where very many tracings are to be made it will pay to buy tracing cloth cut in sheets, with the border, title, and even the coördinates, printed. The cloth costs but a few cents a sheet, and besides the saving in time will

more than pay for itself in the saving of tracing cloth ordinarily lost in cutting.

All paper and tracing cloth shrink after being unrolled, due probably to the tension applied in rolling them up. For large tracings or drawings where accuracy is necessary cut the paper or cloth to the required size and leave it loosely rolled for several days before using. In the case of tracing cloth, strip off the selvage edges before setting it away.

To plot coördinates, lay off one of the lines and erect two perpendiculars to it at opposite ends of the drawing; measure equal distances along these perpendiculars and draw a fourth line parallel to the first completing the quadrilateral. Check this up, subdivide the sides and draw in the coördinates. If this is not all done at one sitting the coördinates will be found to be out, as the paper or tracing cloth will stretch or shrink from day to day, especially during changes in the weather.

Blueprint papers vary in cost, due principally to the quality of the paper used in its manufacture rather than to any difference in the emulsion used. Some of the cheap papers are not tough and tear easily when wet. Blueprint papers are classed as rapid, electric-rapid, or regular, according to the time necessary to print them. In bright sunlight this varies in this locality from 3 min. for the regular to 20 sec. for the electric-rapid. By using the latter a saving in time is effected and prints can be made quickly on cloudy days if required. More care must be taken in using the more rapid papers to keep them from being exposed, so they do not keep so well as the slower kinds.

Direct black-print papers and cloths are printed directly from the tracings, and after being finished by washing in water give blue-black lines on a white background. They are much more expensive than blueprint papers and cloths, but are very useful for many purposes. Additions in pencil or drawing inks may be made to these prints, and they may be colored with either water colors or crayons. Black-print papers and cloths require from 4- to 8-min. exposure in the sun—the cloth a little longer than the paper; and it is not usually advisable to try to get a print on a cloudy day. Under-exposure leaves the ground purple after washing and in an over-exposed print the heavy lines are a light gray and the light ones print out. All white-print paper I have used becomes brittle if kept several months before using. Most, if not all, of this paper is imported from Germany, and the difficulty in obtaining paper that has not been kept in stock until it is brittle and worthless has kept many from using it. Apparently the cloth does not deteriorate with age.

An easy and rapid way of coloring white prints and drawings is by the use of wax crayons and gasoline. Go lightly over the space to be colored with the crayon, moisten a piece of cloth with gasoline and by rubbing it over the colored surface smooth the color and extend it to the edges of the space to be colored. If the color is smeared beyond the required limits it can be removed by a pencil eraser. The probable explanation is that the crayon, being a mixture of wax and ground pigment, has the wax dissolved by the gasoline, which leaves the pigment as an impalpable powder to be rubbed evenly over the surface. Some colors work much better than others, namely, the yellows, purples, slates and greens.

Convenient weights for holding down drawings can be made from 4x4-in. canvas bags filled with shot.

In an office of any size much time can be saved by the use of a tracing table. This consists of a glass-topped table under which are placed several large electric lights (we use 100-watt tungstens). With this it is even possible to trace through heavy cloth-backed drawing paper. The number of uses to which such a table may be put will be found to increase from day to day.

When it is necessary to put coördinates on a tracing it will be found advisable to place them on the opposite side of the cloth from the rest of the map. If this is done the coördinates will not be affected by any erasures.

These comprise some of our methods in use at the present time, for they are constantly changing. Frequently slight modifications are made to adopt a better method to our particular needs. Often a better procedure is adopted and more rarely a new one is originated and developed.

Missouri's New Mining Law

By A. L. H. Street*

At the recently adjourned session of the Missouri Legislature the mining laws of that state were increased by several different acts. One of the measures provides for official inspection of mines other than coal mines, to determine whether dust is present in the air in quantities injurious to miners. If such a condition is found, provision is made for requiring the owner or operator to install and maintain an independent water line, fully equipped and in good serviceable working order, leading up to the face of any and all drifts where such dust is produced, or so close to the face of the drifts that by the use of suitable hose extension or sprinkling attachments (to be supplied by the owner of the mine), the mineral or earth in and adjoining the face of the drifts can be sprinkled by water from the pipe line. It is made the duty of every person drilling, squibbing or blasting in such mine to keep the face, surface and drill holes in such drifts moist to such a degree as to prevent as far as possible dust rising from the workings. Violation of any provision of this act is punishable by a fine of from $5 to $50.

Another law requires owners and operators of lead and zinc mines to provide suitable dressing rooms with lockers for the use of employees. Adequate washing facilities and benches must also be afforded, and the rooms must be kept properly heated. A fine of from $5 to $25 may be assessed for disobedience of this act. Under a separate act, owners or operators of lead and zinc mines are bound to provide sanitary drinking devices if 10 or more men are employed.

Another law makes it the duty of the chief state mine inspector and his assistants to stop the operation of any mine or part thereof, where poisonous damps exist, where rotten ropes or unsafe cages are used or where a safe escapeway is not provided for all employees. A penalty of fine or imprisonment, or both, is prescribed for infractions of this act.

The Dexter White Caps Mining Co. of Manhattan, Manhattan, Nev., for the year ended Mar. 31, 1915, reports a production of 3106 tons of ore having a gross value of $56,272. The receipts from the sale of ore and royalties amounted to $45,867. The expenses were $65,683, thereby making a deficit of $19,816. Current liabilities amounted to $17,669 over current assets.

Details of Milling and Smelting

Smelting Storage-Battery Sediment

By Walter C. Smith*

Several years ago I had occasion to treat considerable storage-battery sediment or mud in a 10-in. circular lead blast furnace. The charge for furnace averaged 850 lb. of ores, fluxes and returned slags. Fuel varied from 10% to 14% of weight of charge.

With normal conditions we had little or no trouble from the furnace top working hot, but whenever the charge carried 100 lb. or more of battery sediment the furnace would develop a hot top. Increasing the percentage of coke, lowering the blast pressure or wetting down charges would not correct the hot top. The furnace ran well, the slags were hot, tuyeres were bright, and had plenty of coke at tuyere level. By substituting any other lead-bearing material for battery sediment, the top would cool rapidly; replacing battery sediment on charge would, within one hour, develop a hot top accompanied by heavy fume losses.

The cause of this hot top was a matter of some discussion, the conclusion being that battery sediment, consisting principally of lead peroxide (PbO_2), breaks down under moderate temperature into litharge (PbO) and oxygen (O_2). This liberated oxygen immediately combines with CO in gases to form CO_2 and generates a large amount of heat at or near top of charge, thereby rapidly heating charge until a hot top develops, with no apparent increase of fuel consumption.

To prove this a small amount of battery sediment was slowly heated in a tube; well below a red heat, the reddish-brown PbO_2 changed to yellow PbO and a test of the gas showed the presence of large amounts of oxygen.

I finally treated battery sediment as follows: First, adding 75 lb. or less to each charge, wetting charge thoroughly; second, heating sediment in roasting furnace or kettle until it had turned yellow and then charging into furnace as lead ore.

Delta Crucible Tongs

The New Jersey Foundry & Machine Co., of 90 West St., New York, has put a new type of crucible tongs on the market which is so constructed as to take a six-point bearing on each side of the crucible, regardless of wear. This is attained by having three curved plates mounted on a three-armed frame, which has play enough in its mounting always to bring these three plates against the crucible.

In addition each of the plates has a concave surface, and this, with a little play in the individual mounting, insures a bearing of at least two points for each plate. This sextuple bearing should eliminate a great deal of premature cracking of crucibles through poorly fitting tongs.

Smelting Data of British Columbia Copper Co.

Frederick K. Brunton, in describing* the British Columbia Copper Co.'s smelting plant at Greenwood, B. C., gives some interesting operating data of that works prior to its closing in 1914 on account of the decline in the price of copper. The company smelts the lowest-grade ore of any North American smelting works, the average copper content being 0.85%. The plant treats about 2250 tons per day, or 17.5 tons per man per day.

The equipment includes three blast furnaces and two converting stands. Two of the blast furnaces are 51x360 in. at the tuyeres and the other is 51x240 in. The vertical distance from feed floor to the center of the tuyeres is 16 ft. The 30-ft. furnaces have 72 tuyeres, 4 in. in diameter but bushed to 3¼ in., and receives about 25,000 cu.ft. of air per minute at 16- to 24-oz. pressure.

A typical furnace charge is shown in the accompanying table. The most variable factor is the Motherlode ore, which sometimes changes abruptly from a lime gangue to an iron gangue carrying about 30% magnetite, so that the furnaces require constant watching. The 5000-lb. charge shown gave 4300 lb. of slag that would carry 0.23% Cu, or about 10 lb. of copper, leaving 34.7 lb. for the matte, which required one-fourth of its weight, or 8.7 lb., of sulphur. By reason of the poor construction of the furnaces for handling ores so low in sulphur, 88%, or 160 lb., of the sulphur was volatilized in the furnace, leaving 23 lb. for the matte. Since the copper took 8.7 lb. of sulphur, there was left for iron 14.3 lb. of sulphur, requiring 1.75 times its weight, or 25 lb. of iron. The matte, therefore, contained: Cu, 34.7; S, 23.0; and Fe, 25.0 lb., and assayed 42% Cu. The slag ran approximately as follows: SiO_2, 42.7; Fe, 19.7; CaO, 21.2; Al_2O_3, 9.0; and Cu, 0.23%.

Cooling water for jackets, gallons per minute	21 0
Men per 8-hr. shift	1.65
Matte, per cent. of total charge	38 to 45
Slag, per cent. SiO_2	13 to 20
Slag, per cent. Fe	20 to 26
Slag, per cent. CaO	6 to 9
Slag, per cent. Al_2O_3	

*"The British Columbia Copper Co.'s Smelter, Greenwood, B. C.," a paper to be read before the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

The labor required in the furnace department per shift is: One shift boss at $5.25, three furnacemen at $4, three furnace helpers at $3, one slag motorman at $3.10, one slag switchman at $3, three charge motormen at $3.15, three head loaders at $3.15, three second loaders at $3, one feeder at $4, one bin man at $2.75, one power-house man at $3.40—a total of 21 men and of $70.70 in wages per shift. In addition there are on day shift only, four men in the briquetting plant and four men on slag-track grading at a total daily wage of $23.50. These two crews are used when needed in general roustabout work so that not all of their time was really chargeable to furnace work.

Powdered Coal

At the seventh annual convention of the International Railway Fuel Association, W. L. Robinson, supervisor of fuel consumption of the Baltimore & Ohio R.R., presented a paper outlining the advantages that might result from the use of powdered coal in locomotive furnaces, from which the following costs of pulverizing are taken:

The cost of preparing powdered coal will vary with the cost for the raw coal and its moisture content. However, a general average from available data covering periods of the past five to ten years at cement and metallurgical plants has made it possible to present the following conservative estimate, assuming the cost of the raw coal at from $1 to $2 per short ton, and that it will require crushing and have a moisture content of from 5 to 10 per cent. when placed in the drier:

Capacity of Plant in Short Tons per Hour	Average Total Cost for Preparation per Short Ton
2	From 25 to 50c.
3	From 20 to 45c.
4	From 16 to 40c.
5	From 14 to 35c.
10	From 12 to 30c.
25	From 10 to 20c.

The fuel reqnired for drying the coal will average from 1 to 2% of the coal dried. The distribution of the total may be approximately stated as follows:

Fuel for drying	10%
Power for operation	30%
Labor	30%
Maintenance and supplies	25%
Interest, taxes, insurance and depreciation	5%
Total	100%

The cost of preparing powdered coal should be more than offset by the ability to utilize mine refuse and sweepings, run-of-mine, screenings and slack grades of coal that cannot be used to good advantage otherwise, and inferior grades of sub-bituminous coals, lignite and peat of relatively lower cost per ton than the readily salable commercial fuels.

Coal in a finely divided or powdered state represents the most advanced method for producing perfect combustion. While a cubic inch of solid coal exposes only 6 sq.in. for absorption and liberation of heat, a cubic inch of powdered coal exposes from 20 to 25 sq.ft., which enables the more uniform gas production from the volatile matter in the coal and the more prompt and perfect intermingling of gas and air, thereby improving combustion and reducing smoke. Furthermore, there is no cooling of the fire by heavy intermittent charges of fresh coal, as is the case with hand or stoker firing on grates.

Powdered coal may be burned by either of two generally defined methods—the long-flame method, constituting a progressive burning of the coal such as is employed in cement and openhearth furnaces, and the short-flame method, which is the latest development and is used in metallurgical and similar metal-heating work or under boilers where a similar furnace volume obtains.

Welding Up Scrap Nickel Anodes*

Some important experiments in the welding of nickel anodes by the oxyacetylene process have just been concluded in the large plating department of the Prest-O-Lite Co., Inc., at its Indianapolis plant.

The anodes used by the Prest-O-Lite Co., Inc., are castings of 90% nickel, 8% carbon and 2% iron. They are elliptical bars, approximately 1½x3½ in. in cross-section and 30 in. long, and weigh about 30 lb. Their market value varies between 46c. and 50c. per lb.

By welding up old anodes which have been in the solution, and which have a junk value of between 22c. and 25c. per lb., the company is now converting its entire pile of scrap nickel into what are practically new anodes at a total cost for gas and labor of less than 6c. per lb. This estimate is based on a recent test at Indianapolis in which 421 lb. of scrap anodes were welded up at the following cost:

463 cu.ft. oxygen, at 2c.	$9.26
480 cu.ft. acetylene, at 2c.	9.60
24-hr. labor, at 25c.	6.00
Total	$24.86

In view of the fact that this test was made before any experience in the operation had been gained, it is apparent that better results and greater savings are sure to be the result of practice.

The method of handling this operation is about as follows: As the anodes are eaten away by the solution they are turned over to an oxyacetylene welder, who "tacks" on scraps of old anodes by welding to increase the surface.

The welding flame is also employed to remove the brass hooks which are used to support the anodes while in solution. Under the intense heat of the oxyacetylene flame (approximately 6300° F.) the solder melts away rapidly, leaving a pure nickel bar, which is later welded up.

No flux is employed, as this has been found to be unnecessary. The pieces of scrap are simply melted on or "fused" together, using another piece of nickel as a filling rod. The welding process is a great benefit in obtaining perfect fusion, which is essential, as all joints must have electrical conductivity equal to that of new anodes.

Another great advantage is the fact that no skill or experience in the art of oxyacetylene welding is required to weld up scrap nickel anodes: in fact any workman with average intelligence can do the work without any previous knowledge of the process. The apparatus needed to do the work is inexpensive.

Many other attempts have been made to utilize scrap nickel anodes, the most common practice being to drill holes through several pieces and bind them together by means of lead rivets. This method depends on the contact of the wire or rivet and the piece of scrap to conduct the current, and is therefore of uncertain value, and in many cases a flat failure. If for any reason the contact is bad and offers too much resistance to the current of electricity, the metal will not dissolve.

*From data furnished by the manufacturers.

The Cost of Doing Things

La Rose Consolidated

The La Rose Consolidated Mines Co., Cobalt, Ont., shows a combined profit of $208,939 for 1914 and dividend payments aggregating $171,000. Shipments totaled 1995.4 tons, averaging $333.20 in value per ton, after deducting $90,584 for smelting charges. The total reported cost of producing silver was 37.2c. per oz., made up of 23.08c. for mining, 9.69c. for concentrating, 7.42c. for marketing, 0.77c. for depreciation, 0.09c. for general expenses, and 0.64c. for advances to the University mines—a total of 41.69c., less a credit of 4.49c. for ground rents, discount and interest. The marketing expense was made up of 5.07% of the gross value of the ore for deductions on silver, 4.39% for treatment charges, 2.85% for freight and 1.65% for assaying and sampling, etc., or 13.96% total, based on $727,075, the gross value of the ore, including cobalt, paid for. Dividends paid to date by the La Rose Mines amount to $6,519,409 and by the La Rose Consolidated, $5,162,326. The mill treated 54,020 dry tons of ore and produced 1,271.76 dry tons of concentrates containing an average of 443 oz. of silver per ton. The average assay of mill heads was 13.12 oz., and tailings averaged 2.75 oz., indicating an extraction of 79.5%. Mill costs were $2.45 per ton milled. Ore reserves are estimated to contain 47,464 tons having a net value of $166,781. It is stated that the property has been almost exhausted of high-grade ore.

*

East Butte

The East Butte Copper Mining Co., Butte, Mont., for 1914 reports a net surplus of $222,252 on operations. Copper production amounted to 9,175,579 lb. from 72,853 wet tons of ore, or 71,918 dry tons from the company's mines, and 39,074 dry tons of custom ore. There were also produced 242,347 oz. of silver and 2219 oz. of gold. The gross value of metals shipped was $1,291,675, and other income amounted to $163,779, which made a total income of $1,455,454. Operating expenses amounted to $1,048,856; interest payments, $36,500; depreciation and losses, $11,744; additions to equipment, $71,002; and exploration and development, $65,099. The cost per pound of copper was 11.11c. Mining, including development, averaged $5.39 per ton of ore. The main shaft was sunk 185 ft., making a total depth of 1770 ft. Owing to the war the property only operated 220 days in 1914.

*

International Nickel

The report of the International Nickel Co. for the year ended Mar. 31, 1915, shows a net profit of $5,598,071, after deducting all expenses, depreciation, exhaustion of minerals and all other charges. During the year $595,376 was expended for additional property. Dividends amounting to $534,756 were paid on preferred stock and dividends on common stock aggregated $4,753,937. The consolidated balance sheet shows current assets of $11,117,881 and current liabilities amounting to $2,770,073. The number of stockholders increased from 3752 to 4465 during the year.

*

Chino Copper in 1914

The report for 1914 of the Chino Copper Co., Hurley, N. M., shows a production of 53,999,928 lb. of copper from 1,926,705 tons of ore. Dividend payments amounted to $2,169,065, while the actual amount available for dividend payments from 1914 operations was $2,298,246. The mill treated 1,907,300 tons averaging 2.1151% copper, and 19,405 tons were shipped direct to the smelters. The average net yield in refined copper per ton of ore was about 28 lb. The accompanying table gives a summary of Chino's production for the last three years:

Year	Tons of Ore Treated	Yield of Refined Cu per Ton	Total Lb. Refined Cu Produced	Ore Reserves — Tons Ore	Ore Reserves — Average per Ton
1912	1,122,666	24.7 lb.	27,776,088	90,000,000	36 lb.
1913	1,942,760	26.0 lb.	50,511,661	90,000,000	36 lb.
1914	1,926,705	28.0 lb.	53,999,928	90,270,155	35 lb.

The company owns 2645 acres of mining claims, of which 2412 acres are patented. In addition to this land the company owns 160 acres of agricultural land adjoining its mining claims. Including various water rights in connection with its mill site, the company also owns or controls 18,074 acres at Hurley. There were issued 9400 shares of capital stock during the year for the conversion of the remaining outstanding first mortgage bonds. The total outstanding capital stock now amounts to 869,940 shares. Dividends to date have aggregated $4,088,135. The profit as shown in the report for 1914 was $3,222,519, but other expenditures for deferred operations, bond redemption and investments reduced the amount available for dividends to $2,298,246 as shown in the following statement, which has been prepared in order that the financial transactions as shown by the statements in the report may be easily understood:

TOTAL RECEIPTS AND TOTAL EXPENDITURES OF THE CHINO COPPER CO. DURING 1914

Receipts		
From sale of metal products		$7,247,197
From miscellaneous sources		179,588
From capital stock at par value		47,000
From premiums on sale of capital stock		187,850
Total receipts from all sources		$7,661,635
Expenditures		
Expenditures charged to operations	$4,172,374	
Bond interest and advances paid	31,832	
Property account	1,645	
Construction and equipment	400,625	
Development	34,553	
Deferred stripping	484,178	
Investments	1,680	
Bonds redeemed	236,500	
Total expenditures	$5,363,388	
Paid out in dividends	2,169,065	
Added to quick assets	129,182	
To balance with total receipts		$7,661,635
Balance of quick assets at end of 1913		$2,298,529
Balance of quick assets at end of 1914		2,427,711
Increase in quick assets in 1914		$129,182
Dividends paid in 1914		2,169,065
Amount actually available from 1914		$2,298,247

ANALYSIS OF TOTAL RECEIPTS AND EXPENDITURES

Receipts from operations—current and deferred:		
From sale 53,999,928 lb. of copper at 13.325c.		$7,195,423
From gold produced		51,774
From miscellaneous income		179,588
Total operating income		$7,426,785
Current operations:		
Mining and milling	$1,473,553	
Treatment, refining, freight	2,048,004	
Selling commission	72,805	
Stripping	578,012	
Total operating costs reported		4,172,374
Total income reported		$3,254,411
Less interest and advances paid on bonds		31,832
Net profit shown in report for 1914		$3,222,579
Deferred expenditures to operations:		
For property account	$1,645	
Construction and equipment	400,626	
For development	34,553	
For deferred stripping	484,178	
Total deferred charges to capital accounts		$921,002
Balance over current and deferred expenditures		$2,301,577
Other expenditures:		
Bonds redeemed	$236,500	
Investments	1,680	
	$238,180	
Less receipts from capital stock	234,850	
Net amount paid out from earnings		3,330
Amount from 1914 actually available		$2,298,247
Dividends paid		2,169,065
Balance added to quick assets		$129,182

The total amount of ore and waste removed by steam shovels was 4,192,009 cu.yd. of material in place; 3,173,717 cu.yd. of this was stripping and the remainder was equivalent to 2,114,910 tons of ore. All material removed to date by steam shovels amounts to 13,014,416 cu.yd. in place, of which 10,188,246 cu.yd. was stripping, and the remainder was equivalent to 5,770,356 tons of ore. Of this ore 720,295 tons has been stored in the stock pile. The average cost of steam shovel work was 36.52c. per cu.yd. for all material moved during the year. The cost of handling waste alone was 33.47c. per cu.yd. The cost per ton of waste handled was 16.12c., while the cost of handling ore was 22.13c. There is a total of 24.039 miles of track used in and about the mine in connection with steam-shovel work, of which 23.223 miles was in use on Jan. 1, 1915.

During the first seven months of the year the mill operated 95.3% of possible time for all sections. Owing to curtailment on account of the war, the mill was operated on 66% of possible time during the remaining five months. During the first period the mill averaged 1345 tons per day per section and 1085 tons for the five-month period. During the year the entire plant averaged 5225 tons per day and treated 1,907,300 dry tons. A total of 147,925 tons of concentrates was produced, which corresponds to a ratio of 12.89 tons of ore to 1 of concentrates. The average grade of concentrates was 18.505%, and the mill extraction was 67.858%. The average milling cost was 55.01c. per ton of ore.

Ore reserves are estimated to contain 90,270,155 tons of fully developed ore averaging 1.15% copper. On the basis of operating costs reported, which do not include depreciation, the net cost of producing copper after crediting gold contents and miscellaneous earnings was 7.35c. per lb. as compared with a cost of 8.5c. per lb. reported for the previous year.

※

The Franklin Mining Co., Houghton, Mich., for 1914 reports that the only production for the year came from the test-sampling of 7324 tons of rock, which yielded 93,283 lb. of copper. The total expenses were $140,018, and receipts amounted to $357,449, including assessments Nos. 1, 2 and 3. After deducting a deficit for 1913 a balance of $117,165 remained in the surplus account at the end of the year.

Tennessee Copper Co. in 1914

The report of the Tennessee Copper Co., Copperhill, Tenn., for 1914 shows a production of 12,871,113 lb. of refined copper from 185,051 tons of company ore smelted. Net profits for the year, including acid-plant earnings and earnings from all other sources, amounted to $751,893.

This amount was distributed as follows: Dividends, $600,000; reserve for general depreciation, $100,000; reserve for Federal income tax, $1126; and addition to surplus account, $50,767. Dividends to date aggregate $4,465,250. A record of the production from the company's ore for 1901 to 1914 inclusive shows that 4,978,349 tons of ore have been mined, 4,961,673 tons smelted and 155,493,546 lb. of copper produced. Ore reserves are estimated to contain 5,390,661 tons averaging 26.54 lb. of recoverable copper. The cost per ton of ore, not including refining, was $2.74725 made up as follows:

	Per Ton
Mine development	$0.04957
Mining	.37813
Railway expense	.05027
General expense	.18932
Smelting expense	1.31677
Converter expense	.16319
Total	$2.74725

The total cost of producing refined copper was 11.40c. per lb., not crediting the sales of sulphuric acid nor the values of copper in flue dust. The acid plant produced 210,163 tons of 60° Baumé acid. The smelting plant treated 724,822 tons of ore and flux with 38,726 tons of coke. The company has now reduced its bonded indebtedness to $800,000. It now has about 2000 stockholders.

※

Tamarack

The Tamarack Mining Co., Calumet, Mich., for 1914 reports a production of 1,074,808 lb. of copper which it sold for 12.8c. a lb. The mine operated at a loss of $174,908. The following table gives a comparison of operations for the last four years:

	1911	1912	1913	1914
Tons of rock treated	392,338	421,385	227,563	57,410
Pounds of mineral	12,793,430	12,118,038	6,206,295	1,743,145
Pounds of refined copper	7,494,077	7,908,745	4,168,743	1,074,808
Per cent. of refined copper in mineral	58.58	65.26	67.17	61.66
Refined copper per ton of rock treated, lb.	19.1	18.8	18.3	18.7
Cost per pound:				
Mining	14.07c.	11.90c.	15.35c.	24.00c.
Construction	.06c.	....	....	3.28c.
Smelting, freight, commissions, office, etc.	1.23c.	1.11c.	1.25c.	1.80c.
Interest	20c.	.14c.	....	....
Total cost per lb.	15.56c.	13.15c.	16.60c.	29.08c.
Cost of mining, transportation, stamping and taxes, per ton of rock	$2.69	$2.23	$2.81	$4.49

※

Beaver Consolidated

For the year ended Feb. 28, 1915, the Beaver Consolidated Mines, Cobalt, Ont., shows a production of 900,000 oz. of silver, of which 390,878 oz. were sold. The remainder was held in storage by the smelters. The mill treated 26,724 tons of ore, from which 347.95 tons of concentrates were produced containing 415,707 oz. of silver. A profit of $254,768 is shown in the financial statements before providing for depreciation amounting to $13,728. Dividends for the year amounted to $60,000. The cost of production was 21.54c. per oz. of silver.

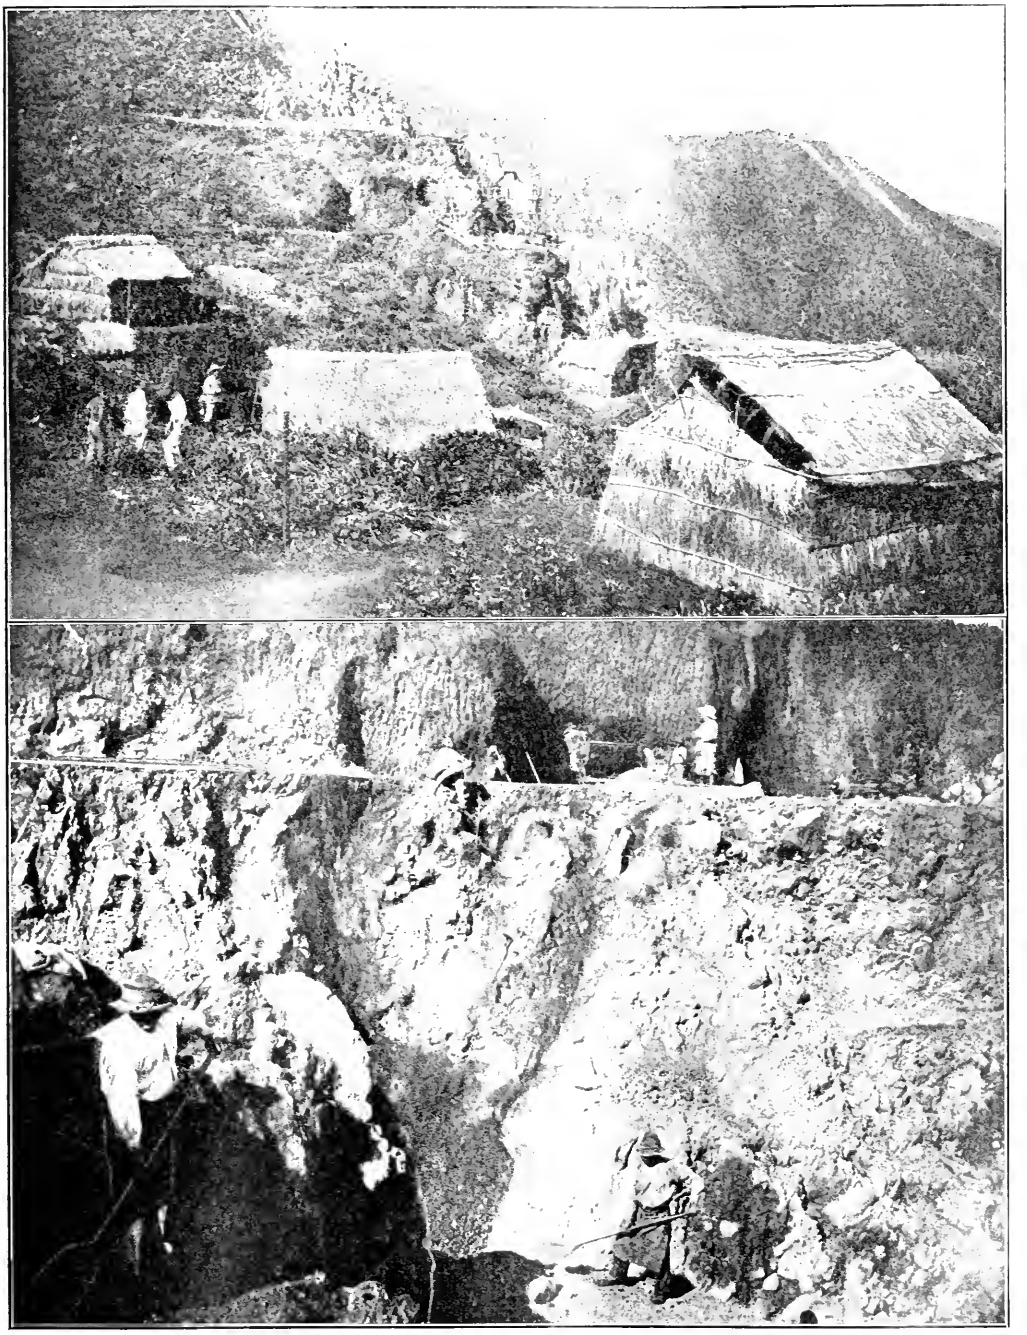
"Le Nickel," New Caledonia

Famous nickel mines controlled by a French company. The upper view shows the shore and landing at La Mission, the town embracing the company's plant. The lower view shows the works



"LE NICKEL," NEW CALEDONIA

Two views of the Bornet mine, near La Mission, New Caledonia. Mines are connected with the works by a 17-km. aërial tramway over which 50,000 tons yearly are transported. The pylons are 22-25 m. high. The company has refineries at Havre and Glasgow

Correspondence and Discussion

Tin Smelting in Bolivi

I refer to the editorial comment on the article by Mr. Lamb in the JOURNAL of Apr. 3, 1915. As ex-director of the Departmental School of Mining and Engineering of the Republic of Bolivia I can assure the editor that any business in tin done by the Yankees in this country will have to be solely on the basis of properties owned.

The kind of mines which capitalists usually look for—those in working order and with developed ore—are not to be found in Bolivia. Here everybody lives from hand to mouth, without bothering about the morrow; and although one may wish to develop a mine properly, he will not find either competent technical direction or the capital or credit required. The result is that even the large businesses have not the intrinsic value which they appear to have, nor is there life or prosperity assured even for two or three years. Anyone who wishes to succeed here must force his future with his own hand, beginning with the clearing of the titles to property, rectification of boundary lines, investigations, preparation of mines and living quarters, and finishing with the necessary skill for ore treatment.

I know of virgin lands which are good and available for development on a large scale; I know also of abandoned mines which would provide a profit if they were properly developed. The sooner the problem is tackled the sooner and surer will be the success. One cannot lose by giving serious study to the problem and disregarding the gratuitous information given by travelers for pleasure. Anyone considering work of this kind should possess a knowledge of the Spanish language, in order to treat directly with the people, and also to be able to appreciate the value of the facts presented. If such person is capable, cultivated, and will come recommended to me, I will lend him my aid and experience and knowledge, together with much positive information.

Only a short time ago there arrived here a merchant who has passed through New York. Apparently enthused by the prospects which had developed for a tin market, he asked me for information about mines and mining business. From my point of view he was wasting time, and it is a loss of time to bother with going into details with people who are unknown. However I do not doubt that Mr. Burrage might have entered into a splendid business if he had installed his smelteries in Bolivia, taking advantage of the hydraulic power available—for example, that of Pilcomayo.

The greater part of our miners have no resources and are eternally pushed by necessity. Consequently, they deliver their products to the first buyer. Even the companies of some importance prefer to liquidate their concentrates or sorted ore to local buyers for cash, instead of waiting for the results of a sale in Europe, which, in normal times, means a delay of about five months. Taking into account the great saving of freight and insurances, saving in sacks, loss of mineral or ore, and penalties, more or less unjust, for moisture, etc., you can understand why a country which contains the raw material in abundance has not yet arrived at the solution of the problem of the metallurgy of tin. The truth is simply that we in Bolivia are the toy of circumstances and conditions will not change until intelligent technical and commercial skill, conscientious energy and capital in adequate quantities shall enter into and take part in our mineral industry.

JOSÉ JACKOWSKI.

Casilla No. 120, Potosí, Bolivia.

Difference in Buying Zinc and Lead Ores

The producer of small lots of lead ore (galena) throughout the Missouri-Kansas-Oklahoma district sells his output at a certain figure per 1000 lb. and usually gets as much as the operator who sells carload lots. But in the production of zinc ore a different condition entirely exists, the small producer invariably being forced to take a much lower price per ton than the larger producer. A striking example of the wide variation in price between small lots and carload lots of zinc ore has been noted recently since ore prices have soared to such high levels. Carload shipments of uniform grades of blende concentrate have brought as high as $135, basis of 60% metallic zinc, whereas the company selling only a few tons would receive only $85 or $90.

Why there should be such a wide variation in zinc and virtually no difference in lead is explained through the fact that all lead ores of this district respond to simple smelting processes, whereas there is a big difference in the various lots of zinc concentrates from the different small mines, and a conglomeration of such concentrates does not yield as readily to the zinc-smelting process as would concentrates more uniform in character. Zinc smelters do not like to purchase odd lots of concentrates for the reason that their retorts are adapted to a certain character of charge and by varying the metallic composition of this charge the highest efficiency in metal recovery cannot be attained, and also the life of the retort is shortened. This condition explains why the heavy producers of uniform grades of zinc concentrate find a ready market at good prices for their output, whereas the small producer sometimes finds it difficult to dispose of his product even at a greatly reduced price.

A uniform grade of concentrate, whether it be high or low, is the kind that finds the ready market. Certain smelters demand only those concentrates that run high in metallic zinc and low in iron and with a minimum or total absence of lead. The presence of iron is not so undesirable as lead and certain smelters prefer a low-grade concentrate with plenty of iron. Lead content in the zinc is undesirable to all smelters whether they are users of high- or low-grade concentrates.

Competitive bidding for district concentrates is the method of purchasing as there are no contracts in use.

Blende is sold on a 60% metallic basis; calamine on a 40% basis, and galena on an 80% basis.

Joplin, Mo., June 10, 1915. L. L. Wittich.

Kitchen Assaying

Some months ago there appeared in the Situations Wanted column of a New York daily newspaper a notice to the effect that a certain lady was prepared to enter the service of a mining company. It appeared that her qualifications were almost unlimited, including bookkeeping, cooking, assaying, surveying, etc.

If there is to be any great demand for such versatile talent, the correspondence schools, publishers of cookbooks and editors of pin-money pages of the Ladies' Home & Camp Companion Journals should take such steps as may be necessary to disseminate useful information pertaining to the duties of those fortunate or unfortunate female persons who are compelled, either by their roving instincts or by the vicissitudes of fortune, to follow mining as a profession. As a hint the following sample is respectfully submitted:

Rapid Copper Analysis

Break the ore to about the size of half a thimble. Take four bread-pans and place edge to edge in the form of a hot cross-bun. Pour the ore gently with a slight tango-step motion, so that each pan will receive an equal share. Discard contents of two opposite corner pans. Mix contents of remaining two pans and repeat until about one large teacupful of ore remains. Pulverize in a clean coffee mill or meat chopper to fineness of percolator coffee. Mix thoroughly on oilcloth of kitchen table.

Take one leveled teaspoonful of the ore and place in a teacup. Add one tablespoonful of spirit of niter, a few drops of spirit of salt and a pinch of hyperoxymuriate of potash. Bring almost to a boil and then set (not sit) on the back of the range to simmer for about half an hour. Then add gently three dessert-spoonfuls of pure water. Allow to cool and add volatile alkali to suit smell.

Line a glass funnel with a cone of unsized paper porous enough to allow liquids to pass through it. Set the funnel over a milk bottle with a capacity of exactly one pint (this is perhaps 34.6592 cu.in. or possibly 28.875 cu.in., but the absolute value is unimportant).

Pour the contents of the teacup into the paper cone, leaving the dregs or grounds until the last pouring. Wash out cup with boiling water, adding the dish-water to the slops in the funnel. Keep on washing until the pint bottle is nearly full. A mark placed on the bottle will be found convenient to indicate the same quantity of liquid in each case.

To measure the percentage of copper in the ore a set of bottles should be prepared beforehand, using some ore that is known to contain an exact percentage of copper, such as 4%.

Use one batch for a 4% shade. Use another batch and add an extra pint of clear water and mix thoroughly. Then one pint of the mixture will give a 2% shade. Dilute the other pint again for a 1% shade.

For an 8% shade, use two teaspoonfuls of the 4% ore and double everything but the wash water, keeping the total liquid quantity down to one pint, or to the mark on the pint bottle. Beer bottles, whisky bottles, grape-juice bottles, etc., will serve, provided they are of clear glass without tint and all of the same size.

For those who find difficulty in understanding what "percentage of copper in an ore" means, a special recipe may be devised to show the number of grains, pennyweights, etc., in a stone of ore. Sugar is often sold by the stone, ¼ stone being 3½ pounds. So it will be an easy matter to balance the ore with four errands of granulated sugar. (When I was a little boy an errand of sugar was always 3½ pounds.)

Resuming the chemico-culinary topic, it may be stated that to guess the answer to a copper assay or analysis by this easy method one merely causes the sample bottle to promenade up and down the kitchen shelf opposite the stock set, and the color is matched as in selecting ribbons.

By this method a good consulting kitchen-mechanic can guess at the percentage almost as accurately as it can be estimated by a khaki-clad high-priced technical graduate.

Correspondence-School Graduates

In much of the technical and pseudo-technical matter which I have written in the past have been injected a few bits of what was intended to be humor in order to relieve the monotonous tone which might otherwise have prevailed.

Some unkind person has suggested that I cherish a feeling of malicious hatred toward correspondence schools. The imputation is false. Correspondence schools have performed a great service for humanity and have also paid me real money for some of the text-books which I had the pleasure of writing and revising.

What I do abhor is a conceited dolt who, having completed a correspondence course, imagines his dictum to be the last word in science—the final test, as it were. Such a bore is immeasurably more insufferable than a recent college graduate who announces that he is about to put the world on the high-speed gear and cut out the muffler. The latter individual has enough sense to know that the world is "hep" to his game of bluff or else he is sufficiently congenial to "kid" the world into taking him seriously now and then.

The correspondence school question may be summed up briefly in a metaphor—the best incubator in the world will not hatch a cold-storage egg.

New York, June 8, 1915. William B. McKinlay.

Belgian Trade after the War

I should like to inform the Journal readers that several competent Belgian business men have created an organization having a double object: (1) To introduce in Belgium, as soon as the war is over, all American products and manufactures; (2) to employ as agents, representatives, etc., a large number of Belgian manufacturers and business men, who have been partly ruined but still possess enough capital and can give the necessary guarantees as agents, dealers, etc.

Willy Lamot.

Shardhighs, Halstead, Essex, England, June 1, 1915

Mining Conditions in China

By F. Lynwood Garrison*

SYNOPSIS—Consideration of some established facts about the Chinese and their country. Its civilization is the most ancient and its people have developed an anti-military spirit. The country has great agricultural and mineral resources, and economic awakening is likely to make it one of the most important.

The present visit of the Chinese Trade Commission to the United States is likely to renew interest and stimulate our desire to know more of the mineral resources of that great country. As has always been the case when educated Chinamen honor us with a visit this commission is making a most excellent impression upon all who have been so fortunate as to meet its members.

No one who has lived and worked in China, who has striven to know its people and understand their views of life, can have failed to be impressed most favorably by their high character as well as their soundness and saneness of intellect. Despite the fact that my own work in China was cut short by the Boxer troubles of 1900, my interest in this great people has not ceased or flagged, and I have never had reason to change the high opinion of their character first impressions gave me. But in order better to understand the Chinese and China it is desirable, even at the risk of restating well-known facts, for us to consider a moment certain fundamental conditions that are essential to a proper appreciation of the subject as a whole.

Antiquity of Chinese Civilization

Chinese civilization has endured for something like 5000 years. Had the oldest of the other civilizations, the evidence of which archaeologists are now digging up out of dust heaps, endured to the present it is doubtful if any of them would be as old today as is the Chinese nation. Notwithstanding this great age, the Chinese continue to be a strong and virile people; how strong and how vigorous one needs to have lived among them to realize fully and to appreciate that antiquity does not necessarily connote decadence, or that ingrained distrust and disgust for militarism indicate degeneracy. The Chinese in a sense have always been an essentially agricultural people; despite the fact that a few notable mechanical inventions appear to have had their origin with them, the mechanic arts as such appear never to have flourished, to have been encouraged or to have played any notable part in the history of Chinese civilization. Herein lies the essential difference between Oriental and Occidental, or perhaps it would be more correct to say between Mongolian and European, culture, and it brings us to a realization of how this terrible war in Europe is mocking us.

Have we not with smug complacency been sending for many years missionaries to the "heathen" Chinese, and on the whole have they not been kindly received? The Chinese tell us: "These missionaries are very good people, they help us in many ways, and we welcome them, for they heal our sick, cure our maimed and teach our children many useful things; but we are not perfectly sure their ethical views and understandings of life are any sounder or better than our own. With your machines you can do many things we cannot, and you have thus added vastly to your personal comforts and wealth, but we are not certain that in consequence you are any happier or better off. Your educational system is perhaps a stupendous success if the world is to be simply a factory, but we fear it may prove a monstrous failure if the object happens to be more than that. In short, does your Western system of education give sanity to life or even protect it?"

I profess no greater insight into the oriental mind than that possessed by the average Westener, but it seems to me not so difficult to get some fleeting glimpses into its depths if we take the trouble. We all know in our hearts that might as expressed by mere physical force is not necessarily right, and that defenseless China of today is the only great nation in the world that does not believe in physical force as a vehicle through which to assert might. The Chinese do not now and never have asked anything of the world but to live and let live in peace. But that it is a fatuous, dangerous policy in this present state of world civilization we are all now willing to admit. That the Chinese may change this policy and become part of the restless, ruthless mechanical world is not altogether improbable, although I myself believe and almost hope it is unlikely. With this theme in mind let us briefly consider a few facts regarding the natural resources which China can call upon when she sees fit to change her economic policies.

Geography and Topography of China

China with its dependencies has an extent of something like 4,000,000 square miles, and as every geologist knows no such great area of the earth's surface traversed by great mountain chains and intersected with large river valleys exists that does not give promise of extensive mineral deposits. The area of China proper is about 1,400,000 square miles, 200,000 of which are comprised within the alluvial plains of the Yangtze and Yellow Rivers; the remaining 1,200,000 is hilly or mountainous. It has been assumed by some writers that but little is known of the mineral resources of China. As I will endeavor to show, such is not the case, and their exploitation by the Chinese themselves is by no means a new thing. As long ago as the time of Marco Polo in the 13th Century, the Chinese were using what is described as "a black stone which they dig out of the ground and burn like firewood," which of course was coal, and its use thus far antedates any recognition of its value in Europe or in any other country. In fact, as a general statement it may be said that from time immemorial the Chinese have been utilizing their mineral deposits in a small way, but that it has only been within recent years they have come to any sense of realization of their extent and commercial importance.

Chinese Coal Deposits

About the first inkling the Western world received of the vast extent of China's coal fields was from the obser-

*Mining engineer, Philadelphia, Penn.

vations of the American geologist, Raphael Pumpelly, whose reports were published by the Smithsonian Institution in 1866. Three years previously this remarkable man ascended the Yangtze River to Central Hunan and to the frontier of Szechwan; in 1863-64 he examined the coal fields west of Peking and made journeys in northern China and southern Mongolia.

Pumpelly was followed a few years later (1870) by the German scholar and geologist, Baron von Richthofen, who spent many years traveling about China, and whose valuable observations and maps were published in five large volumes. Richthofen's deductions are in the main probably reliable, but the practical conclusions he drew therefrom are open to doubt. He was a geologist of profound learning and some of his work in this country, particularly that connected with the Comstock lode, is notably good.* Coal beds, especially those of anthracitic character, have a habit of faulting, folding and pinching out, or being eroded away, and Richthofen appears to have been somewhat misled in judging the volume and extent of such deposits by the size and character of the outcrops. Our American Government geologists did much the same thing in Alaska. Hence it is evident even the best of geologists and mining engineers, who are unfamiliar with coal mining and estimating, are likely to ascribe an undue continuity and size to coal beds when judged solely from superficial appearances. Moreover, few people realize that in many, if not most, coal-mining operations about half of the coal in the ground is wasted.

Within recent years (1903-04) Willis, Blackwelder and Sargent, working under the Carnegie Institution, Washington, carried out an extensive geological reconnoissance in China proper. Their excellent work was published in three large volumes by the institution in 1907, but is held for sale by this "impecunious" organization at such high prices as to be beyond the reach of the average purse. The work of these geologists is, however, so meritorious that it will doubtless prove to be an immense help in the future to mining engineers engaged in the development of the country.

Geological Characteristics

Bailey Willis likens North China roughly to the eastern United States, and South China to the Western states. The coal fields of Shansi resemble those of Pennsylvania and the gold-bearing rocks of Chihli those of the Appalachian Mountains. The Sierra Nevada and the Coast Range he likens to the Tsin range of Shensi and perhaps also the rocks of Yunnan, Kweichow and Kwangsi. He states there is no one region that may be characterized as especially rich in minerals.†

The central areas of China proper appear to be composed chiefly of the upper Paleozoic rocks, Devonian and Carboniferous, and in the latter as well as in the younger Jurassic coal measures, we find the great coal beds which are certain to make China a tremendous factor in the economic history of the world. There has been so much idle talk in the newspapers on great fundamental conditions of this kind that one almost hesitates to refer to the subject, but nevertheless it is a fact which must be driven home and ever kept in mind, for it is as certain as anything can be that in the future the cheap fuel, cheap and efficient labor, and temperate climate, with the centers of trade and manufacture having free access to seaports throughout the entire year, present a combination of conditions of a most potential character. Add to this an abundance of fairly good iron ores, though rather lean as compared with American standards, the whole presents a field of possibility in this age of steel and cement the importance of which cannot possibly be overestimated. In Szechwan province there is also promise of oil and natural gas, but as yet I have not heard of any great gushers or naturally flowing wells having been tapped, although there is no reason to suppose they will not be in the future. The same geologic conditions which have made Pennsylvania the greatest of our industrial states are to be found abundantly throughout central China. It is needless to mention that coal, iron and oil are the very backbone of our great modern mining and manufacturing industries.

But China is not without many other mineral deposits. It is not my purpose now to go into details, but it may be accepted as a fact that practically everything of a mineral character has been found in some part of that great Empire. Probably, as elsewhere, many, if not most, of these deposits will not be of economic importance—at any rate not for years to come. In timber China is woefully poor. Her forests have been ruthlessly destroyed and not replaced. This, however, is a defect which time and care will rectify, for trees may be planted and forests grow to maturity in a period of time not much beyond the span of the average human life. But time in our human conception can never replace the coal burned and the metals consumed. Hence in a sense, China is younger than the United States, for its mineral resources are practically untouched, whereas we are rapidly depleting both forests and mines. We are, as a nation, something like 4850 years younger than China. These statements may seem fanciful; I admit they are decidedly general, but I fail to see how they may be well disputed. At any rate they afford substantial food for reflection, and it is worth while carrying them in mind.

The Unbalanced Population

There is also another side of this picture. China is over-populated, or at least its population is badly distributed, for until recently it had no railroads by which proper distribution could be accomplished. Moreover, many parts of the northern provinces near Mongolia are arid and can never be expected to support a large population. Irrigation and stream-flow regulation will no doubt do much to overcome this drawback.

Then again, the great plains of China to the south and north of the Shantung promontory are subject to disastrous floods from the Yellow River. This great stream carries out into the China Sea vast quantities of yellow silt from the *loess* or yellow-dust deposits of the northern provinces; and while its waters often bring destruction in one hand their burden of silt carries fertilization in the other, for this *loess* soil contains considerable calcareous and nitrogenous material which enriches the fields upon which it is deposited. It is manifest, therefore, that where this turbulent stream is confined within its banks by artificial means the river bed will rise by reason of the deposition of the silt upon it and the surrounding land will not be fertilized as when it is overflowed and the silt

*It is not generally known that in 1865 Richthofen made an examination of the Comstock lode for the Sutro Tunnel Co. The report was published for private circulation, hence copies are now scarce. Becker draws largely from it and speaks of the work in the highest terms. See "Geology of the Comstock Lode"—G. F. Becker, U. S. Geological Survey, 1882.

†Economic Geology, Vol. III, pp. 5 and 6.

deposited thereon. Evidently the control of the Yellow River will be one of the greatest and most difficult engineering problems in all China. Whether the Chinese themselves are able to cope with anything of the kind either financially or as a matter of engineering is doubtful. Besides the improvements of the Yellow River, there are a number of similar problems of lesser magnitude on smaller streams that will have to be taken in hand. Even now one large American engineering company is engaged in diking the Huai River in Kiangsu Province, and in draining Hangsu Lake, which is in fact part of the low-lying district or delta through which the Yellow River flowed before it changed its mouth in 1852 to where it now empties into the Gulf of Chihli, north of the Shantung Peninsula.

Engineering Opportunities in China

It must not be supposed for one moment that the outside world has been ignorant or indifferent to the great engineering opportunities in China. Since the days of Wharton Barker and Count Miskevitch, who, it is jokingly said, received a concession from Li Hung Chang which virtually gave them all the mineral resources of China, concession hunters have been haunting Peking and securing grants of one kind or another on absolutely scandalous terms by which the natural wealth of the country was practically given away. A few years after the Boxer troubles of 1900 a reaction set in and efforts were made by the Chinese government to get back some of these huge improvident concessions, and in one way or another these efforts appear to have met with considerable success. But there are some concessions, like that to the Peking syndicate, which continue to hold good and are of tremendous value. This particular concession as originally granted to this syndicate included pretty much all the coal in Shansi, which might be compared as approximately equal in value to all the coal, both anthracite and bituminous, in Pennsylvania. This syndicate also received considerable coal areas in Hunan Province and railroad grants of great value.

Realizing the serious mistakes that were made, the Chinese have been using every possible effort to recover what they have so thoughtlessly given away. As a result this reaction, and the very proper but perhaps over-zealous cry of "China for the Chinese," has brought about the enactment of mining laws for the country that are on the whole unwise, restrictive and destined to hamper rather than encourage development. It is evident these enactments have been inspired more by fear than by reason, and as a sensible people we may confidently look to the Chinese for such modifications as will meet any reasonable conditions which foreign capital must demand and receive before undertaking large mining investments in China.

China's future economic importance lies in the development of her coal, iron, cement and oil industries, and with her inexhaustible supply of cheap and good (as compared with India) labor, she is certain some day to be a most tremendous factor in the economic world. This statement in substance has been so often made it is almost trite, but nevertheless it is a prognostication that may not be successfully disputed.

⁂

Elementary Oxygen Imparts a Red Color to an alkaline solution of catechol and ferrous sulphate (C.Journ. Soc. Chem. Ind., Mar. 31, 1915). The reaction may be applied to the quantitative determination of oxygen in gaseous mixtures.

Alaskan Timber Reserve

The President has signed an order establishing a timber reserve, approximately 200 miles in length and from 5 to 10 miles in width, in Alaska to be known as "Alaskan Timber Reserve No. 1."

The reserved timber is upon public lands north of the Chugach National Forest, extending five miles in width along the northern shores of Knik Arm and Cook Inlet between the mouth of the Knik River on the east and the mouth of the Susitna River on the west, thence north five miles on each side of the Susitna River from its mouth on the south to the mouth of the Yentna River on the north. The reserve also embraces the timber on areas five miles in width on each side of the right-of-way of the main line of the proposed railroad through the Susitna Valley to Broad Pass, and similar areas on each side of the right-of-way of the proposed branch line extending into the Matanuska coal fields.

The purpose of the reservation is to prevent the timber needed for the construction of the Government railroad and its branches in Alaska from falling into the possession of individuals or corporations, in which event it would be necessary for the Government to purchase timber which it once owned. It is not the intention of the Government, however, to make any unnecessary restrictions which will tend to retard the development of the Territory of Alaska along the line of the railroad or its branches, and in the withdrawal order the interests of the public have been conserved in every way possible. Only the timber on the land, not the land itself, has been reserved. The land is still subject to location, settlement or entry under the public land laws, and it is provided within the withdrawal order that the Secretary of the Interior may permit settlers in the locality to obtain such timber as they require.

⁂

Russia's Prohibited Exports

By a decree of May 17, all previous prohibitions of and restrictions on the exportation of goods from Russia have been codified. The prohibitions cover the exportations by all frontiers of copper and brass in the form of metal, scrap or manufactures; the exportation by the land frontiers of European Russia and by ports of the Baltic, White and Black Seas, and the Sea of Azov, of coal and coke, pitch, iron ore, manganese ore, naphtha and naphtha waste, benzine, petrol, ligroine, kerosene and other illuminating naphtha oils, spirit, rubber in all forms including manufactures thereof, wire, caps, fuses, saltpeter, nitric and sulphuric acids, and automobiles. The exportation of steel and lead is prohibited by all land and sea frontiers of European Russia.

⁂

Magadi Soda Co.

At the recent meeting of the Magadi Soda Co., Ltd., in London, it was announced that the work at Magadi had practically come to a standstill owing to the war. The railway line and water-works were commandeered by the Government and the employees of the company volunteered and formed a defense force for the colony under the command of the local manager, Major Symonds. The railway line, which extends through from the coast to the lakes, is still under governmental control.

Editorials

American Zinc Smelting Capacity

In the JOURNAL of March 6, 1915, we estimated that the United States had capacity—first-class and second-class—for the production of about 517,000 tons of spelter per annum at the maximum, but pointed out that that figure ought practically to be discounted for several reasons which need not be repeated. A further necessity for discounting that total is the practice, that has developed among several smelters, of redistilling ordinary spelter for the sake of making a high-class intermediate. This not only involves a double use of capacity, but also entails a considerable loss of spelter in the process, reducing the final output of metal by just so much. On the other hand our estimate did not include the dross- and junk-smelting capacity, which without doubt is in excess of 25,000 tons of spelter per annum, reckoning only the commercial concerns, i.e., excluding all which resmelt their own by-products. Some of these concerns have lately been engaged in producing superior grades of spelter. Making all allowances therefore, it is probable that the listed zinc-smelting capacity at the beginning of 1915 was at least equal to the production of 500,000 tons of spelter per annum.

That list enumerated the smelteries of the United States as "active," "operated irregularly," "inactive" and "new." Since that time every plant on the list has been put into operation, while old plants stricken from the list many years ago, some of them idle since about 1901, have been restored to use. Such are one of the old works at Pittsburgh, Kan., and the old plant at Bruce, Kan., while it is now said that the old plant at Nevada, Mo., is to be repaired and put into commission. All of these are small plants and do not add largely to the smelting capacity of the United States. More important are the extensions of going works that are being made. Thus five furnaces are being added at Caney, a large number at Sand Springs, while at Langeloth new furnaces have been put into commission as rapidly as possible. Additions are being made or are contemplated at other works.

We are now coming to the time when new plants are being projected, the construction having been actually begun in one case. George E. Nicholson is building a four-block plant near Tulsa, and a Joplin company is said to be contemplating a new plant at Pittsburgh, Kan.

It is now reported that the new zinc smeltery of the U. S. Steel Corporation at Donora, Penn., will have a capacity for the production of about 40,000 tons of spelter per annum. This implies an ore-smelting capacity of about 100,000 tons, which will make it by far the largest zinc smeltery in the United States. The works are to be erected on a site adjoining one of the large galvanizing plants of the Steel Corporation. The purpose of the Steel Corporation in erecting this plant is to take one more step in its policy of providing its own raw materials.

Apart from the plans of the Steel Corporation, which for reasons of its own are well-founded, it is evident that the willingness of adventurers to take chances in the erection of new works indicates a belief that high prices for spelter and large smelting margins will prevail for a long time. However, we surmise that all records for speed in zinc-smelting construction will be broken in the works that George E. Nicholson is now building in Oklahoma.

It is evident that we are already witnessing the provision of a very considerable increase of smelting capacity with the probability that more will follow. This will of course gradually ameliorate the tenseness in the zinc situation even if nothing else does so.

Zinc Ore and Spelter

The abnormal conditions existing in the zinc industry of late, and at present, have produced extraordinary variations with respect to the value of zinc ore, and a good deal of the controversy respecting the latter is due, no doubt, to misunderstanding of the terms of buying and selling raw material.

Zinc ores are sold in three principal ways—on sliding-scale contracts, on flat contracts, and by bids and offers in the open market.

Sliding-scale contracts are based upon the price for spelter. We have lately witnessed circumstances wherein ore coming in under sliding-scale contracts was paid for on the basis of 25c. for spelter, while the smelters were delivering spelter at 8 to 10c. per lb., which had been sold several months previous. The time will come of course when the opposite condition will prevail—that is, smelters may be taking in ore on the basis of 8 to 10c. for spelter and receiving upward of 20c. upon deliveries that were contracted for during May.

The selling of ore upon a flat price is a very simple matter. For example, a mine operator may in December agree to sell his output for the next six months at so much per ton, and be done with it. In this case fluctuations in the metal markets are of no concern to him, except that he is likely to feel good if it turns out that spelter averages less than what he figured—and inevitably he will feel sore if it turns out the other way.

The third way of selling zinc ore, the way that prevails especially in the Joplin market, is precisely analogous to the selling of any commodity, day by day or week by week, by offering it in a public market. Buyers bid what they think it worth to them, and sellers refuse to accept their bids if they think them too low.

Last spring the price for ore in the open market was excessively low. There were two chief reasons. The supply of ore offered under contracts was bountiful, and smelters, unable to sell spelter ahead with the freedom they desired, were reluctant to take chances on buying too much ore. Later the ability of the smelters to sell their spelter ahead changed radically, which made it

safe for them to buy ore against their contracts, and then the price for ore in the open market rose.

In considering the relations between zinc ore and spelter there are several things that it is needful to bear in mind. Some of these are the following:

A smelter must carry in stock a supply sufficient to run his works from one to three months. Consequently it is to be reckoned that such a time has to elapse before the zinc of incoming ore is rendered marketable as spelter.

The bulk of the blende of the Joplin district and Wisconsin is taken by the smelters who make sulphuric acid, especially the smelters of Illinois, who prefer those kinds and whose competition years ago practically drove the other smelters out of the Joplin market.

Nearly all the ore from the regions west of the Rocky Mountains is marketed according to sliding-scale contracts, and the old system, which still prevails in the Joplin market, is of far less importance than it used to be, the total ore tonnage of Missouri, Kansas and Oklahoma in 1914 being only about one-third of the total receipts of the smelters; but on account of its superior grade this ore probably accounted for nearly three-eighths of the production of spelter in that year.

*

The Rise and Fall of Lead

The consensus of opinion is that the recent rise in lead, or the spectacular part of it at least, was engineered in Wall Street. The evidence on this point is considerable. The early stages of the rise from the level of 4.20c. were economically well founded. A shrewd, powerful and well-informed group of speculators then perceived and seized the opportunity to conduct a movement. The buying on the way up was not confined to them, however. Consumers and ammunition manufacturers were overcome by a panicky feeling, having the previous events in spelter fresh in mind, and entered into some very large contracts for deliveries far ahead at high prices. This business was done chiefly around 6c. Of course the bulk of the lead consumers were unaffected, their supplies being provided for by long-time contracts with settlements on quotations. Although they might have to pay more for their June lead, they were not in any doubt about getting it. A very large proportion of the lead business is done in this way. The quantity of free lead being correspondingly small, the recent speculative operations were the more easily conducted.

During the excitement the leading interest—the American Smelting & Refining Co.—preserved its poise admirably, maintaining its price of 7c. even while outside lead was realizing 8c. On the other hand it inflamed the situation by refusing to deviate from its policy of selling only for shipment within 30 days and moreover declining to do business with all comers, giving the preference to its regular customers. These procedures were unexceptionable; but they naturally excited crazy buyers, who tried and failed to obtain lead in the principal quarter, and forced them to sellers who had been standing aloof, waiting for just such an event.

The collapse came when speculators undertook to realize and found that they had been played with. Just as they had bid up the market against themselves, they depressed it. The A. S. & R. Co. completely lost control of the market on the way up and equally so on the way down. In the end the only course for it and other producers was to withdraw and wait for liquidation to exhaust itself, for no matter how low their price might be put the traders would go ½c. lower so long as they had any lead remaining to be sold.

*

Wet Concentration, Flotation and Leaching Recoveries

The average copper recovery of the five large wet concentrating mills of the porphyry coppers now in operation in this country is 68.03%. The average recovery by use of the flotation process is generally higher than this. At the 50-ton experimental unit of the Cuba Copper Co. an extraction of 85% was made. At the National mill at Mullan, Ida., with a capacity of 500 tons per day, a total extraction of 85% was made, 30% being obtained by the tables and 55% by flotation units. The Butte & Superior mill using flotation is making 88.03% recovery. The Braden, which is now treating between 3000 and 4500 tons per day, makes a recovery of 75% by the flotation process, and it is officially stated that this figure may be considered a very conservative statement of results accomplished. At the Inspiration, in Arizona, the experimental mill which treated 76,000 tons of ore gave an average recovery of 86.7%, and at times as high as 90.3%. It was on the basis of results accomplished in this experimental mill that the Inspiration is now building its 15,000-ton per day flotation plant, one-half of which is nearly ready for operation; the other half it is expected will be in operation by the end of this year.

Based on a large amount of experimental work, a leaching plant said to be of 4000 tons capacity is being designed for the New Cornelia in Arizona. The elaborate tests conducted by Mr. Croasdale demonstrated that a recovery of between 80% and 85% was obtainable, depending upon the fineness of crushing and the length of time of leaching.

These figures are not given as a comparison to indicate that a superior process has at last arrived to totally displace "the honorable" wet concentration, but only to answer a question about relative results which frequently arises. The fields for application of these processes overlap to a certain extent but the processes are not interchangeable and none is universally applicable.

*

Why Chemical Dealers Don't Answer Inquiries

We are constantly receiving complaints that letters of inquiry to various manufacturers of alloys and chemicals do not bring any replies. This is perhaps explained by the statement of a prominent official of one of these companies that at the outbreak of the war they were simply swamped with inquiries regarding rare chemicals and rare alloys. After spending a great deal of time replying to these letters, they looked up a few of the inquiries and became convinced that they were simply dictated by German agents who wished to find out what this company was going to do in the matter of supplying various materials which usually came in from Germany. Since that time, he said, they had answered only letters from persons who were known to them or who gave them unimpeachable references.

BY THE WAY

A U. S. Geological Survey Bulletin gives a list of well-known rivers and the amount of organic matter contained. The Nile has 10.36% ; the Hudson 11.12% ; the Delaware 16% ; the Uruguay 59.9% organic matter—we have eaten many vegetable soups that didn't come up to the latter.

⁂

A shoveler in one of the Joplin zinc mines who had seen in the movies how the gold miners bought what they needed with gold nuggets, last week laid a small chunk of zinc ore on a bar counter and called for a beer. The bartender served the drink to him and laid down 20c. in change and, of course, the crowd laughed and cheered. Such, says the *Wall Street Journal*, is the spirit of the Joplin zinc boom, with crude zinc ore now worth 7c. a pound which is about 50% higher than the refined product spelter has averaged for many years.

⁂

Louis H. R. von Ruecau, a mining engineer, who operates the Cuale mine in the State of Jalisco, Mexico, when not dodging or stopping bullets or visiting in the United States, tells of an amusing experience which threatened to put a permanent end to his activities. While visiting a Mexican friend in the city of Tlaxcala a local home-made 7-mm. revolution broke out. Louis heard that something had started; but although he has occasionally been a target for frivolous Mexicans, he did not attach very much importance to the rumor and enjoyed his customary strolls about the town. One evening while pausing to light a cigar he felt a cold circle of steel pressed against the back of his neck. Casually glancing over his shoulder, he gently inquired what might be the trouble. The sandaled patriot behind the gun gruffly hiccoughed: "I am going to kill you, because you are a —— —— foreigner." "That is foolish and unnecessary," replied the prospective victim. "But that is a beautiful rifle you have. Is it not a new one?" "Ah, si, Señor. I just received it today. Here, take it and examine it and tell me if you do not think it is a very fine rifle." Von Ruecau took the rifle, looked it over carefully and handed it back, offering a fine cigar with the other hand. The peon accepted his rifle and the gift; then he took off his hat and bowed politely, saying: "Many thanks, sir; I wish you good-night."

⁂

Because the question of a general amalgamation of Rand gold mines has been so frequently discussed in recent months, this subject was touched upon by Chairman Lionel Phillips at the recent annual meeting in London of the Central Mining & Investment Corporation, which has extensive interests in this field. He said: "A good deal of discussion has taken place in recent times upon the subject of a general amalgamation of the gold mines. Looked at purely as an economic proposition, I have no hesitation in saying that considerable economies could be effected if the control of the mines were vested in a single body of capable men, and the interests of all shareholders were rendered identical instead of continuing the present system of various and, in some cases, competing interests. I must not go fully into so complex a subject today, but I venture to say that, under existing conditions, general amalgamation is neither desirable nor practicable. In the first place, we know by our more limited experience of uniting mines that it takes a considerable time and expenditure of capital before full benefits can be manifested. In the second place we know that, although an amalgamation of mines might contribute to the ultimate welfare of the South African Government and people, it would involve considerable hardship to the Witwatersrand community in the first instance, and the political effect of such a step cannot be disregarded. I am therefore of opinion that we should at present, anyhow, dismiss from our minds so ambitious a scheme as that of general amalgamation."

⁂

Ross-Burrage Hearing to be Sept. 13

The suit of Louis Ross against Albert C. Burrage, vice-president of the Chile Copper Co., to recover 10% of the profits secured by Burrage in the flotation of that company, has by consent of both sides been put down for final hearing on Sept. 13, according to the *Boston News Bureau*. Ross claims to have been the original discoverer and to have secured options for Burrage, working on salary and commission under written agreement. These options were transferred by Burrage to the Chile Exploration Co., all of the stock of which rests in the treasury of the Chile Copper Co.

⁂

Changes in British Prohibited Exports

An Order in Council has been issued making a number of amendments in and additions to the British list of prohibited exports. The following are the alterations in the section covering the iron, steel and allied industries, says the *Iron and Coal Trade Review:*

That the heading, "Zinc and iron ore (including zinc ashes, spelter, spelter dross, and zinc sheets)," in the list of goods the exportation of which is prohibited to all destinations abroad other than British possessions and protectorates, should be deleted, and there be substituted therefor the heading, "Zinc (including zinc ashes, spelter, spelter dross, and zinc sheets)," in the list of goods the exportation of which is prohibited to all destinations, and the heading, "Zinc ore," in the list of goods the exportation of which is prohibited to all destinations abroad other than British possessions and protectorates.

That the following articles should be added to the list of goods the exportation of which is prohibited to all destinations abroad other than British possessions and protectorates:

Chemicals, drugs, medicinal and pharmaceutical preparations: Hydrochloric acid; oxides and salts of nickel; oxides and salts of tungsten.

Metals and ores, the following, namely: Wolframite; minerals and vegetable wax; tungsten filaments for electric lamps.

That the following articles should be added to the list of goods the exportation of which is prohibited to all foreign ports in Europe and on the Mediterranean and Black Seas, other than those of France, Russia (except Baltic ports), Spain and Portugal:

Chemicals, drugs, etc.: arsenic and its compounds.

PERSONALS

H. A. Morrison is investigating a placer proposition near Weaverville, California.

H. J. Wolf, of Denver, examined mining property in Gilpin County, Colorado, recently.

Benj. H. Case has returned to Asheville, N. C., after several months' professional work at Mineral, Virginia.

Alexander Stanley Elmore, who has been visiting in this country for several months, returned to London on June 26.

George H. Garrey was in New York for a few days last week and has now gone to San Bernadino County, California.

R. D. Fetherstonhaugh, of Vancouver, B. C., and party have gone to investigate mining prospects on the Peace River and at Fond du Lac.

J. Norman Bulkley, of New York, has been appointed consulting mechanical and electrical engineer to the Canadian Mining & Finance Co., Ltd., of Montreal.

Arthur J. Hoskin, of Denver, has been for the past two weeks in the Tincup district, Colo., for the Tincup Gold Dredging Co., drilling and examining placer ground.

Thomas H. Kenvin recently with the Indiana Steel Co. at Gary, Ind., left last week for India to take a position as superintendent of the steel department of the Tata Iron & Steel Co. at Sakchi, Bengal.

Silvio DeVescovi lately engineer with the Societe Francaise des Mines de Cuivre Collahuasi-La Grande, in Collahuasi, Antofagasta, Chile, is now enrolled in the Italian army and has gone to the front.

L. D. Cooper of the engineering staff of the E. J. Longyear Co., Minneapolis, Minn., sailed last week with a crew of 60 miners for Norway, to sink a shaft for the Orkla Mining Co. at Lökken, near Trondhjem.

Robert L. Sackett, late of Purdue University, has been appointed Dean of the Engineering School of Pennsylvania State College. He succeeds John Price Jackson, who is now labor commissioner of Pennsylvania.

W. C. Tharp, recently with the Metallurgical Testing Laboratory of Pittsburgh, has been appointed manager in Pittsburgh for the Hoskins Manufacturing Co., of Detroit, makers of electric furnaces and pyrometers.

David A. Thomas, for many years a well known coal mine owner and operator in Wales, has been appointed purchasing agent for Great Britain in the United States and Canada and will have offices in Ottawa and New York.

The well known firm of D. R. Hanna & Co., Cleveland, Ohio, prominent shippers and miners of iron ore and coal has been reorganized. D. R. Hanna has retired, L. C. Hanna and H. M. Hanna, Sr., have associated themselves with the remaining partners, R. L. Ireland, M. Andrews and H. M. Hanna, Jr. L. C. Hanna was formerly head of the firm, retired some years ago and now returns.

Dr. Arthur A. Noyes, of the Massachusetts Institute of Technology, is to become a member of the faculty of the Throop College of Technology, Pasadena, Calif., for a portion of the coming academic year, and for one-half of the time in succeeding years, beginning with 1916-17, this arrangement having been made possible by a gift of $10,000 for the equipment of a physical chemistry laboratory, and the endowment of this laboratory in a sum yielding $10,000 annually for its support.

OBITUARY

Frank S. Castello, President of the Mary McKinney Mining Co., Colorado Springs, died June 18 at Los Angeles, Calif., where he had gone for his health. He was interested in several other companies in the Cripple Creek district.

Among those reported killed in the Mexican troubles are Stephen A. Parmenter, an engineer who is reported to have been killed at El Favor mine in Jalisco, June 22, and Robert Camp, formerly of Denver, who was reported by telegraph killed at Monterey.

A dispatch from Washington, June 19, says: "Gilbert Trambl, of Oklahoma City, superintendent of an iron mine, was killed while interfering in a private quarrel near Charcas, Mexico, on Wednesday. A dispatch to the State Department from Consul Bonney, at San Luis Potosi, today announced three arrests had been made.

John A. Finch, for many years a prominent mining man in the northwest and one of the pioneers of the Cœur d' Alene, died suddenly at Hayden Lake, Idaho, June 20. He was 61 years old and had been engaged in mining in Idaho, Montana and Washington for the greater part of his active life.

Henry C. Bolsinger died in Denver, June 21, after a long illness. He was 59 years old and for over 40 years had been engaged in mining in Colorado, having been at Leadville and Cripple Creek as well as at Central City, which was his home and headquarters for a number of years. He represented Gilpin County in the Colorado legislature for several years. He was also in Mexico for a time. He had a remarkable memory and a wide knowledge of mining property and was credited by his friends with knowing the history of practically every mine in Colorado for the past 40 years.

Scott Eldridge, mining engineer of Kerr Lake mine, Cobalt, Ont., and W. B. Foote, a capitalist of Geneva, N. Y., were instantly killed on June 25th by a blast at the mine. Mr. Foote who was about 45 years of age, had been in Cobalt for two or three days looking after his investments. He was being shown the Kerr Lake mine by the engineer, and they were in the stope at the 140-ft. level when the blast went off at the regular time at the 250-ft. level, and coming up the stopes killed both of them. Mr. Eldridge was about 25 years of age and leaves relatives in Philadelphia.

Thomas D. West died in Cleveland, Ohio, June 18 from injuries received by being struck by an automobile. He was 64 years old. He was born in England, but came to this country when a boy and when 12 years old, began work at the foundry of the Portland Locomotive Co., Portland, Maine. After mastering the foundry business, he organized a company at Sharpsville, Penn., which is now known as the Valley Mold and Ingot Co., makers of ingot molds. In 1907, he organized the West Steel Casting Co., at Cleveland, Ohio, of which he had since been head. Mr. West devoted much time and labor to the elevation of the foundry business and to the writing of text books on foundry practice and the metallurgy of cast iron. He was much interested in the American Foundrymens' Association, of which he was always an active member and of which he was president for several years. He established the use of standardized drillings for the checking of pig iron analyses as well as many other improvements. In the recent years, he was very much interested in the movement for the prevention of accidents and for greater safety in industrial employments. He was a member of the American Society of Mechanical Engineers, the American Society for Testing Materials and several other mechanical and scientific societies. He leaves a widow, a daughter and two sons.

Charles L. Gilpin, who for many years was one of the most widely known men in the sheet trade, died at a hospital near Philadelphia, June 7, aged 88 years. He was born at Wilmington, Del., and after receiving his education in that city moved to St. Louis in 1845, where he engaged in the iron and steel business. During the Civil War he was connected with the quartermaster's department of the army. After the war he was for many years associated with Alan Wood & Co., now the Alan Wood Iron & Steel Co., Philadelphia, and subsequently with W. D. Wood & Co., Ltd., Pittsburgh, and the successor, the W. Dewees Wood Co. He was a relative of W. Dewees Wood, who sent Mr. Gilpin to Russia to investigate the manufacture of Russia sheet iron, and to ascertain how to reproduce in this country the beautifully planished surface of the sheets which were then celebrated throughout the world for their rust-resisting quality. He was successful in his investigation, his genial personality contributing largely to this result, and the process thus brought to this country established the reputation of the firm whose plant was finally merged with other properties into the American Sheet Steel Co., afterward becoming part of the United States Steel Corporation. He was exceptionally well informed on the steel business, especially the sheet branch, and was an authority on tariff legislation. He leaves his widow, one son and two daughters.

INDUSTRIAL NEWS

K. E. Kersten has been appointed branch manager of the Boston Belting Co., 172 West Randolph St., Chicago, Ill.

The Terry Steam Turbine Co. announces the appointment of Joseph Battles as District Sales Manager for Denver, covering the states of New Mexico, Colorado, Wyoming and the western part of Nebraska. His address is 326 First National Bank Bldg., Denver, Colo.

Editorial Correspondence

SAN FRANCISCO—June 23

Corporation Tax in California for 1915 amounts to $15,036,798, as against $13,609,633 in 1914. The largest corporation tax payers are the railroads, which will pay an aggregate of $6,588,284; oil wells will pay $410,034; power companies $122,761, and mines $69,870.

Gold-Dredge Construction for the last year or so has not been so active as in recent former years and there has been a good deal of talk about the gold-dredging fields being exhausted. There have been a number of things combining to retard advancement of gold dredging for the last two years. The present aspect of the industry is much brighter and contracts are being let for dredge construction to be completed within the next two years that will total approximately $750,000. As to the exhaustion of dredging fields there is no solid basis for such reports. It has been the policy of all large mining investors who have their money placed profitably to play a waiting game with the owners of mining ground, whether placer or quartz. In various instances large areas have been examined by dredging companies and turned down for different reasons, that prospecting did not prove high values, or the price was too high, or the terms not satisfactory. So long as dredges can be operated in rich gravel deposits there is not much hope of low-grade properties being successfully exploited. But the rich placer grounds are being exhausted and dredge operators must content themselves with lower yield per cubic yard. The demand for gold is sufficient incentive to attract investors to ground that will pay a fair margin on the investment in dredge construction. The recent contracts for new dredges and contemplated construction include the Yuba Consolidated Gold Fields at Hammonton and the Marysville Gold Dredging Co. at Marigold, the Natomas Consolidated at Natoma, in California, and the Powder River Gold Dredging Co. near Baker City, Oregon. Yuba Consolidated contemplates the construction of an all-steel dredge to be known as Yuba No. 15. It will be of the same design as Yuba No. 14, which was put in commission in December, 1914. No. 14 is at present the largest all-steel gold dredge in the world and is equipped with 16-cu.ft. buckets. No. 15 will be a larger boat and will probably be an improvement in some respects upon the other dredge. This dredge will be built by the Yuba Construction Co. at Marysville. The Marigold dredge will be built by the Union Iron Works and will be similar to Yuba No. 14 and equipped with 16-cu.ft. buckets. Guggenheim interests on Yuba River, north of the Yuba Consolidated, also contemplate construction of one or more dredges; though their plans have not yet been made public. This land has formerly been turned down by other investors, but it is safe to say that there is a possible profit in sight or the Guggenheims would never have taken over the land. Natoma No. 4 dredge which operates in the Natomas field on American River will be rebuilt after a new design which will provide for the placing of the tailing so that the gravel will be evenly distributed for the soil on top. In other words the dredged land will be reclaimed for agricultural purposes. There is a large area of agricultural ground within the dredging field at Natoma and there has been in the past a great hue and cry about the destruction of valuable agricultural land by the gold dredges. While it might have been possible in the beginning to reclaim all these lands as the dredging was being done, the financial results might not have enabled the Natomas, or any other operators, to operate at a profit sufficient to guarantee large investment. The Powder River Gold Dredging Co. in Oregon has now in course of construction a 7½-cu.ft. bucket-elevator dredge of the California type, designed and built by the Yuba Construction Co. This dredge will dig 30 ft. below the water line, which is sufficient depth for its ground. This will not be an all-steel dredge, but will have a wooden hull which will be entirely fireproof. The experience of the Yuba Construction Co. in dredge construction will guarantee notable advancement in the construction of wooden hulls. It is reported that another dredge is contemplated in the Baker City region by the owners of the I. L. Borden bridge (formerly the Isabella) at Jenny Lind, Calif. Placer ground is being examined in Shasta and Trinity Counties with fair prospects of dredges being installed and it is not unlikely that before the end of the present year the installation of new dredges will be undertaken, not only in these counties but in other parts of California. It is not likely that there will be demand for more of the large all-steel dredges, but there is opportunity for installation of the smaller size dredges, and there is no good reason why such new construction should not be entirely of steel and patterned after the smaller boats recently completed for the Yuba Consolidated by the Yuba Construction Co. Gold dredging in California is by no means on its last legs.

BUTTE—June 24

Butte Now Has Three Miners' Unions, but they are not very formidable and are not likely to become so. When the old Butte Miners Union surrendered its Western Federation charter and seal it revived itself as the Butte Miners' Union, a corporation, and solicited members among the miners who are opposed to Moyer and his federation crowd. The union has been going it alone nearly two weeks and has succeeded in getting a membership of about 40. Moyer's federation agents have been working to get members back into the fold for six weeks or more and are now operating under the name and charter which the old union surrendered, but in six weeks they have obtained only about 200 members, and that seems to be about the limit of the federation sympathizers. Then there is the original rebel organization of I. W. W.'s, the Butte Mine Workers' union, which still maintains an organization through a few officers, but has no members. There are more than 12,000 miners working in the Butte district again, and the results of the efforts to organize unions indicate that the men who work with their hands are satisfied to stay on the outside and that they have no particular sympathy with the men who work with their jaws only. The miners are getting their $4 a day, and they have neither union nor contract to enforce the payment, but they find that the employing companies are a pretty decent lot of corporations and will do right if permitted to do it.

DENVER—June 25

Golden Cycle Mining & Reduction Co. will hereafter declare dividends of 2c. per share on the 10th of each month with strong probability of occasional special dividends to "take up the slack."

Midland Oil and Gas Company has been incorporated for $100,000, by Denver men to explore, by drilling, 160-acre tract a few miles northeast of the city. Another company, the Mid-Colorado, has drilled down 1800 ft. on another property in same locality and is still drilling. For years, geologists have believed that oil and gas exist in these measures although probably at considerable depth.

Purchase of Stratton's Independence Mine, Victor, by the Portland Gold Mining Co. has increased the latter's area by 250 acres. As viewed by a man on the outside, one strong feature in this consolidation is the opportunity afforded to now handle, by gravity, the tremendous dumps about the lower Portland shaft into the Independence mill for cyanidation. While the Portland has a magnificent mill, it is on top of Battle mountain convenient to the dumps at the upper shaft. Material from the lower dumps can be delivered to this mill only at considerable expense for transportation. The Portland mine proper is in splendid condition for ore production. Officials are reticent about plans.

SEATTLE—June 22

The Most Important Mining Deal completed in Fairbanks in the last several months was consumated by the payment of $20,000 for the Midway Association group of claims owned by E. A. Suter, P. C. Charles and L. B. Clough, by Jack Leach to be operated on a lease. Mr. Leach will start work July 1. The property has never been considered very highly and has been held by the present owners for more than 10 years, with little development work, but recently the Sjolseth brothers operating on the upper portion of the claim struck pay that will run approximately $2 to the foot. The gold is coarse and is pronounced by miners to be "paystreak" gold.

Operators Are Jubilant here over the bonding of the Hermann-Eaton property to the Alaska-Gastineau Mining Co., of Juneau, and feel that it marks the advent of other big operators into the district. The property was located three years ago about 1½ miles from tidewater at the head of Beetles Bay, Port Wells. It consists of four claims, lying

at an elevation of 700 ft. The vein is exposed for 300 ft. and is a high-grade contact vein carrying free gold, lead and iron sulphides, and silver. There is an incline shaft 112 ft. in the ore. The new owners will sink to the 200-ft. level at once. By running a tunnel 650 ft. long and building a dam 10 ft. high and 30 ft. long, sufficient power to operate a 150-hp. Pelton wheel will be developed.

Ruby is Better Than Expectations according to the latest cleanups from that creek which show that early work has netted considerably more so far this year than before, and it is expected that this creek will more than double its 1914 output. Selch, Deitz & Walker during the winter expected the cleanup of their dump would net about $80,000 and with only half the dump sluiced the returns are better than $90,000. Alex Larson has found dirt on Long Creek that runs $7 to the foot. This ground is now being worked extensively. Ruby Creek did not suffer, as most of the creeks this spring, on account of the thaws and was remarkably free from overabundance of water which retarded work on so many creeks. This trouble is now over and all the creeks of the district are working overtime to make up for what was lost. This is true of the Hot Springs district which showed so well last year. At Tofty, Cleveland & Howell have the largest plant that is now in operation and the output for the year will be greater than last. Bock has commenced operations on Woodchopper Creek. Joe Eglar is working a large plant with several others and expects to take out a large yield this summer. Good cleanups have been made on Cleary Creek. John Parquette, in making a cleanup of No. 4 Below Cleary, found that his dump, which was taken out with a windlass in a month, contained $1957. He was prevented from doing work most of the winter on account of water. The same trouble was encountered by other operators on this ground, most of them are taking in or will take in shortly, boilers and mining outfits to cope with the situation.

FAIRBANKS, ALASKA—May 29

Fairbanks Production—The First National Bank of this city has prepared an estimate of the output of this region for the coming season. It looks for a total placer production of $3,150,000 with Cleary and Sullivan creeks as the largest producers. In addition, it estimates an output of $600,000 from hard-rock mines.

Antimony—E. L. Scafford, of Chatham creek has 200 tons of antimony ore on the dock, ready for shipment on the first boat via St. Michael. This ore will go about 60% antimony. The continued rise in the price of this metal has revived interest in the hard-rock prospects of the Kantishna country. Outcrops of antimony seem to be widely distributed in that region, which is about 100 miles west of here. Transportation to and from that district is very difficult as yet.

HIBBING, MINN.—June 26

The Largest Shipper on the Mesabi Range as usual is the Oliver Co. Ore is going forward at a rapid rate from all of the company's mines on the range, as well as on the other ranges. The independents are working most of their pit mines, but few of the independent underground mines are mining ore. The M. A. Hanna Co. is not turning a wheel on the entire Mesabi range. Many of the smaller operators maintain that they cannot make money by operating their underground mines at present.

DULUTH—June 25

Refusal to Pay Taxes by the Mining Companies owning property in the Village of Hibbing, on the Mesabi range, will place their case before the courts. The assessed value of the village is $84,000,000, and as the companies possess 86 per cent. of the property, the community will derive little money from the remainder of the taxpayers with which to pay running expenses. The companies have decided that the school districts shall not suffer from a lack of funds and have agreed to finance them if necessary. The action was taken on the part of the mine owners because of the extravagant use of money by the village authorities during recent years, mentioned in these columns Apr. 3. By refusing to pay their taxes the companies are placing themselves subject to a charge of 10% additional, which they are willing to risk to bring about a readjustment of existing conditions. At the last session of the Minnesota state legislature an effort was made to pass a bill limiting the per capita tax of towns and villages of the state to $25, but the bill failed in the house after passing in the senate by a large majority. The companies that have refused to pay are the Oliver Iron Mining Co., Mahoning Ore Co., Shenango Furnace Co., Jones & Laughlin Co., Inter-State Iron Co., Pickands, Mather & Co., Republic Iron & Steel Co., Rogers-Brown Co., Great Northern Ore Co., Sargent Land Co., and Northwestern Improvement Co.

LORDSBURG, N. M.—June 24

Sodium-Nitrate Deposits in Grant County are coming into prominence and are attracting the attention of those interested in the products of the mineral. The deposits were first discovered in 1913 and little attention was paid to them until the fall of 1914 when active prospecting began and large areas of mineral bearing ground were located. The nitrates are found on the western slope of the Peloncillo Mountains on the eastern side of the San Simon Valley near the town of Rodeo, N. M. The outcroppings can be traced for a distance of nearly 50 miles north and south with a width of from one to four miles. At Rodeo the outcroppings form the yellow cliffs fringing the eastern side of the San Simon Valley. Until recently little work, aside from the necessary location requirements had been done. On one of the best claims the deposits lie at an angle of about 45 deg. with a footwall of porphyry and a hanging wall of quartzite. At one place the body shows a thickness of over 100 ft. The nitrates are disseminated through the rock and where cavities occur in the formation, collect into nodules of nearly pure sodium nitrate. The deposits are favorably situated as regards railroad transportation, being a short distance from the El Paso & Southwestern tracks. Water is plentiful and all conditions are indicative of economical operation. The U. S. Geological Survey has not yet examined the Rodeo deposits of sodium nitrates but has expressed its interest. Thus far no potash or nitrate withdrawals have been made either in New Mexico or Arizona. The deposits are coming into prominence and are being examined by engineers from various parts of the United States.

WILLCOX, ARIZ.—June 25

The Mascot & Western R.R., which connects the mines of the Mascot Copper Co. with the Southern Pacific at Willcox, Ariz., was completed June 15 and a celebration in honor of the occasion was attended by about 4000 people, many of whom were shareholders of the Mascot Copper Co. The construction of this road was commenced the latter part of January, this year. Shareholders from the East and West came in special trains and upon arrival at Willcox were met by the mayor of the town and a delegation of business men, who with the Willcox band gave the incoming visitors a royal welcome and sent them over the last lap of their journey on the Mascot & Western to Mascot. Upon arrival there they were met by T. N. McCauley, president of the Mascot Copper Co., and the Sixth Field Artillery Band. Following speeches by Mr. McCauley, H. A. Morgan the mayor of Willcox, James G. McNary, vice-president of the First National Bank of El Paso Mayor Frank K. Mott of Oakland, Calif., Hon. John A. Street chief counsel for the company and Judge John M. Raymond, of Aurora, Ill., the crowds were directed to the railroad tracks near the depot where President McCauley drove the last spike which officially completed the railroad. A large barbecue was then served, for which about a dozen fat beeves had been prepared.

The Building of This Railroad means much to the Dos Cabezas mining district where rich mineral ground has been known to exist for years. While the railroad has been built exclusively by the Mascot Copper Co. for the transportation of its ores to the smelters, it will have as a feeder the entire Dos Cabezas district. Already considerable activity has been apparent in the district other than that of the Mascot company since the new road was started. Transportation is all that has been lacking to make this district occupy a prominent place among the mining camps of northern Cochise County, Arizona. Several years ago the Mascot company commenced the development of its claims embracing about 800 acres of highly mineralized ground in the heart of the Dos Cabezas district. The main development has been carried on through a tunnel known as the Consolidated tunnel on the western portion of the property. By means of this tunnel the ore has been developed and blocked out for a depth of about 700 ft. below the surface croppings. The tonnage is estimated to be about 1,000,000 tons of merchantable ore. The railroad, just completed, cost $300,000. Its length is 15 miles and although the last four miles traverse a mountainous country, the steepest grade is not more than 3%. At the same time the construction of the railroad was commenced an aërial tramway, 10,000 ft. in length, with a capacity of 1000 tons per day, reaching from the mines to the unloading bins at the new town of Mascot, was also begun. This was rushed to completion simultaneously with the railroad and cost about $20,000 per mile. At the close of the ceremonies June 15, the first train of ore left the camp for the smeltery at Douglas.

NEW YORK CITY—June 30

Miami Copper Co. has increased its dividend to 75c. per share, payable Aug. 15. This increase was entirely unexpected.

The Mining News

ALASKA

GRANBY (Valdez)—Outside construction to be finished in about a month, when Midas mine will start operating.

ALASKA INDUSTRIAL (Ketchikan)—Aërial tram being repaired. Expect to start shipping copper at once. Charles E. Sulzer is manager.

ALASKA FREE GOLD (Willow Creek, Knik)—W. E. Martin plans installation of compressor and drills when power project on Little Susitna River goes through. If this project planned by Seattle people is abandoned, he will install his own power plant.

McKEEVER BROS. (Juneau)—On Nelson-Lott claims, Sheep Creek Basin, 2500-ft. tunnel to orebody has been started Arthur Riendeau, who drove Jualin tunnel last summer, has contract for tunnel. Water hammer drills are being used. $250,000 work planned to develop property.

ALASKA GOLD (Juneau)—Thomas Kneebone, who suffered a broken back in Perseverance mine some time ago, brought suit against Alaska Gastineau company for $75,000 damages. Suit thrown out of court by Judge Robert Jennings on June 18. Insufficient evidence as to company's liability.

GRANITE GOLD (Valdez)—Lower adit tunnel is in 600 ft. of 800 ft. planned. Will start raising from adit tunnel to workings in about month. New cross compound compressor, 10-stamp mill, and other new equipment installed. Good showing of ore continues. W. R. Millard, Superintendent.

CALIFORNIA

Amador County

CENTRAL EUREKA (Sutter Creek)—Prospecting by winze below 3100 level. Mill running regularly with 30 stamps dropping.

BUNKER HILL (Amador City)—The 2400 level has been retimbered and development from this point will proceed. In May mill crushed 6700 tons of ore, and produced 200 tons of concentrates, which averaged $80 a ton.

Butte County

SOUTH BANNER (Oroville)—Extensive improvements on Amosky mine are being made. New machinery to cost about $3000 is being installed.

Calaveras County

EAGLE MARBLE QUARRY (Vallecito)—Reported that production will begin at an early date. There is large deposit of marble which it is said can be quarried and shipped at profit.

COLUMBIA (Angels Camp)—Property bonded to E. J. Carter and J. S. Rear. Electric hoist and compressors are being installed. Chile mill will be added to reduction plant Other improvements are contemplated and it is expected to increase milling capacity to 500 tons per day. Property situated between the Utica and Maloneys.

Eldorado County

RISING HOPE (Placerville)—George W. Englehardt is reopening this mine and installing necessary machinery.

UNION EXTENSION (Dixon)—J. Hillhouse and Roy D. Mayes have taken contract to develop mine and furnish machinery.

UNION MINE EXTENSION (Placerville)—Petition filed with State Corporation department asking permission to sell 127,500 shares of capital stock Mine is located at Mud Springs.

FROG POND (Garden Valley)—This property and Collins & Bacchi quartz mines will be reopened and extensively developed by Philadelphia men, owners of Collins & Bacchi, who have recently acquired Frog Pond. J. C. Levitt is superintendent. Properties are developed by shafts to depth of 130 ft. which will be deepened.

Inyo County

CERRO GORDO (Keeler)—Bucket tramway extending from mine to railroad station at Keeler, 29,110 ft., is expected to be ready for service early in July. Tramway will have a capacity of 1500 tons per hour and will effect saving of $2.50 per ton on all ore shipped. Large shipments of high-grade zinc ore are going to smeltery. There is large reserve of silver-lead ore.

Kern County

WERINGER (Woody)—Joseph Weringer, manager, contemplates installation of leaching plant.

ANTIMONY is reported discovered in ledge near Caliente in Old Horse Cañon Samples assayed by Ward M. Mills of High School laboratory showed 96% antimony sulphide and trace of silver.

NEW CREEDE is name of camp recently established in Lone Pine district, 14 miles northeast of Mojave. High-grade gold and silver ore has been disclosed in development work in progress by Williams and Gragoman on No. 5 claim. George Henry of Colorado and Fred and George Ramey and W. H. Bremendorfer of Caliente are engaged in active prospecting and development. Region is being prospected and claims located over area of six miles square.

Los Angeles County

JORDAN OIL (Vernon)—Series of explosions of gasoline wrecked one of four tanks of plant. Spark from a broken electric wire caused explosion and fire which destroyed 250,000 gal. of oil and gasoline. Driver on an autotruck and firemen were severely burned but no lives were lost. The loss is estimated at $100,000.

Madera County

ENTERPRISE (Madera)—More than 200 tons of ore have been extracted and the mill will start within short time. S. R. Johnson is manager.

Nevada County

EXCELSIOR CONSOLIDATED (Truckee)—Preparations being made to reopen mine, which was closed down at time of outbreak of war.

COLUMBIA (Nevada City)—Arrangements being made for reopening mine in July. Has been closed down since accidental death of W. C. Hunter, mining engineer, and two men recently. Mr. Klinkner is manager.

SHADY CREEK PLACERS (Nevada City)—Small dredge is being installed for working old hydraulic tailing. If found successful other installations will be made to work neighboring ravines which contain hydraulic tailing.

NORTH STAR (Grass Valley)—New 100-ft. steel headframe for Central shaft being constructed. Three large steel bins and sorting plant will be constructed within headframe. New 700-hp. electric hoist will have a capacity for handling 4-ton skips from depth of 6000 ft. incline. Expected to complete the installation by August. Reported that Apex contention between North Star and Empire will be taken into the courts. Expert mining engineers have been employed by both companies for several weeks. Settlement out of court is not now expected.

Plumas County

A GOLD NUGGET weighing 2½ lb. was taken from bedrock of a gravel claim on Squirrel Creek by Byron Turney. Nugget is worth about $540. Squirrel Creek gravel mines have produced probably more large nuggets than any other district in county.

San Bernardino County

ORO BELLE (Hart)—By terms of original contract with Tonopah Belmont, 50-ton mill will be built.

Trinity County

TRINITY ASBESTOS (Castella)—Eight miles of new wagon road from mine have been completed. Total length of road from mine to Castella is 25 miles. Seventy-four men are employed on road and 50 more to be added. Sixteen men are employed at mine. First shipment of asbestos will be made upon completion of road which will be about Oct. 1.

UNION HILL (Douglas City)—Two giants are at work on gravel banks of extreme height of 160 ft. Ditch which carries water from Grass Valley to mine has been repaired. Old Headlight mine at Trinity Center, also owned by this company, may remodel its 40-stamp mill and resume mining. Mine enjoyed long period of activity until oxidized ores were exhausted, and now large reserves of base ore justify installation of fine grinding equipment and filters, so that cyanide treatment may be employed. C. W. Shanks is manager.

COLORADO

Boulder County

WHITE RAVEN (Ward)—F. W. Davis pushing contract to sink main shaft 100 ft. and to start new level. Work will throw light on peculiar structure of this orebody which is unique in this district.

UNITED STATES GOLD CORPORATION (Boulder)—Recent litigation has been disposed of in Supreme Court and company now contemplates considerable additional development. Recent work on 400 level of Nyanza vein has opened high-grade ore.

BOULDER TUNGSTEN PRODUCTION CO. (Boulder)—This company is being financed by Chicago capital and anticipates funds allowing it to drive drainage tunnel through claims three miles from Nederland which will both drain and develop. At present there is no active work being done.

WOLF TONGUE MINING (Nederland)—This company is in market for purchase of tungsten in crude form or for tungsten concentrates of from 10% to 50%, for shipment from mines to either Nederland mill or the Primos Chemical Co. plant near Washington, D. C. Development has not been sufficient to provide enough crude ore for Nederland mill which has been running an average of one week in four, hence their wish to purchase outside ore and concentrates.

NEWHOUSE TUNNEL (Idaho Springs)—Engineer's Leasing Co. has opened an 18-in. vein of pay ore at a depth of 2300 ft. below surface. Selected streaks assay up to 8 oz. gold per ton. On 1300 level of Old Town mine leasers have opened streak of high-grade ore assaying 18 oz. gold per ton. Kuykendall & Co., of Denver, leasing on Bellman vein, have opened pocket of ore below tunnel level which assays as high as 7 oz. gold and 60 oz. silver. Argo mill is running full capacity and treating about 100 tons of ore per day.

Gunnison County

YUKON (Parlin)—New air compressor, boiler and hoist being installed at Yukon shaft, old machinery being transferred to Alaska shaft. Ore carries 36% zinc.

Lake County

WESTERN ZINC OXIDE CO. (Leadville)—Smeltery obliged to close down few days during removal of zinc oxide from large flue conducting fumes from furnaces to bag-house. Twelve tons of material was recovered. Crushing facilities have been found inadequate and much of ore is now crushed at Arkansas Valley smeltery before its delivery.

San Juan County

HAMLET (Howardsville)—Mill will start soon treating mine's complex zinc-copper ore carrying gold and silver.

SILVERTON BUSINESS MEN are organizing $50,000 stock company for local subscription, funds so raised to be used in erection and operation of custom cyanide plant.

Teller County

PORTLAND (Victor)—Was given possession, June 29, of Stratton's Independence property in accordance with terms of sale ratified by stockholders May 18.

ROOSEVELT TUNNEL (Cripple Creek)—Breast is even with Elkton mine shaft. New water conrses have been struck and total flow from portal exceeds 12,000 gal. per min. Face will soon be within crater.

MICHIGAN

Iron

MARY CHARLOTTE (Negaunee)—One hundred miners were added to working force here on June 28. There is plenty of ore in stock but large sales have been made recently. Total working force is now 175 hands.

OLIVER (Iron Mountain)—Chapin and Aragon mines were placed on full time June 21. Had been working only four days a week for 16 months. Considerable ore being shipped from both mines.

NEWPORT (Ironwood)—M. A. Hanna Co. has succeeded in disposing of 1,000,000 tons of ore for Newport Mining Co. Will be shipped from Newport at Ironwood and Palms-Anvil at Bessemer. Rapid progress being made at new Newport 14x24 shaft. Last month it was sunk 205 ft.

CLEVELAND-CLIFFS (Ishpeming)—Educational department graduated its first class this week. Graduates who received diplomas are miners and foremen in employ of company who have been taking prescribed work in school for over two years. New ruling of the company states that all shift bosses and foremen will be selected from among graduates. Educational work of company is in charge of Carl S. Stevenson, formerly of Bureau of Mines.

MINNESOTA

Duluth

UNIVERSAL PORTLAND CEMENT CO. (Duluth)—At present rate of construction, it is announced that company's new plant at Duluth will be in operation by Apr. 1, 1916. Plant will have output of 4000 bbl. of cement per day. It is most modern of Universal plants although not the largest. Eight hundred tons of Michigan limestone will be required daily, also 575 tons of slag from the Minnesota Steel Co.'s blast furnaces.

Cuyuna Range

WILCOX (Woodrow)—Now hoisting 500 tons daily. Initial cargo recently received at Point Edward, Ont., showed 13.5% moisture and 59% Fe, being lower in moisture than anticipated.

CUYUNA-SULTANA (Brainerd)—Company is installing some larger equipment at its No. 2 shaft, including 80-hp. locomotive-type boiler, Messinger (Duluth) hoist and Franklin air compressor. After installation shaft will be sunk 25 ft. deeper and cross cutting begun.

Mesabi Range

MEADOW (Aurora)—Shipments from stockpile started this week.

UNION (Virginia)—This mine is heaviest shipper in Virginia district at present time; 65 cars being sent out daily. Only one shift is being worked.

VIRGINIA DISTRICT. About 500 cars of ore being shipped daily from Virginia district, of which 300 come from Alpena operation of Oliver Iron Mining Co.

NORMAN (Virginia)—Oliver company is shipping 26 cars daily from this property. Two shovels are working at Minorca stockpile. Twenty-five cars are being loaded each shift. The Bessemer is sending out a like amount

MAHONING (Hibbing)—This mine is heaviest shipper on Mesabi Range at present; shipping 210 cars daily. Buffalo-Susquehanna, also at Hibbing, comes second with 80 cars. Duluth, Mesabi & Northern road is taking care of about 54,000 tons each day

MONTANA

Beaverhead County

NATIONAL OIL CO. (Dillon)—This company recently organized to drill for oil in Muddy Creek and Sheep Creek basin and in Small Horn Cañon near Dillon where company has located large tracts of oil land. Dr. A. C. Sandberg, of Butte, who heads company, has announced operations will begin at once

BEAVERHEAD-MONTANA COPPER (Argenta)—Ray Coban of Butte has lease and bond on Jackrabbit mine at Argenta and property is to be started up at once by new company which recently organized with capital stock of $100,000. Jackrabbit adjoins property of Butte-Argenta company and recent samples show ore to average 11.9% copper and 22 oz. silver. Company will ship to Salt Lake smelters but is contemplating erection of small concentrator.

Custer County

MONTANA PETROLEUM CO.—Articles of incorporation filed June 20 with clerk of Miles City. Company formed for development of gas and oil territory of Moorehead section in southeastern Montana. Upon finding oil company proposes to build plant and distill product on spot. Drilling operations will be commenced in new field as soon as necessary machinery can be brought there.

Fergus County

BARNES KING (Kendall)—Output of North Moccasin mine for May amounted to $41,044. This was secured from 4728 tons of ore, average yield per ton about $8.70.

Lewis and Clark County

EAST HELENA SMELTERY—Following visit of eastern officers of American Smelting & Refining Co. to East Helena plant, announcement was made by Manager F. M. Smith that another furnace would be blown in at once which will increase output of plant to three-fourths maximum capacity. High price of lead and zinc stimulating mining in these ores, necessitating an expansion at smeltery.

SCRATCH GRAVEL DISTRICT—New discovery has been made in this district on ground bonded by Thomas B. Miller and associates of Helena and located near celebrated Franklin property which is being worked by Cruse estate. It is in line with and about 2000 ft. distant southwesterly from present workings on Franklin lead. Shaft has been sunk on property to depth of 100 ft. and ore is to be stoped for shipment to smeltery as soon as work of running levels has been completed.

Missoula County

IRON MOUNTAIN (Missoula)—To be sold at sheriff's sale to satisfy claim of eastern capitalists. Of late was running behind causing bondholders to foreclose on mortgage.

AMADOR (Amador)—After idleness of several years has been acquired by Sydney L. Shonts and Oscar Nordquist, of Wallace, Idaho, who are preparing to erect 100-ton concentrator. Shaft is 700 ft. deep and is full of water below 400-ft. level.

Park County

MONTANA SCOTCH BONNET CO.—Property of this company, located about 60 miles from Cook City, to be opened up by eastern syndicate. About 4000 ft. of tunnels have been run and bodies of ore assaying $34 to $38 per ton have been opened up. New company intends to begin extensive development immediately.

Silver Bow County

ANACONDA (Butte)—Company has begun unwatering old Lexington mine and will work that property for its zinc ores.

BUTTE & ZENITH CITY (Butte)—Work will be resumed within short time. Mine which was closed down last fall on account of labor conditions, is located about two miles west of Rocker.

BUTTE & GREAT FALLS (Butte)—Development work at property of this company bringing promising results. Returns on samples taken from new orebody opened in crosscut that runs to Genevieve vein gave 11.5% copper, 24.4 oz. of silver and 0.08 oz. of gold. Plans to sink shaft to depth of 500 ft. or more. Hoisting engine will be installed capable to hoist ore from a depth of 1500 ft. and a large pump will be placed on 300 level.

RAINBOW DEVELOPMENT (Butte)—At annual meeting of company held in Duluth voted to issue general mortgage 6% convertible bonds to amount of $400,000 and to increase shares from 80,000 to 150,000. Par value to remain $10. Work is to be resumed at once in shaft where operations were discontinued last fall. Rainbow property adjoins Butte & Superior and has already encountered vein in which Butte & Superior's richest ores occur. Work is to be prosecuted vigorously.

BUTTE & SUPERIOR (Butte)—New flotation machines installed some weeks ago at mill of this company proved satisfactory. Grade of concentrates was raised materially and cost of production lowered. Tons of ore milled in May were 43,380. Tons of concentrates realized were 11,870. Zinc in the concentrates was 12,371,000 lb. Recovery was 88.03%. Concentrates assayed 52.11% zinc. On June 19 company filed regular monthly statement of operations in flotation plant with clerk of court showing 37,633 tons of ore treated in May in flotation plant. Amount of concentrates recovered was 7508 tons. Cost per ton of concentrates recovered, $4.28, and value per ton, $63.82. Total value of concentrates, $479,181. Assay returns of concentrates were: Zinc, 52.055%; lead, 2.767%; copper, 0.558%; silver, 24.149 oz.; gold, 0.0418 oz.

Yellowstone County

ROMAR OIL COMPANY—Will soon commence drilling for oil in Big Wall country, northeast of Roundup and is now negotiating with landowners for leases and oil grants. Same company prospected in Seventy-nine country last year. It is understood company intends to secure leases on 45,000 acres of land.

NEVADA

Clark County

SULTAN—This property, situated near Ripley, was recently purchased by Henry Robbins, who is shipping about 200 tons of zinc carbonate ore monthly.

BULLION (Goodsprings)—Young & Fayle announce that 50-ton dry concentrator will be erected on property at once. Plans for mill are now being made, and it is expected that Sutton, Steele & Steele tables will be used.

FREDERICKSON (Goodsprings)—New dry concentrator now operating at full capacity, and Sutton, Steele & Steele tables are proving successful in handling lead-zinc carbonates. Company is treating custom ore in additon to their own production.

YELLOW PINE (Goodsprings)—Mill producing full contractual allowance of 1500 tons of zinc concentrate per month, together with 200 tons of lead-silver concentrate. Sinking has been resumed in main two-compartment shaft to tap orebody at depth of 900 ft.

ANCHOR (Goodsprings)—Full tonnage of zinc carbonate ore allowed by contract being shipped. Company announces intention of erecting 50-ton dry concentrating mill for treat-

ment of mixed lead-zinc ores. Rolls and dry tables of Stebbins type will probably be used. Roy W. Moore is superintendent.

Esmeralda County

JUMBO EX (Goldfield)—Has increased shipments from 50 tons daily to 150 tons every two days.

FLORENCE (Goldfield)—Is again considering sinking shaft from 1200 to 2000-ft. level.

ORIZABA (Cloverdale)—Property situated six miles west of Cloverdale on Luning Road purchased by L. L. Patrick, of Goldfield, and others. Shaft is down 100 ft., exposing ledge of ore carrying high gold and silver values.

Humboldt County

MERRIFIELD LEASE (Haystack)—Five-stamp mill installed has started up successfully.

Lyon County

YERRINGTON BULLION (Ludwig)—Buildings and equipment will be sold at sheriff's sale to satisfy creditors.

Nye County

CASH BOY (Tonopah)—First shipment of ore made recently to Western Ore Purchasing Co., Millers.

SKAGGS (Round Mountain)—Lease and bond taken on this property by Elko men. Large tonnage medium-grade copper ore developed.

BIG PINE (Manhattan)—New machinery for mill operating on Muskett-Wittenberg lease now arriving and being installed. New 50-hp. hoist has already been set up.

BIG FOUR (Manhattan)—After more than year's idleness, lease granted to Kendall & Bragg, of Goldfield who will start work at once. There is 10-stamp mill on ground.

DEXTER-WHITECAPS (Manhattan)—At special meeting of stockholders held at Tonopah decided to dissolve old corporation and form new one with capitalization of $2,000,000.

Storey County

MEXICAN (Virginia)—On 2300 level work in understope in north drift continued and 30 tons of ore averaging $12.50 per ton extracted. Repairs to mill continued.

COMSTOCK PUMPING ASSOCIATION (Virginia)—Pumps ran successfully all week and water held below 2700 ft. point. East drift being timbered, cleaned out and drains enlarged.

CON. VIRGINIA AND OPHIR (Virginia)—On 1600 level and Ophir 2500 level jointly with Pumping Association have been cleaning out and repairing main north drift from incline station. Distance of 26 ft. made. Total now open, 48 ft with caved ground ahead.

OPHIR (Virginia)—At Central tunnel completed timbering intersection of two north drifts and west crosscut; and preparing to continue old slope in northerly direction. Crosscut near Andes line was timbered and crosscut in Andes ground advanced to 54-ft. point with face in porphyry and quartz. From development and stope above north drift 275 cars of ore saved and 245 tons milled.

JACKET-CROWN POINT-BELCHER (Gold Hill)—Reported that 1083 tons of dump rock sent to mill; two bars of bullion shipped to smeltery. Pumping equipment formerly in Jacket incline installed at 1500 level and placed in operation. Incline being cleaned out and repaired. On Belcher 1300 level southeast drift yielded seven cars low-grade rock. Repairs being made on 1300 and 1400 levels.

UNION CON. (Virginia)—On 2650 level west crosscut advanced to 690 ft. point; face shows porphyry and quartz. Passed through 6-in. stringer that sampled $17.50 per ton. North drift from west crosscut on south boundary line cleaned out and repaired to the 165-ft. point. On 2500 level jointly with Sierra Nevada made good progress opening up west country for prospecting. West crosscut now in good condition to 164-ft. point.

NEW MEXICO

Grant County

BURRO MOUNTAIN (Tyrone)—Extensive grading is being done from company's railroad to new townsite. Contracts have been let for erection of dwelling houses, hospital and stores.

VIRGINIA DISTRICT (Lordsburg)—A 3½-mile spur, from Oil Siding to mines in Virginia Mining District is to be built by Arizona & New Mexico R.R. Contracts have been signed with producing companies and options for rights of way secured. Grading contract is being advertised and bids will be opened at the A. & N. M. offices in Clifton, Ariz. Railroad will be in operation by Sept. 1. Caterpillar tractors now on ore haul will be moved to other mines. Construction of Lordsburg spur will mean opening of now dormant mines and increase of production of mines now operating.

SOUTH DAKOTA

Lawrence County

WASP NO. 2 (Flatiron)—Property is again being operated at close to maximum capacity, which is 500 tons daily, after working day-shift only in mine during winter months.

HILL CITY DEVELOPMENT (Hill City)—Steam hoisting plant and compressor are being set up at main shaft. Shaft down 100 ft. and will be continued to 300 ft. followed by drifting on orebodies.

BISMARCK (Flatiron)—Resumption of milling is planned, property having reverted to original owner, John A. Sandholm, Des Moines Ia., through failure of company to complete purchase. First work to be undertaken will be construction of skipway from mill down hill to C. B. & Q. railway tracks below, over which supplies can be delivered.

ECHO (Maitland)—After suspension of mining since Apr. 29, unwatering of shaft was commenced on June 16. Water will be handled by Cameron No. 5 sinker, operated by compressed air, to furnish air for which 10x12 single-stage compressor, driven by 30-hp. motor, has been erected. Shaft is 135 ft. deep and will be continued with two shifts of miners.

UTAH

Beaver County

BEAVER GOLD (Beaver City)—Arrangements for sinking another 100 ft. have been made.

MAJESTIC (Milford)—Development is being done from 100 and 200 levels at this company's Hoosier Boy property, after shutdown of several months.

LEONORA (Milford)—East-west fissure opened on 400 level shows streak of ore widening as point of intersection with a north-south fissure approaches. This is 30 ft. distant.

MOONDAY (Milford)—Following recent strike at adjoining Cave mine, it is proposed to resume work here. Property opened to depth of 230 ft. and iron ore carrying copper has been found.

Juab County

TINTIC ORE SHIPMENTS for the week ended June 18 were 142 cars estimated at 7100 tons, valued at $177,000, compared to 124 cars week previous; about 900 tons increase.

TINTIC MILLING (Silver City)—Articles of incorporation have been filed, capitalization amounting to 1,000,000 shares, par value 3c. Jesse Knight is president and G. H. Dern, vice-president.

CHIEF CONSOLIDATED (Eureka)—Working forces have been increased, and output for week ended June 18 was 27 cars. Several blocks of ground on 1400 and 1600 levels have been given over to leasers, and more are to follow.

IRON BLOSSOM (Silver City)—Ore has not been found in commercial quantity in cave recently opened by winze from 600 level of No. 3 workings. Prospecting at depth is being continued in this section, productive at higher levels. Twenty-two cars of ore were shipped week ended June 18.

Grand County

GREEN MOUNTAIN MINING & MILLING CO. (Cisco)—Company organized under laws of Utah, 1,500,000 shares, Dr. R. S. Milhee, of Milwaukee, President. Company owns group of claims in La Sal district, 35 miles southeast of Cisco on Denver & Rio Grande R.R. Will install complete equipment of machinery, including 30-hp. gas engine, air compressor, fan, pumps, etc.

Salt Lake County

ALTA CONSOLIDATED (Alta)—A trial shipment of low-grade ore carrying copper, gold, and silver, with excess iron, is to be made as soon as teams can be obtained. Recently three cars of shipping ore were sent to market.

UTAH COPPER (Bingham)—Between 23,000 and 25,000 tons of ore daily are being treated by the Magna and Arthur mills. In May 14,053,000 lb. of copper were produced being 800,000 lb. greater than the previous record month.

CARDIFF (Salt Lake)—Shipments of 50 tons daily are being made. New oreshoot continues to open up satisfactorily; and ore has been followed downward from the main tunnel level for 75 ft. New roadway from mine is practically completed.

SOUTH HECLA (Alta)—The 500 level is producing a good tonnage of first-class ore, and 25 to 30 tons of ore daily are being shipped. As soon as surface water hampering work in the main stope has been got rid of, shipments will probably be increased. Sixteen men are working.

UTAH-APEX (Bingham)—The flotation process for the treatment of slimes will make possible an increase of nearly 10,000,000 lb. a year in output of lead, with cost of less than $20,000 for installation. At present the rate of production is 30,000,000 lb. annually. The bonded indebtedness has been reduced to $40,000; and par and interest are being offered for these but bonds are slow in coming in. Copper ore running 3 to 3½% is being shipped from 300 level, and is stated to be bringing about $10,000 monthly.

Summit County

PARK CITY ORE SHIPMENTS for week ended June 19 were 2479 tons valued at $100,000, compared to 1622 tons week previous.

SILVER KING CONSOLIDATED (Park City)—Shipments for the week ended June 18 were 1,086,640 lb.

SILVER KING COALITION (Park City)—Two shifts are being worked. The May output amounted to 4057 tons of crude ore and concentrates.

WASHINGTON

Stevens County

UNITED COPPER (Chewelah)—First unit of new stamp mill, 60 miles north of Spokane, started up. There are now 44 stamps in operation, treating 125 tons of ore. Station is being cut underground at 1000 level, and hoist equipment will be installed to sink shaft another 1000 ft.

CANADA

BRITISH COLUMBIA

CANADIAN GOLD FIELDS SYNDICATE—This company, which has not been operating since 1901, is being wound up and will make a liquidation of 4.43% to shareholders.

Ontario

ADANAC (Cobalt)—Unwatering of mine has been effected, and crosscutting begun from 200 level of No. 1 shaft. One promising vein has been encountered.

KIRKLAND LAKE (Kirkland Lake)—Rich ore has been encountered at depth of 60 ft. in shaft of McKane claim of this development. Shaft will be put down to 150-ft. level.

GLEN LAKE (Cobalt)—Lease of Foster property held by this company has been extended for another five years. Royalty has been reduced to 15% on all 200 oz. ore and under and 25% on ore of higher grade.

The Market Report

Metal Markets

NEW YORK—June 30

Copper and tin were very dull during the last week, prices remaining substantially unchanged. Lead and spelter were both stronger, particularly the latter, but the aggregate of business transacted in either metal was not large.

Copper, Tin, Lead and Zinc

Copper—The market was dull, the principal producers reporting no sales except for special brands, special shapes, for deliveries at non-competitive points. Being so well sold ahead they are quite unconcerned over the lull in buying and nominally maintain their old price of 20¼c., regular terms. Smaller producers and agencies offer copper at 19¾@20c., regular terms. Some of these sold for delivery in Western markets, which is unusual inasmuch as back freight has to be paid to them and ordinarily they are left to sellers who have refineries further West. However, the aggregate of domestic business during the last week was small, the sales effected being principally for export to England, France and Russia. In view of the declining tendency of Sterling Exchange it is difficult to figure what such sales are going to realize unless they be made on the basis of a net cash price in New York. Considerable sales were thus made upon the basis of 19.60c., which would correspond with about 19.80@19.85, regular terms for the ordinary domestic deliveries.

The Anaconda Copper Mining Co. has introduced a new brand of casting copper, viz., "ABS—Arizona Best Selected." This is refined at the Raritan works from copper produced at Miami, Ariz., which is low in gold and silver, but goes 99¼@99½% in copper.

The unusual disparity between the prices for electrolytic and casting copper—about 1c. per lb.—still prevails.

There are reports of improvement in domestic copper consumption, particularly on the part of the sheet rollers.

Copper Sheets are understood to have brought 25@26c. per lb. The principal manufacturer has withdrawn all quotations. Wire is quoted at 21½@22c. per lb. at mill.

Copper Exports for the week ended June 12 are given by the Department of Commerce at 11,064,237 lb. The larger items were 7,121,938 lb. to Great Britain and 2,921,375 lb. to France. Imports for the week were 2,518,379 lb. metal and 733,962 lb. in ore and matte; 3,252,341 lb. in all. The imports were from Peru, Canada, Cuba and Japan.

Tin—This market was quiet, only a small volume of business being reported. The deliveries in June were about 3900 tons—a large figure coming on top of the huge total of 5600 tons in May.

Tin production in Bolivia in 1914, according to official figures was 36,262 metric tons of concentrates averaging 60% tin. This is a decrease of 8332 tons from the previous year.

Tin production of the Federated Malay States, five months ended May 31, was 20,599 long tons in 1914 and 17,816 tons in 1915; a decrease of 2783 tons this year.

Lead—The outside speculative holdings appear to have been nearly all liquidated, as result of which the market gradually returned to the producers' prices, and some of the producers even made sales at their figures. At the close this market was distinctly firmer.

The exports of this metal continue heavy, as is shown in the table given on the following page.

Spelter—A moderate volume of business was done at advancing prices, particularly in the early half of the week. The bulk of this was in contracts for delivery late in the year at 18@19c. Spelter for early delivery sold up to 21c., but the market for this was spotty. This rally in the spelter market has not been characterized by any such crazy buying as there was early in June. When the price for prompt spelter rose to 21c. lots from second hands began to be offered at a little above that figure.

Exports from Baltimore for the week included 336,156 lb. spelter and 164,260 lb. zinc dross to Liverpool.

Zinc Sheets are lower; base price $27 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras charged.

Other Metals

NEW YORK—June 30

Aluminum is still quite active, but seems to be in rather better supply than it has been. More domestic metal is available. Quotations are a shade easier, at 30@32c. per lb. for No. 1 ingots, New York.

Antimony remains strong, though not especially active. Business is confined to necessary supplies. Ordinary brands, chiefly Chinese and Japanese, are held at 37½@40c. per lb. Cookson's is in short supply and 47@50c. per lb. is named.

Nickel is steady and unchanged. Ordinary forms are 40@45c. per lb., according to size and terms of order. Electrolytic, 3c. per lb. higher.

DAILY PRICES OF METALS IN NEW YORK

			Copper	Tin	Lead		Zinc

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York, 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

		Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
June	Silver	Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts. per Lb.
24	23 3/16	80⅞	82	94½	20.33	168¾	166½	23¾	4.95	87½	18.63
25	23 1/16	82¼	83½	94½	20.33	171	168	24⅜	5.21	91	19.38
26	23 1/16	...	...	....	....				....	....	....
28	23	82¼	83½	94½	20.33	171	168	24⅜	5.29	92½	19.50
29	22⅞	82⅜	83⅞	95	20.43	171⅜	168½	25 3/16	5.44	100	21.29
30	22⅞	81¼	83¼	95	20.43	172	168¾	26¼	5.59	100	21.29

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Recent London quotations for ordinary forms of refined nickel are £216 per long ton, which is equal to 46.9c. per lb.

Quicksilver is in good demand and prices continue strong. New York quotation for wholesale lots is $90@95 per flask for large lots. Smaller orders bring $95@100 per flask. San Francisco reports by telegraph a somewhat variable market, prices ranging from $85 up to $95 per flask ,with demand in excess of stocks. London has had a sharp advance, the present price being £16 per flask, with £15 17s. 6d. quoted from second hands.

Minor Metals—Current sales of bismuth are at $2.75@3 per lb. New York. The London price is quoted at 10s., or $2.40 per lb. there—**Cadmium** is quoted at 6s., or $1.44 per lb. in London; $1.50 per lb., New York.—**Tellurium** is reported sold at 80s., or $19.20, per lb. in London.—**Selenium** is quoted at $2@3 per lb. New York for larger quantities; $4.50@5 for retail lots.

LEAD AND ZINC EXPORTS

Imports and exports of lead in April and the four months ended Apr. 30 are reported by the Department of Commerce as below, in short tons:

	April		Four Months	
	1914	1915	1914	1915
Imports	2,389	3,193	7,536	22,322
Exports	3,663	25,019	5,438	49,573

The exports included reëxports of foreign lead. The imports are nearly all in ore and base bullion, sent here to be refined.

Imports and exports of zinc or spelter for April and the four months ended Apr. 30 were as follows, in short tons:

	April		Four Months	
	1914	1915	1914	1915
Exports	60	8,842	481	50,523
Imports	208	23	459	264

Imports of zinc ore in April this year were 12,988 tons, estimated as containing 12,461,830 lb. zinc.; for the four months, 27,897 tons, with 23,081,296 lb. zinc contents. Imports of zinc dust for the four months were 1,792,414 lb. this year.

METAL EXPORTS AND IMPORTS

Spanish Metal and Mineral Exports three months ended Mar. 31, as reported by "Revista Minera," in metric tons:

	Metals		Ores etc.	
	1914	1915	1914	1915
Iron	1,871	37,515	1,979,396	962,157
Copper	4,481	3,934	35,380	11,198
Copper precipitate	2,579	2,044	..	..
Lead	41,999	32,936	708	183
Zinc	683	187	25,444	874
Quicksilver	619	372	..	..
Manganese	..	..	5,425	1,970
Pyrites	..	..	776,422	333,372
Salt	..	..	143,868	189,367

Imports of coal for the three months were 366,305 tons, a decrease of 328,988 tons from 1914; of coke, 37,251 tons, a decrease of 54,274 tons.

Gold, Silver and Platinum

NEW YORK—June 30

Gold continues to come from Ottawa on London account. More will doubtless come, as exports to Europe increase.

Gold output of the Kolar field in Mysore, India, five months ended May 31, was $5,051,562 in 1914, and $5,250,118 in 1915; an increase of $198,556 this year.

Sterling Exchange in New York reached the lowest point on record, having sold one day at a point below 4.76, which is 2% below par.

Platinum is still quiet, with business on a moderate scale. Prices show no material change. Dealers ask $37@39 per oz. for refined platinum and $41@44 per oz. for hard metal.

Our Russian correspondent writes that the improvement in the market continues. At Petrograd there is a demand for considerable quantities for shipment abroad, especially to Sweden. At Ekaterinburg there have been good transactions in small quantities. Quotations at Ekaterinburg are 8@8.50 rubles per zolotnik—average, $31.02 per oz.; at Petrograd, 33,500@33,800 rubles per pood—average, $32.78 per oz.—for crude metal, 83% platinum.

Silver—The market has continued dull and stagnant, and owing to lack of buying orders has been forced down to 22⅞d in London. The selling pressure has been light or prices would be lower still. India is only a small buyer and China is not in the market. Price closes steadier at 48c. in New York.

Silver shipments from London to the East from Jan. 1 to June 16 are reported as below by Pixley & Abell:

	1914	1915	Changes
India	£3,617,000	£2,562,000	D. £1,055,000
China	40,000	5,000	D. 35,000
Total	£3,657,000	£2,567,000	D. £1,090,000

Imports of silver in Great Britain five months ended May 31, were valued at £4,345,647; exports, £3,697,176; excess of imports, £648,471, which compares with an excess of exports of £1,272,671 last year.

Zinc and Lead Ore Markets

JOPLIN, MO.—June 26

Blende, high price $112.50 per ton of 60% zinc; premium ore, $110@100; medium grades, $100@90; lower grades down to $70; calmine, base 40% zinc, $75@50; average price, all grades of zinc, $96.36 per ton. Lead, high price, $75; base, $72@60 per ton 80% metal content; average price, all grades of lead, $64.35 per ton.

Producers are between opposing forces now. Prices are receding and a large number of miners went out on strike again tonight for a further raise in wages. Premium ore dropped $18 this week and $7 the previous week, and the decline is hurting. The strike among miners, it is believed, will be settled by the men returning to work Monday without advance, but if this is not done the output of the largest producing mines of Webb City will be severely curtailed.

SHIPMENTS, WEEK ENDED JUNE 26

	Blende	Calamine	Lead	Values
Totals this week	11,369,550	760,920	2,270,430	$656,490
Totals this year	299,601,790	25,187,400	43,029,300	11,774,710

Blende value, the week, $559,970; 6 months, $10,136,320.
Calamine value, the week, $23,480; 6 months, $522,660.
Lead value, the week, $73,040; 6 months, $1,115,400.

PLATTEVILLE, WIS.—June 26

The base price paid this week for 60% zinc ore was $95@110 per ton. The base price paid for 80% lead ore was $68 per ton.

SHIPMENTS, WEEK ENDED JUNE 26

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	3,449,750	80,000	747,860
Year	92,126,380	3,202,090	13,204,730

Shipped during week to separating plants, 4,516,400 lb. zinc ore.

Iron Trade Review

NEW YORK—June 30

The iron and steel markets are still gaining with large increases in orders in many lines, and with domestic as well as foreign business contributing to the improvement. Just what proportion the export business bears to the total it is not easy to say definitely, as orders for material are frequently so divided up that their ultimate destination cannot be determined. Undoubtedly it is large and includes a quantity of rail and of steel for railroad equipment as well as for the war munitions.

Naturally prices are firming up and advances are recorded in a number of lines. The upward movement is not rapid but is generally held.

The pig-iron market is not keeping pace with steel, but is generally lagging behind. Pig iron production is increasing, but the gain is all with the steel works furnaces, and the merchant stacks are making little progress, hardly holding their own.

The ferromanganese situation is not improving, and it looks as if the shortage might be a serious one before long. Some manganese ore is coming in, but receipts are much below last year. The English receipts also show a heavy decrease.

Exports from Baltimore for the week included 17,799,804 lb. billets and skelp steel, 3,420,700 lb. bars and wire rods, all to Great Britain.

Imports at Baltimore for the week included 8260 tons manganese ore from Brazil and 2017 tons ferromanganese from Liverpool.

Foreign Trade of the United States in iron and steel and in manufactures thereof four months ended Apr. 30 is valued by the Department of Commerce as follows:

	1914	1915	Changes
Exports	$74,414,334	$80,812,326	I. $6,397,992
Imports	10,306,027	5,948,722	D. 4,357,305
Excess, exports	$64,108,307	$74,863,604	I. $10,755,297

The incerase in exports this year, as compared witb 1914, was 8.6%; while there was a decrease of 42.3% in the imports

PITTSBURGH—June 29

The steel mills are now operating at slightly more than 80% of rated capacity, and operations are still increasing, pointing to a 90% operation or better by the beginning of August There will be no dull summer in the steel trade this year. Yesterday the Carnegie Steel Co. started the North Sharon works, for the first time in about two years, and now has only one idle steel plant, the small Columbus bessemer works. This plant will not be started in the near future, as recently reported, but if additional billets and sheet bars are required the Riverside plant at Wheeling or the National Tube Co. will be started for this purpose. The Carnegie Steel Co. is negotiating for billets and sheet bars to apply against some of its obligations in the East, particularly for the Pencoyd works of the American Bridge Co. It only buys steel when under unusual pressure.

Exports of steel that are reported by weight are expected to total between 250,000 and 300,000 gross tons for June, against 223,000 tons in April, for which month the government statistics have just been published. Exports of manufactures involving steel, not reported by weight, are unusually heavy, exports of passenger automobiles and trucks, machine tools, locomotives and freight cars being unusually heavy, while shrapnel, loaded and unloaded, not reported in the statistics by weight, involve a large quantity of steel. Altogether the exports of steel and manufactures involving steel now represent fully 20% of the current steel output, and may possibly amount to nearly 25%, the export rate exceeding the average rate in 1912, the banner export year.

Steel prices show only a slight advancing tendency, the strength of the market being shown chiefly by the heavy bookings for early deliveries and the indisposition of the mills to book for late deliveries. As a whole the actual shipping orders entered run from 15 to 30% above the current shipments. The Pittsburgh and western mills have nearly all withdrawn the 1.20c. price on bars, plates and shapes for prompt shipment, and are quoting 1.25c. for prompt or third quarter. Some mills east of Pittsburgh are still on the 1.20c. basis. Railroad spikes are up $1 a ton to 1.40c., and cold rolled strip steel is up $8, to 2.85c., base. Shafting is firming up, with 68% off list difficult to do and some producers quoting 66% off list.

The iron mill wage scale of the Amalgamated Association was arranged on Saturday at Atlantic City, on the basis of continuing the present scale for the twelvemonth. The men had asked advances, but the iron mills have not participated in the steel trade improvement sufficiently to be willing to grant any advances.

Pig Iron—The local pig iron market continues quiet, not showing any improvement, when the steel trade proper has improved so much. Recent sales to Westinghouse interests, instead of being at exceptionally low prices, now prove to be at prices that can be done again, and the market on Valley foundry iron is quotable 25c. lower than formerly, making the lowest level since 1904. Girard furnace in the Mahoning Valley will blow out this week, after being in blast only three or four months, finding prices obtainable unremunerative. We quote: Bessemer, $13.75; basic, $12.65@12.75; foundry and malleable, $12.50@12.75; forge, $12.25@12.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—Small spot lots are commanding $105@115, regular contracts remaining at $100, Baltimore.

Steel—The Pittsburgh mills are practically out of the market and the Youngstown mills, with a little unsold capacity, are conserving this supply and quoting advanced prices, at about $29 for billets and $31 for sheet bars, prices delivered Pittsburgh being $1.05 higher. Rods are stronger, at $25.50@26, Pittsburgh.

FOREIGN IRON

Steel production in Germany in April was 1,012,344 metric tons, being 85,929 tons less than in March. For the four months ended Apr. 30 the total this year was 4,020,298 tons.

IRON ORE

Statistics compiled by the Lake Superior Iron Ore Association show that the shipments of ore from docks to furnaces during May amounted to 2,797,481 tons. The tonnage on dock June 1 was 5,970,115, compared with 5,772,462 tons on dock June 1 last year.

Imports at Baltimore for the week included 1600 tons manganese ore from Spain and 1731 tons from Liverpool, 3331 tons in all.

Exports of manganese ore from India in the fiscal year ended Mar. 31 were 718,040 tons in 1913-14 and 440,590 tons in 1914-15; a decrease of 277,450 tons.

Imports of manganese ore in Great Britain five months ended May 31 were 205,217 tons in 1914, and 107,297 tons in 1915; decrease, 97,920 tons.

Imports of Iron Ore into the United States in April were 91,561 tons, which is 3159 tons more than in March, but 20,251 tons less than in April, 1914. The chief items were 73,811 tons from Cuba, 18,725 from Sweden, 7800 from Newfoundland and 6256 from Spain. For the four months ended Apr. 30 the imports were 394,739 tons in 1914, and 334,022 in 1915; a decrease of 60,727 tons this year.

Imports of Iron Ore in Great Britain five months ended May 31 were 2,070,224 long tons in 1914, and 1,939,719 in 1915; decrease 130,505 tons.

OTHER ORES

Recent quotations for rare ores in Great Britain are: Molybdenite, 90% MoS_2, $28.80 per unit. Tungsten ore, wolfram, over 65% WO_3, $9.60 per unit; scheelite, 70%, $9.36@9.60 per unit.

Tungsten, Ore.—The schedule of prices now paid for tungsten ore delivered at the Primos Mill, is as follows: $2 a unit for 1% ore, with an increase of 50c. a unit for each additional unit up to 5%, which is worth $4 a unit; an increase of 10c. a unit up to 40% ore, which is worth $7.50 a unit; then an increase of 5c. a unit up to 50% ore, which is worth $8 a unit; then an increase of 10c. a unit up to 60% ore, which is worth $9 a unit. The sampling charge on lots assaying less than 2% is $2 a ton. On small lots worth less than $50 a charge of $5 is made for sampling and assaying. The Primos mill is at Lakeville, Colo., in the district where most of the ore is mined.

FERRO-ALLOYS

Recent quotations for ferro-alloys in Great Britain are as follows: Ferrochrome, from $121.67 per ton for 10% carbon up to $155.75 for 4% carbon. Ferrosilicon, 25%, $51 per ton; 45%, $70.50 per ton. Ferromolybdenum, 70-80%, $4.32 per lb. Ferrotungsten, $1.34 per lb. for 75-85% tungsten and under 1% carbon; tungsten metal, powder, $1.46 per lb. for 96-98% pure.

COKE

Connellsville—The wage cuts made in the fore part of 1914 by the majority of independent coke producers are being eliminated by a return to the Frick scale, announcements to this effect having already been made by the Connellsville Central Coke Co., the Struthers Coal & Coke Co., the Republic Iron & Steel Co., the Bessemer Coke Co. and the Washington Coal & Coke Co. The last named had a strike last week which was settled by restoring the old rates and others have been posting announcements to hold their men, as a labor shortage is regarded as certain in the near future. The merchant coke market, however, remains dull. The wage advance will doubtless stiffen operators' views and may correspondingly delay further buying. We quote: prompt furnace, $1.50@1.55; contract to Jan. 1, $1.75; prompt foundry, $2@2.50; contract, $2.20@2.50, per net ton at ovens.

Chemicals

NEW YORK—June 30

The general market is gradually steadying and shows a better tone on moderate business in most lines.

Arsenic—Demand is only fair, but prices show no change. Quotations are about $4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is steady, with no material change in prices. Quotations are $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller orders.

Nitrate of Soda—The market continues strong and steady, although transactions are rather variable in quantity. Quotations are 2.20c. per lb. for spot and all positions this year.

Potash Salts—The Department of Commerce reports that the imports of potash salts into the United States for the five months ended May 31 were, in pounds:

	1914	1915
Carbonate of potash	9,867,075	8,396,034
Hydrate of potash	3,462,638	2,016,942
Nitrate of potash	1,079,045	6,855
Cyanide of potash	275,977	828,527
Other potash sales	2,704,391	2,064,260

The imports of potash salts used as fertilizers were as follows for the five months, in long tons:

	1914	1915
Kainit	239,362	3,786
Manure salts	81,669	12,456
Sulphate of potash	21,313	8,806
Muriate of potash	105,759	56,135

The large decreases this year are, of course, due to the stoppage of imports from Germany.

The Mining Index

This index is a convenient reference to the current literature of mining and metallurgy published in all of the important periodicals of the world. We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be made with order. Coupons are furnished at the following prices: 20c. each, six for $1, 33 for $5, and 100 for $15. When remittances are made in even dollars, we will return the excess over an order in coupons, if so requested.

COPPER

1311—ALLOYS—Titanium-Aluminum Bronze. W. M. Corse and Charles Vickers. (Metal Ind., May, 1915; 1¾ pp.) 20c.

1312—AURIFEROUS BOTTOMS—Note on the Concentration of Gold in Bottoms in the Converter. H. F. Collins. (Bull. 128, I. M. M., May 13, 1915; 8 pp.) 40c.

1313—CHILE COPPER CO. Ready for Operations. (Min. and Eng. Wld., May 29, 1915; 1¾ pp., illus.) 20c.

1314—CHUQUICAMATA—The Leaching-Plant at Chuquicamata. Lincoln C. Rogers. (Min. Mag., May, 1915; 6 pp., illus.) 40c.

1315—COPPER REFINING—Ueber die elektrolytische Kupferraffination. Franz Altneder. (Metall u. Erz., May 8, 1915; 5½ pp., illus.) An elementary article on copper refining.

1316—LEACHING—A Case for Copper Hydrometallurgy. Inexpensive and Efficient Treatment of Smelter Flue Dust and Carbonate Ore. Geo. C. Westby. (Met. and Chem. Eng., May, 1915; 2 pp., illus.) 40c.

1317—OKLAHOMA—Copper Deposits in the "Red Beds" of Southwestern Oklahoma. A. E. Fath. (Econ. Geol., Feb.-Mar., 1915; 11 pp., illus.)

1318—SOUTH AFSTRALIA—Pernatty Copper Deposits, South Australia. J. Andrew Wauchope. (Min. and Eng. Rev., Apr. 5, 1915; 3 pp.) 40c.

1319—SMELTING Methods at Magistral, Durango, Mex. Robert W. Bissell. (School of Mines Quart., Nov., 1914; 8 pp.) 40c.

GOLD DREDGING AND PLACER MINING

1320—ALASKA—Koyukuk Placer-Mining District. (Eng. and Min. Journ., June 12, 1915; 1¼ pp.) 20c.

1321—DEVELOPMENT METHODS at Fairbanks. Hubert I. Ellis. (Eng. and Min. Journ., June 12, 1915; 6¾ pp., illus.) 20c.

1322—METALLURGY—The Metallurgy of Alluvial Mining. John M. Nicol. (Min. and Sci. Press, May 29, 1915; 4 pp., illus.) 20c.

1323—VALUATION of Dredging Ground. J. J. Bristol. (Min. and Sci. Press, May 29, 1915, ½ p., illus.) 20c.

GOLD AND SILVER CYANIDING

1324—CHURCHILL MILLING CO.—Cyaniding Practice of Churchill Milling Co., Wonder, Nev. E. E. Carpenter. (Bull. A. I. M. E., June, 1915; 15 pp., illus.)

1325—MINERALIZED WATERS—Discussion on "The Effect of Mineralized Waters in Cyanide Plants." Thomas B. Stevens and W. S. Bradley. (Bull. 128, I. M. M., May 13, 1915; 1¾ pp.) 40c.

1326—PRECIPITATION—Discussion on "The Precipitating Action of Carbon in Contact with Auriferous Cyanide Solutions." W. R. Feldtmann. (Bull. 128, I. M. M., May 13, 1915; 16½ pp.) 40c.

1327—RAND—Metallurgical Practice in the Witwatersrand District, South Africa. F. L. Bosqui. (Advance copy, A. I. M. E., Sept., 1915; 37 pp., illus.)

1328—SOLUTIONS—Assay of Cyanide Solutions. C. E. Roodhouse. (Min. and Sci. Press, May 15, 1915; ¾ p.) 20c.

1329—SOLUTION—The Morro Velho Method of Assay of Gold-Bearing Cyanide Solutions. Donald M. Levy and Harold Jones. (Bull. 128, I. M. M., May 13, 1915; 2¼ pp.) 40c.

1330—TESTING OF ORES for the Cyanide Process. Welton J. Crook. (Pahasapa Quart., May 1915). Continuation of article previously indexed.

1331—TESTING SOLUTIONS—Notes on the Practical Testing of Working Cyanide Solutions. Edward H. Groghan. (Journ. Chem., Met. and Min. Soc. of So. Afr., Apr., 1915; 5 pp., illus.) 60c.

1332—TUBE MILL—The Use of Scoop Discharges in Tube-Mills. Walford R. Dowling. (Journ. Chem., Met. and Min. Soc. of So. Afr., Mar., 1915; 6 pp., illus.) 60c.

GOLD AND SILVER—GENERAL

1333—AMALGAM EFFICIENCY—The Relative Efficiency of Various Amalgams in the Recovery of Gold. Francis A. Thomson and Robert Keffer. (Met. and Chem. Eng., June, 1915; 3½ pp.) 40c.

1334—COBALT LAKE DRAINAGE PROJECT. O. L. Flanagan. (Can. Engr., May 20, 1915; 5½ pp., illus.) 20c.

1335—GOLDFIELD Re-visited—I and II. T. A. Rickard. (Min. and Sci. Press, May 22 and 29, 1915; 6 pp., illus.) 40c.

1336—RUSSIA—The Eiderlinsky Gold Mines. Nicholas T. Truschkoff. (Eng. and Min. Journ., June 12, 1915; 4 pp., illus.) 20c.

IRON AND STEEL METALLURGY

1337—ALLOYS—Iron, Carbon and Phosphorus. J. E. Stead. (Advance copy, Iron and Steel Inst., 1915; 41 pp. and 17 plates, illus.)

1338—ALLOYS—Researches on the Iron, Silicon and Carbon Alloys. Geo. Charpy and Andre Cornu-Thenard. (Advance copy, Iron and Steel Inst., 1915; 31 pp., illus.)

1339—BLAST-FURNACE Plant Auxiliaries and General Arrangement. J. E. Johnson, Jr. (Met. and Chem. Eng., June, 1915; 5⅓ pp., illus.) 40c.

1340—BURNING—The Detection of Burning in Steel. J. E. Stead. (Advance copy, Iron and Steel Inst., 1915; 5 pp. and 5 plates, illus.)

1341—CORROSION of Iron in Aqueous Solutions of Inorganic Salts. J. Newton Friend and Peter C. Barnet. (Advance copy, Iron and Steel Inst., 1915; 17 pp., illus.)

1342—CORROSION—Protection of Metal Structures. Frederic H. Fay. (Proc. Engrs., Soc. of W. Penn., Mar., 1915; 108 pp., illus.) A 29-page bibliography of metal corrosion and protection is included in this paper. 60c.

1343—CORROSION—The Removal of Rust by Means of Chemical Reagents. J. Newton Friend and C. W. Marshall. (Advance Copy, Iron and Steel Inst., 1915; 7 pp., illus.)

1344—ELECTRIC FURNACE for Reheating, Heat Treating and Annealing. T. F. Baily. (Iro. Eng. Soc. W. Penn., Apr., 1915; 29 pp.) 40c.

1345—ELECTROLYTIC IRON—The Effect of Boron upon the Magnetic and Other Properties of Electrolytic Iron Melted in Vacuo. Trygve D. Yensen. (Bull. 77, Univ. of Ill., Mar. 22, 1915; 19 pp., illus.) 20c.

1346—FLUE-DUST SINTERING PLANT at Gary. (Iron Age, May 27, 1915; 2½ pp., illus.) 20c.

1347—FOUNDRY—Safety in Foundry Operations. Magnus W. Alexander. (Metal Ind., May, 1915; 2 pp.) Paper before joint meeting of Am. Fdymen's Assn. and Am. Inst. of Metals. 20c.

1348—GERMAN "IRIDIUM" Steel. (Can. Engr., May 27, 1915; ¼ p.) 20c.

1349—KILNS—Rotary Sintering Kilns at Gary. H. Cole Estep. (Iron Tr. Rev., May 20, 1915; 3 pp., illus.) 20c.

1350—LOS ANGELES as an Iron and Steel Center. C. Colcock Jones. (Min. and Oil Bull., May, 1915; 6 pp.)

1351—OPENHEARTH FURNACE—The First Openhearth Furnace in Southern California. (Min. and Oil Bull., May, 1915; 1¼ pp., illus.)

1352—PURE IRON—The Manufacture and Use of Pure Iron. Howard See. (Journ. Assn. Eng. Soc., Apr., 1915; 9 pp., illus.) 40c.

1353—SPECIAL STEELS—Brinell Hardness and Tenacity Factors of a Series of Heat-Treated Special Steels. Andrew McWilliam and Ernest Jefferson Barnes. (Advance copy, Iron and Steel Inst., 1915; 10 pp.)

1354—SPECIAL STEELS—The Thermo-Electric Properties of Special Steels. Eugene L. Dupuy and Albert M. Portevin. (Advance copy, Iron and Steel Inst., 1915; 30 pp., illus.)

1355—SULPHIDES IN STEEL INGOTS—Supplementary Notes on the Forms in which Sulphides May Exist in Steel Ingots. J. O. Arnold and G. R. Bolsover. (Advance copy, Iron and Steel Inst., 1915; 6 pp., illus.)

1356—STRESS-STRAIN LOOPS for Steel in the Cyclic State. Prof. J. H. Smith and G. A. Wedgewood. (Advance copy, Iron and Steel Inst., 1915; 33 pp. and 8 plates, illus.)

1357—WAR—The War's Effect on Iron Industry. John Birkinbine. (Iron Tr. Rev., May 27, 1915; 3½ pp., illus.) 20c.

LEAD AND ZINC

1358—ARSENATE OF LEAD—The Valuation of Commercial Arsenate of Lead. R. H. Robinson and H. V. Tartar. (Journ. Ind. and Eng. Chem., June, 1915; 3 pp.)

1359—CAMPBELL PROCESS—Electromagnetic Zinc-Ore Treatment by the Campbell Process. L. E. Ives. (Eng. and Min. Journ., June 5, 1915; 1¼ pp., illus.) 20c.

1360—LEAD POISONING in the Manufacture of Storage Batteries. Alice Hamilton. (Bull U. S. Bureau of Labor Statistics, Dec. 15, 1914; 38 pp., illus.)

1361—NEW MEXICO—The Hanover Mining District of New Mexico. Faris V. Bush. (Min. and Eng. Wld., May 1, 1915; 3 pp., illus.) 20c.

1362—SPELTER—Analysis of Spelter. (Journ. Ind. and Eng. Chem., June, 1915; 1½ pp.)

1363—WISCONSIN—Mining and Milling of Lead and Zinc Ores in the Wisconsin District, Wisconsin. Clarence A. Wright. (U. S. Bureau of Mines, 1915; 39 pp., illus.) 20c.

OTHER METALS

1364—CARNOTITE—On Carnotite Deposits—and the Rand Banket. Chester T. Kennan. (Min. and Sci. Press, Apr. 17, 1915; 1¾ pp.) 20c.

1365—MONAZITE—Brazilian Monazite Sands Lie in Coastal Strip. Alfred L. M. Gottschalk. (Min. and Eng. Wld., May 15, 1915; 1½ pp.) 20c.

1366—PLATINUM—Occurrence of Platinum at Boss Mine, Nevada. J. C. Kennedy. (Min. and Eng. Wld., May 22, 1915; 2 pp.) 20c.

1367—RADIUM—Practical Methods for the Determination of Radium. I—Interchangeable Electroscope and Its Use. S. C. Lind. (Journ. Ind. and Eng. Chem., May, 1915; 4 pp., illus.) 60c.

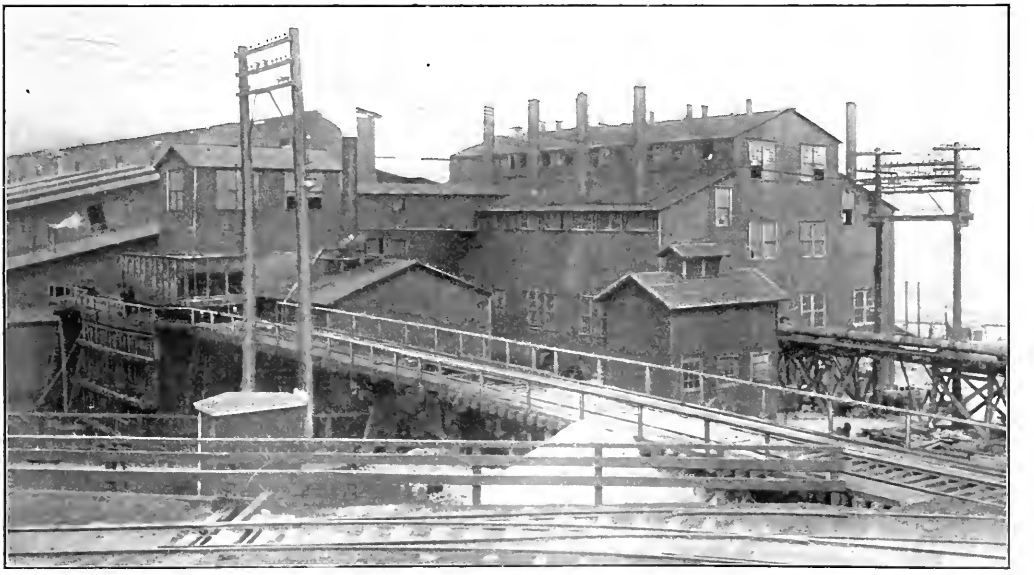
Anaconda Coal-Pulverizing Plant

By E. P. Mathewson*

SYNOPSIS—A description of the new plant now being built at Anaconda, Mont., to supply coal-dust fuel for the reverberatory furnaces at the Washoe Reduction Works.

The Anaconda Copper Mining Co. is installing at its Washoe Reduction Works, Anaconda, Mont., one of the largest and most modern plants for pulverizing coal to be used as fuel in firing reverberatory furnaces: half the plant is now in operation and the rest will be ready in a short time. The building is completed and all the machinery is on the ground.

The main building is of steel and adjoins the reverberatory building on the east. The accompanying picture is a general view of the structure. At the left is shown the temporary coal bin; and next the temporary shed in which is operated one of the Ruggles-Coles driers. The pulverizing machinery is in the large building at the right. The layout of the pulverizing plant is shown in the general plan presented on the succeeding page.



Coal-Pulverizing Plant at Washoe Reduction Works, Anaconda

The coal is received in cars of 50 tons' capacity; these dump into a bin from which the coal passes to two 30x30-in. Jeffrey single-roll coal crushers having a capacity of from 80 to 130 tons per hour. The maximum size of the coal leaving these crushers is 2 in. From the crushers the coal discharges into two manganese-steel-chain bucket elevators which deliver the coal upon a 30-in. conveyor belt equipped with an automatic tripper so arranged that it will distribute the coal evenly in a steel bin having a capacity of 1000 tons. From this storage the coal is drawn upon a 24-in. belt conveyor through automatic-feed chutes which feed the coal upon the belt only when it is in motion. This conveyor belt passes over a Dings magnetic pulley, which removes all scrap iron, nails, spikes, etc., from the coal, and discharges the coal into the boot of an elevator which feeds into three Ruggles-Coles indirect-heat driers. These driers in the completed plant will be fired with pulverized coal.

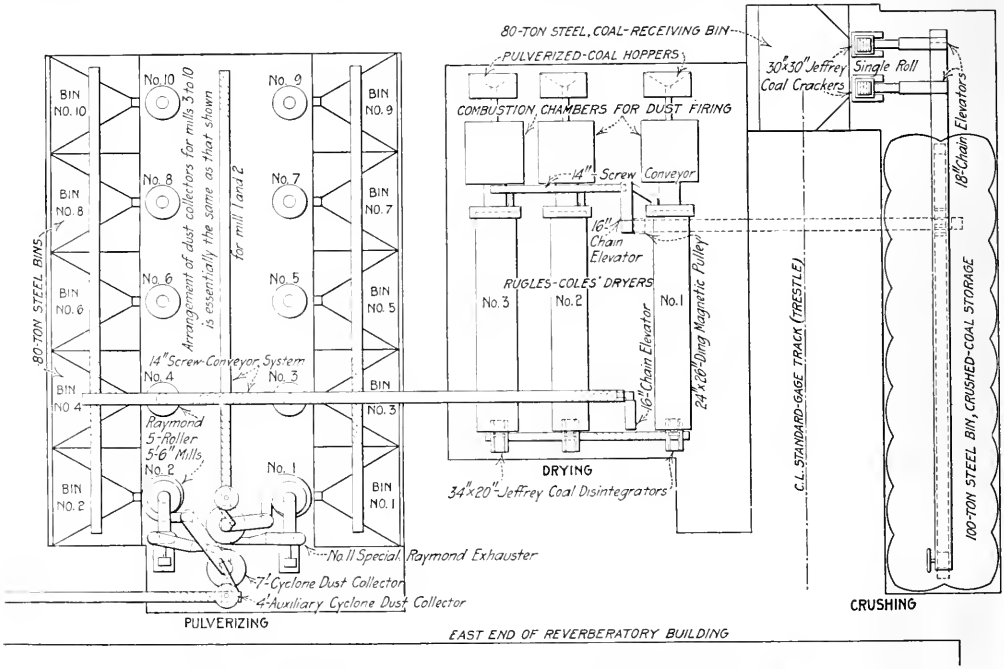
From the drier the coal is discharged on three Jeffreys 20x34-in. coal disintegrators which reduce the coal to $\frac{1}{4}$-in. size. From the disintegrators the coal is conveyed by a 14-in. screw conveyor to the boot of a manganese-steel-chain bucket elevator which discharges into a series of 14-

*Manager, Washoe Reduction Works, Anaconda Copper Mining Co., Anaconda, Mont.

in. screw conveyors delivering the coal into 10 steel hoppers, each one of which is placed above and in front of a Raymond Bros. five-roller pulverizer. These pulverizers are electrically driven and so pulverize the coal that 96% of it will pass through a 100-mesh screen. The pulverizers are operated on the vacuum system, a blower being placed above each mill which draws the coal from the mill as fast as it is reduced to the required fineness and discharges it into a Cyclone collector, where the coal is separated from the air. The air returns in a closed circuit to the Raymond mill. From the collectors the pulverized coal is delivered by a system of 14-in. screw conveyors, in airtight housings, to a 50-ton storage hopper at the firing end of each reverberatory furnace. From this hopper the coal is fed into the furnaces by five Warford coal burners.

as it drops from the conveyor housing is drawn through the four pipes into the mixing chamber, and all of the coal dust entering the mixing chamber is drawn to the end of the blast-air nozzle and thence into the furnace through 5-in. pipes, which in turn discharge into 8-in. pipes. The space between the 5- and the 8-in. pipes allows for secondary air to be drawn in as required to obtain complete combustion of the coal.

The burner and feeder are so arranged that the coal, the primary and the secondary air are under absolute con-

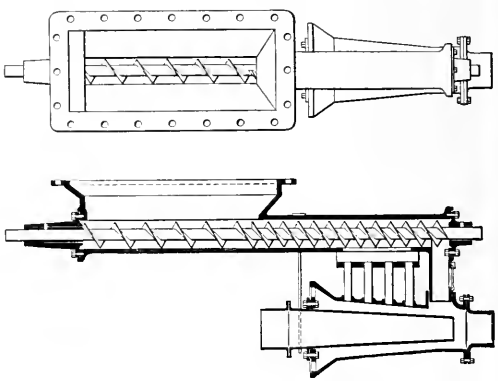


General Arrangement of Coal-Pulverizing Plant at Anaconda, Mont.

The Warford Coal Burner

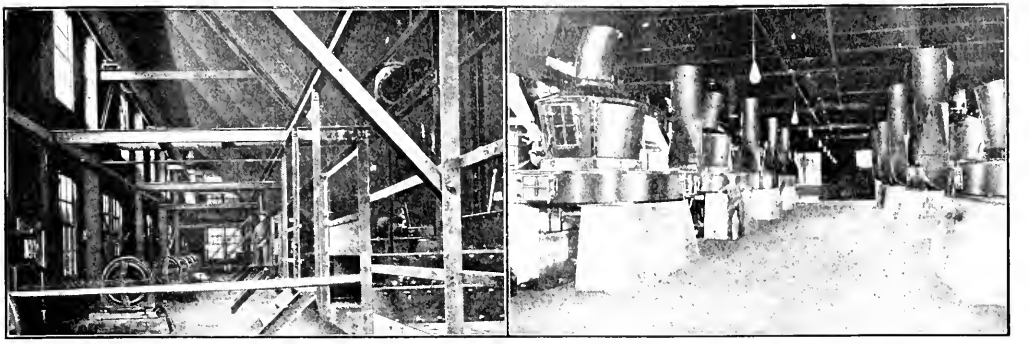
The Warford burners are illustrated in an accompanying drawing and may be described as follows: The feeding device, or control, consists of a screw conveyor inclosed in a cast-iron dust-tight housing which is bolted to the bottom opening of the hopper through which the coal dust is fed by gravity. The screw carries the coal dust forward to the discharge end of the conveyor housing, where it is discharged into four receiving pipes through a long slot; and what does not pass through the slot passes over and drops, through a larger opening at the extreme end of the conveyor housing, on the nozzle in the mixing chamber.

The mixing chamber consists of an outer housing, through which the blast-air nozzle extends. The coal dust



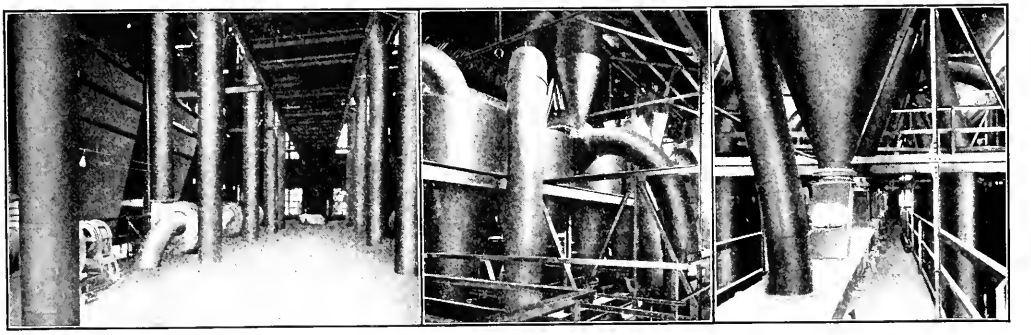
Warford Pulverized-Coal Burner

trol by the operator. These burners are susceptible to close regulation so as to burn any quantity from 5 to 26 tons of pulverized coal in 24 hr.



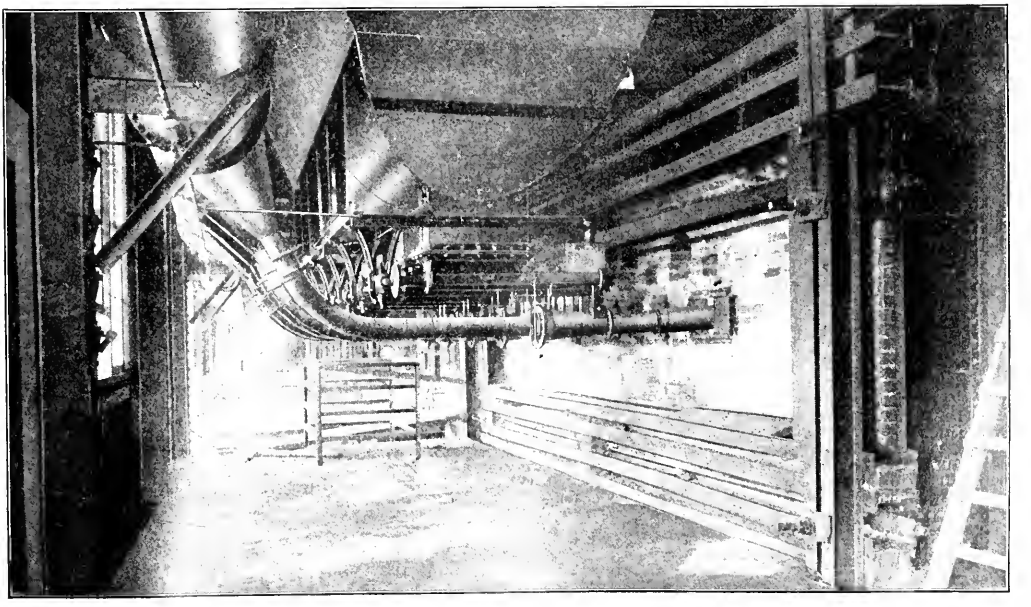
RAYMOND-MILL SECTION OF ANACONDA COAL-PULVERIZING PLANT

There are 10 Raymond mills, each 7 ft. 6 in. in diameter. The discharge from the pulverizing mills is controlled by fans which draw away the coal particles as they become fine enough to be acted upon by the suction



THE COAL-DUST COLLECTING SYSTEM

At the right are the fans that control the discharge from the Raymond mills. The other views show the Cyclone dust collectors and their discharge into screw conveyors delivering to the furnace bins



FIRING END OF REVERBERATORY, SHOWING WARFORD COAL BURNERS

The blowers used to supply air to the burners are two of the Sirocco type, made by the American Blower Co., each having a capacity of 10,000 cu.ft. of free air per minute, and six single-stage centrifugal compressors, manufactured by the General Electric Co., each of these also having a capacity of 10,000 cu.ft. of free air per minute. All of the blowers work on a pressure of 16 oz. and each is driven by a 75-hp. induction motor, direct connected.

The capacity of the pulverizing plant is 1200 tons in 24 hr. The crushers have a capacity of 1200 tons in 8 hr., the intention being to do all the crushing on day shift. The entire plant is designed to be as nearly automatic as possible, and all machinery through which the coal passes is made dustproof, so that but little dust is seen in the pulverized-coal department.

Possibility of Iron Smelting in Norway

SPECIAL CORRESPONDENCE

The Norwegian *Teknisk Ukeblad* in an article on iron-ore smelting in Norway says that England, Belgium, France and Germany will, after the war, require a colossal quantity of every sort of metal and that the demand for iron will increase enormously. The iron works of these countries using foreign ores will, in addition to the cost of the ore, have sea or canal freights and railway rates to meet, expenses which would be avoided by home treatment of a country's products. As regards coal for a Norwegian smelting enterprise, transport from Spitzbergen or England only would be necessary, and in the latter case the transport cost would be small, as the coal would be brought as return cargo by ore boats. The object to be attained is the reduction of Norwegian ores in Norway to as wide an extent as possible. Exporting its crude ores, as Norway is at present doing, is from an economic point of view unsatisfactory, as the labor employed in reduction is lost to the country and it is dangerous to be too dependent on other nations.

Norway possesses much of the world's best iron ore, including the Sydvaranger briquettes, which have a 65% Fe content. Excellent Swedish ore can also be purchased at reasonable prices. These ores are, however, too rich to be employed without the addition of lower grades, and the latter kind Norway possesses. The necessary limestone for slag purposes is available, together with magnesia- and lime-containing materials for furnace construction, and at a low cost. There are, moreover, plans under way for a large output of coal from Spitzbergen and a coke works in northern Norway. Hence the *Teknisk Ukeblad* asks:

> Why not take up our blast-furnace industry again? We have no time to wait upon electric smelting. The electric coke smelters, despite all reports as to favorable results, are as yet an unsolved problem in Norway. On the other hand, the ordinary blast furnaces, developed and proved throughout centuries and now in operation in most places with coke as a reduction material, are, of their kind, almost technically perfect. There has always been an established rule that the ore shall be brought to the fuel, and this has up till now practically held good. Lately, however, it appears that in large, new, mineralized districts it has been the custom to convey the fuel to the ore, and here iron works have been developed relatively more quickly than in the fuel districts.
>
> Broadly speaking, it is calculated that one ton of pig iron requires one ton of coke. Ore ought to be comparatively cheap wherever a blast furnace be operated in northern Norway. For instance, a site near Narvik would be particularly favorable, though there is no reason why it may not be selected even farther north. One should not be too anxious as to the amount of the output. It is apparent that the demand for iron has considerably increased even in our times. From 1870, with a requirement of 18 kg. iron per inhabitant, the consumption in Norway was in 1900 about 53 kg. per inhabitant. In Germany in 1900 it was already over 100 kg. per head. One should not commence with a lesser operation than 100,000 tons of pig iron yearly. Of that quantity about 50,000 tons might be marketed as foundry iron and the remainder refined on the spot by steel works. As regards a market, one must first reckon on Norway, and afterward on Sweden, Russia, Finland and Denmark. For a blast-furnace production of 100,000 tons of pig iron per annum, one-half of which is to be converted into steel, there would be required possibly a capital of 6,000,000 to 7,000,000 kroner ($1,600,000 to $1,875,000). It will be a big undertaking, but one for the benefit of the country and its independence. It will bring money into the country; it will provide a livelihood for Norwegian workmen and officials; and Norway will be self-supplying as far as iron is concerned.

The bulk of the capital employed in mining, as in most other undertakings in Norway, is foreign, and in special iron-ore propositions as at Sydvaranger and Dunderland, it is international, or British. If, after the war, it should prove to the interests of these concerns to continue their policy of exporting to British, German and French smelters, the only alternative, says the *Teknisk Ukeblad* (apart from the purchase of Swedish ores and state-aided mining propositions), would be a prohibitive export duty.

Do Nickel Minerals Underlie Cuban Iron Ore?

Several years ago C. K. Leith and William J. Mead contributed to the *Transactions* of the American Institute of Mining Engineers an account of the lateritic alterations of serpentine in eastern Cuba that produced the Mayari and Moa iron deposits. These authors at the San Francisco meeting will submit some additional data on the mineralogical changes from the serpentine rock below to the lateritic iron ore above. Twenty-nine analyses, supplied by chemists of the Spanish-American Iron Mines Co., representing a graded series from unaltered serpentine to the ore at the surface, were compared by means of the "straight-line diagram" with the analysis of the unaltered serpentine.

Starting with the unaltered rock, it was apparent that magnesia and silica were rapidly lost, magnesia practically disappearing at a distance of 5 ft. above the serpentine rock and silica being reduced to its minimum at about 10 ft. Alumina, iron and chromium rapidly increase with loss of the silica and magnesia. At about 10 ft. from the surface, the alumina shows an increased concentration. Nickel and cobalt are lost relative to iron and alumina, the loss being sharply accelerated at about the same depth at which a sharp acceleration in the relative increase of alumina occurs.

The marked loss of nickel and cobalt during the formation of the ore suggests the possibility of secondary downward concentration of these metals. Descriptions of the nickel ores of New Caledonia indicate that they are the result of alteration of peridotic and pyroxenic rocks and of serpentine rocks derived from them, from which the nickel is leached during weathering and carried down and deposited as hydrated silicates in veins in the underlying unaltered or slightly altered rock. This suggests the possibility of similar occurrence of secondary nickel-bearing minerals in the serpentine rock beneath the Cuban iron-ore deposits.

The Cost of an Ounce of Gold

By Percy E. Barbour

The cost of producing a pound of copper is commonly known and is nowadays almost never omitted from the annual report of any prominent copper-mining company. The cost of producing an ounce of gold is not only not commonly known, but is not included in the report of any gold-mining company which has ever come to the notice of the writer. The reason for this is obvious. Gold is generally, although erroneously, considered as money, and the mental attitude of the casual observer is that the gold-mining company is producing money, and no thought is given to the unit cost; and what is worse, to the unthoughtful observer, producing gold is all profit.

An investigation of the costs of operation per unit of gold recovered, in a large number of operations in various parts of the world, reveals some interesting figures which certainly furnish food for thought.* In classifying these gold-mining operations, we do not find that the type of deposit, or the locality, or the scale of operation has any specific or predominating effect on the cost of producing an ounce of gold.

Referring to the accompanying table, it will be noted that in the dredging operations in the Yukon, California, and Colorado, the cost of producing an ounce of gold is lower on the whole than is shown for other operations by the rest of the table. However, not only are the data of dredging operations enumerated in less number, but there are an equal number of low-cost producers in the other types of deposits mentioned.

PRODUCTION COSTS PER OUNCE AT SOME OF THE WORLD'S LEADING GOLD MINES

Location	Name of Mine	Year	Grade of Ore per Ton[1]	Production[2]	Cost of Gold per Ounce
Alaska	Alaska Treadwell	1912	$2.45	$2,183,150	$11.85

	Dawson Hydraulicking	....	21.19[5]	629,043	9.13
	Iditarod Dredging	1912-4	1.47[5]	1,971,091	7.69

[1]Yield per ton unless otherwise stated. [2]Includes miscellaneous small incomes. [3]Value in dollars per yard. [4]Dredging operations. [5]Value in cents per yard. [6]Gross value per ton.

If we look first at the large low-grade deposits of gold ore, taking the Treadwell in Alaska and the Homestake in South Dakota, we find their costs per ounce of gold produced are $11.85 and $13.72 respectively. These are close enough together so that we might assume that they are typical of unit costs in this type of deposit. However, many of the figures for other producers in more difficult orebodies, with less local advantage, and with operations on a smaller scale, show lower producing costs than do these two companies. Therefore, although these two companies produce upward of two and six million dollars respectively per annum, and work ore that averages $2.45 and $1.02 respectively, we see that operations on this scale do not necessarily make for low-cost productions per ounce of gold.

Furthermore, the Treadwell mines a lower grade of ore and is less favorably situated than the Homestake, yet has the lower production cost.

If we consider only those mines treating ore under $5 in value, we find the cost varies between $11.85 and $19.33. Looking at these figures again we see that three of the five producers in this class are small ones. It is, of course, perfectly reasonable that small productions should result in relatively higher production costs, but it is not an opinion which would be given offhand by the average man who considers that gold is gold and it matters not whether it is produced in large quantities or small.

Looking now at those companies treating ore of value between $5 and $10, we have five with production costs varying from $11.22 to $16.15. The $16.15 producer is the Round Mountain Mining Co. and mines an ore valued at $6.24 per ton. The production cost evidently reflects both the low-grade of the ore and adverse desert conditions at Round Mountain. Eliminating this one, we have four producers with costs between $11.22 and $13.58, three of these being foreign mines and only one a United States mine. All are large operations, under widely different conditions, and no especial significance attaches to the closeness of the cost.

Comparing these two groups it will be seen that the range of the costs is about the same for both groups, although the limit of value of one is double that of the other.

If we now examine those mines whose ore runs between $10 and $20 per ton, we find eight in the table whose production costs range from $7.21 to $16.78. One mine in this class, the Abanagarez, produced its gold at a loss, its production cost being $25.01 per ounce. This case being an exceptional one, under the circumstances, we are omitting it from consideration in the figures and conclusions, but call attention to it to show that all gold mines are not paying propositions, even if their production is extremely large, as in this case where the annual production was over half a million dollars and the ore above $12 per ton.

Referring again to the table, we find no uniformity to support the too general conclusion. The Goldfield Consolidated has the lowest cost in this group, $7.21 per ounce, the next lowest being the Mysore of India, which has a cost of $8.39. The highest cost is the Abanagarez which we noted above, and the next one is $16.78 at the El Paso mine in Cripple Creek. If we take those mines whose ores run above $20, we have an even greater discrepancy in the producing cost, finding that one producer is as low as $7.65, while the other extreme is $15.94.

If we analyze these figures on the basis of total annual production, we find that for those whose production is less than $500,000 per year, the cost varies from $9.67 to $19.33. For those whose production is between one-half and one million, the cost varies from $8.39 to $25.01. For those whose production is between one and two million, the cost varies from $7.65 to $15.94. Considering those

*The U. S. Mint pays a fixed price of $20.67 per oz. for gold.

whose production is in excess of two million per year, we find that the cost varies from $7.21 to $13.72 per ounce.

The largest producer given in the list is the Witwatersrand, whose production is more than $165,000,000 annually, and its cost of production is $13.58. This is not nearly as low as would be expected, considering the size of the operation and the grade of the ore.

Nor does the company with the lowest grade of ore have the highest production cost, although as we have shown above, the figures indicate the natural expectation that with low-grade ore on small propositions and limited operations, the production cost tends to the higher limit.

The lowest cost in the list is from the Yuba dredging operations in California, and is $6.26 per ounce. Outside of the dredging operations, the lowest cost given in the table is the Goldfield Consolidated for the year 1912, when it produced gold at a cost of $7.21 per ounce. During 1914 the corresponding cost was $11.93, and the average values of the ores for the two years were $19.97 and $12.57 respectively. During 1912, the Camp Bird produced gold at a cost of $7.65. There is a balancing of advantageous and disadvantageous circumstances in these cases which bring the ultimate producing costs so close together, but under widely divergent conditions the Mysore produced for $8.39, a not greatly different cost.

These figures dispel many illusions. Cheap Kafir labor in the Transvaal, coupled with operations on an enormous scale in ore of fair average grade, and under conditions otherwise reasonably favorable, does not by any means give the lowest production cost. Neither does the lowest-grade ore under disadvantageous circumstances give the highest cost of production.

Therefore it is evident that neither the grade of the ore, the locality of the mine nor the size and extent of the operation have a predominating effect upon the producing cost of an ounce of gold.

These figures should show also that producing gold is not all "velvet." None of these figures quoted takes into consideration any of the enormous investments in plant and equipment which are required for this production. Not only do these figures not contain any amortization, but they do not include any interest on the principal. So few companies follow any broad-gage method in this respect that these two factors cannot be taken into consideration in the figures, and in any event, those companies which do write off annual amounts for the sinking fund, have no uniformity of method, and for that reason also it is impossible to include that factor in these comparative figures.

It is, therefore, also evident that the old expression, "a regular gold mine," which is supposed to indicate an ultra-profitable venture, is a misnomer, and that producing gold, even under the best conditions, is often a pretty tough proposition.

Tungsten in the British Empire

One of the industries, formerly carried on chiefly in Germany, which have been established in Great Britain since the outbreak of war is the refining of tungsten, says the *Chemical Trade Review*, quoting from the *Chamber of Commerce Journal*. From the moment of the outbreak of war, the establishment of this industry was of the most importance, in view of the requirements of the factories engaged in the production of armaments. The British Government was not unwilling to assist in founding a tungsten refinery, but steel manufacturers realized that the control which the Government would have properly desired to exercise if public money had been provided, and the fact that the output of the refinery would necessarily have to be sold under certain restrictions, rendered it desirable to dispense, if possible, with such assistance in order that the entire control of the new industry might be in their hands. The steel manufacturers found themselves strong enough to do this, and the refinery is now in operation.

Burma is now the world's largest producer of tungsten ores, the other chief sources being the United States (1390 tons in 1913), Portugal (1380 tons in 1913), South America (Peru, 300 tons in 1913; Argentina, 638 tons in 1912; Bolivia, 497 tons in 1912), and Australia. There is also a small output in Spain, Japan, and the United Kingdom.

The production of tungsten ore in Burma dates only from 1910, when 395 tons were mined, rising to 1671 tons in 1912. The production in 1913 is recorded, unofficially, as 2700 tons. Most of the ore is mined in the Tavoy district, Mergui produces a smaller quantity, and the remainder comes from the Southern Shan States.

The following are some details of the production of tungsten ores, the chief of which are wolfram and scheelite, in other parts of the British Empire:

The production of wolfram in Queensland in 1913 was 359 tons, value £35,359, as compared with 626½ tons, value £57,821, in the preceding year. In addition, 182 tons of "bismuth and wolfram," value £17,867, were mined in 1913, as compared with 191½ tons, value £16,426, in 1912.

The quantity of scheelite exported from New South Wales during the year 1913 amounted to 44 tons, valued at £4457, as against 56 tons valued at £4963, in 1912. The mineral is obtained in the vicinity of the town of Hillgrove. The mineral is found chiefly in patches or pockets. The quantity of wolfram exported from New South Wales during 1913 amounted to 126 tons, valued at £13,037, as compared with 172 tons, valued at £16,584, in the previous year.

The quantity of scheelite concentrates exported from New Zealand during 1912 amounted to 135 tons, valued at £13,347, being a slight increase (as regards value only) over the output during the previous year. This mineral is usually obtained in conjunction with auriferous-quartz mining in Otago and Southland, but during 1912 a quartz-scheelite mine of some magnitude was opened at Wakamarina Valley, Marlborough. The output of wolfram ore in Tasmania in 1913 was 68 tons, value £7040 chiefly from Avoca and from Shepherd and Murphy Mine at Middlesex. The production of wolfram in Victoria, Australia, in 1913, was only 12 cwt., worth £49.

The occurrence of tungsten ores in economic quantity in Canada is confined to a few small areas, the most important of which is situated in Halifax County, Nova Scotia. Operations have been under way on these deposits for two or three years, and one firm is now turning out satisfactory high-grade concentrates. New finds are constantly being made in this district, which promises to become an important producer. In Lunenburg County, Nova Scotia, scheelite, cassiterite, and molybdenite have been found together at a point some three miles east of New Ross, and some high-grade hübnerite, another ore of

tungsten, is to be seen near N.E. Margaree, Inverness County, Cape Breton.

Several tungsten minerals have been obtained in British Columbia, more especially near Salmo. The gold ores of the Kootenay Belle and Queen mines, on or near Sheep Creek, carry an appreciable amount of tungsten, some of which is recovered with the concentrates from the gold mills. At the Meteor mine, in the Slocan district, scheelite has been found. The best of the Western prospects seems to be one situated on Willow Creek, 10 mi. northwest of Barkerville, in the Cariboo district.

Recent statistics of the output of tungsten in Canada are not available. In 1912, 14 tons of concentrated scheelite ore (72% tungstic acid) were shipped, and the shipments for 1913 are stated to have been considerably larger.

As regards the United Kingdom, wolfram ore is mined at Illogan and Carn Brea in Cornwall, the production in 1912 amounting to 193 tons, valued at £16,873.

Russian Mining Laws Protect the Worker

By Leonard C. David*

The rights of employer and employee in the Russian Empire are clearly defined by laws which are strictly enforced. The government's interests in each mining district are looked after by an engineer of experience. He has at each industrial plant or mine one or more "steigers" who have passed examinations for such work and who in reality are government superintendents, responsible to a district engineer for the safety and sanitation of the works.

In case of an accident, the first on the scene are generally the police; and the "priestoff," who is the local chief of police, makes out a protocol or statement based on first-hand evidence and if possible blames the steiger or some other individual for neglect. The steiger makes a protocol also, and these two protocols go to the district engineer, who goes to the scene of the accident, makes out a protocol of his own, and on the basis of his conclusions the government starts suit for the injured person. It has often happened that the steiger or some other person has had to serve a sentence in jail for neglect of duty, as specified by the Russian mining law.

In hiring men, the law requires that all applicants shall pass a rigid physical examination by the doctor or his "feldsher." The feldsher is a man trained in first-aid work as well as in pharmacy, and such men are valuable around industrial plants. For the first six days, a new man is on trial and can be discharged without notice. After six days he becomes a regular employee and cannot be discharged without 14 days' notice, or he can be immediately discharged and paid for 14 days of work. The Duma recently passed a workingmen's compensation or insurance law which provides for a fund contributed mostly by the companies. In case of illness or injury an employee receives half of his wages from this fund. The employee contributes each month 2% of his wages toward this insurance.

The interest in these stipulations is due to the usual assumption that the welfare of the Russian wage-earner is a matter little considered by his government and its lawmakers.

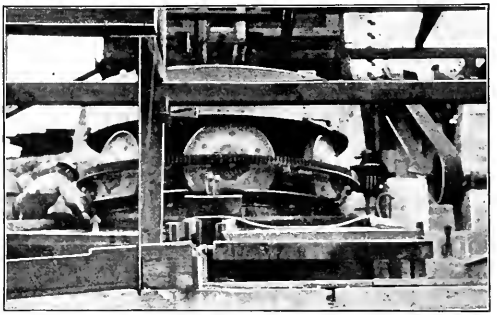
Milling Below Sea Level

By Lewis H. Eddy*

The milling plant of the McCausland mine in the extreme southern end of Death Valley, California, stands at a point 150 ft. below sea level. The mine is on the rim of the valley at an elevation of 2250 ft. above sea level and four miles from the mill. The ore is hauled from mine to mill on motor trucks. This is probably the lowest point at which milling or other metallurgical operation is carried on in California or in the Pacific Coast region. There are ranches below sea level and there is a large amount of travel across and through Death Valley at minus elevations. But usually the mines in this region



Lane Mill at McCausland Mine, California

are so situated that the treatment of ores may be carried on at points above sea level, and generally within the area of the mining ground. The McCausland mine stands at a comparatively low point, although there are mines in neighboring regions as low or lower, but the topography here is so precipitous that the floor of Death Valley offers the only point within reasonable distance for the installation of the mill.

So much has been written and told of the terrors of Death Valley and the hardships of desert mining that probably few people, unacquainted with the topographic and climatic conditions of the desert regions, believe it possible to labor below sea level. There are places where it is not possible to labor or to live without suffering great discomfort, and they are not confined to Death Valley nor to even sea level. The chances are better at the mill camp of the McCausland mine than in the center of Panamint Valley at an elevation of 1000 ft. It is not so much the proximity to sea level that one need fear as the distance and elevation of the surrounding mountains and the absence of water. At the McCausland camp, as at Furnace Creek ranch, one is in the shadow of the mountains. In the broader expanses of Death Valley and of Panamint Valley there are no shadows.

The McCausland mine and milling plant are situated about 30 miles west of Zabriskie, in Inyo County, a shipping station on the Tonopah & Tidewater R.R., three miles north of Tecopa. Machinery for mine and mill was shipped from Los Angeles via the Santa Fé Ry. to Ludlow, thence via the Tonopah & Tidewater to Zabriskie, and hauled in on motor trucks over fairly good roads. The metallurgical equipment consists of a 10-ft. Lane mill,

*Associate editor, "Engineering and Mining Journal," San Francisco, Calif.

8x16-in. Samson crusher, Hammil elevator ore feeder, grizzly, amalgamating plates and Wilfley concentrating tables. It is driven by a 32-hp. Fairbanks-Morse distillate engine. The Wilfleys were taken out of commission after trial runs showing that concentration was not essential.

Prior to installation of the plant, laboratory amalgamation tests showed possible recovery of 57% of assay values by amalgamation. On this account the concentrators were installed. Practical operation of the mill, treating 40 tons per 24 hr., gave 93 to 96% of assay value by inside amalgamation alone after an improvement, fashioned by the mill superintendent, had been installed. This device consists of raised beads forming riffles placed diagonally across the mill plates, which assist in building up amalgam on the plates by protecting it from the action of the current, the amalgam forming mainly behind the raised beads. This improvement while aiding amalgamation is not claimed to be wholly responsible for increasing recovery, but it took the place of the concentrators. The discharge product is fine, 72.51% passing a 100-mesh screen and 53.42% passing a 200-mesh screen. The ore is at present of more than average hardness. The property is owned chiefly by B. W. McCausland and is not incorporated. R. D. McCausland is mine superintendent and Alexander McLaren mill superintendent. The milling plant was built and installed by the Lane Mill & Machinery Co., 236 Douglas Building, Los Angeles.

Absorption of Gases by Refined Copper

The gas-absorbing power of molten copper increases in general with the temperature up to a certain point, also with increasing purity of the metal, and with the partial pressure of the gas; the presence of Pt or Ni, however, has a favorable influence on the absorption, according to W. Stahl in *Metall und Erz* (abstr. *Journal* Soc. Chem. Ind., Dec. 15, 1914).

The disintegration of copper which takes place during solidification has been traced to occluded SO_2, which is formed by oxidation of the sulphur present, and given up during solidification with a "spitting" action. Up to 1500°, the absorption increases almost linearly with the temperature and approximately as the square root of the pressure. The fact that the gas causes the metal to "spit" and become spongy during solidification, and that a considerable quantity of gas is still retained in the cold metal, shows that absorption and not adsorption effects are concerned. SO_2 does not diffuse through solid copper below 1000° C. The interaction of cuprous oxide and sulphide, giving copper and sulphur dioxide, is exothermic; the reverse reaction can be expressed as $Cu_2S + 2\ Cu_2O = 6\ Cu + SO_2 - 38{,}000$ cals. It follows from this that an equilibrium relation will be obtained. Estimations of the lowering of freezing point produced by the oxide and sulphide show that the compounds occur as Cu_2S and Cu_2O, and that their solubilities are more than sufficient to account for the absorption of SO_2 by decomposition and chemical reaction. The fact that the addition of either Cu_2S or Cu_2O to the system diminishes the solubility of the gas is also in accord with this view. That a state of equilibrium between the four participating bodies occurs at all temperatures has been verified in a number of investigations.

Evidence of the solubility of hydrogen is given by the surface disintegration and blister-like structure assumed by the metal during solidification after exposure to this gas. An absorption of H_2 in, and diffusion through, copper has been detected at 650° C. Up to 1500° C. the absorption increases almost linearly with the temperature, except at the melting point of the metal when a sudden increase occurs. At 650° the solubility is 0.1 and at 1500° C., 1.4 mg. H_2 per 100 grams of copper. With both the molten and solid metal, the solubility increases as the square root of the pressure. The conductivity of copper is not affected by dissolved hydrogen. On heating copper containing oxide in a hydrogen atmosphere, the gas penetrates the metal and reduces the oxide with formation of water, which escapes by disintegrating the metal and rendering it unsuitable for further mechanical working. A reaction of this nature takes place in molten copper during the "poling" treatment.

Hydrocarbons are decomposed by molten copper into carbon and hydrogen, of which the former is oxidized and the latter absorbed. No occlusion of any undecomposed hydrocarbon has been observed.

The dissociation pressure of cuprous oxide equals the partial pressure of atmospheric oxygen, or 0.21 atmospheres, at 1662° C. When in solution in the copper, the dissociation pressure is lowered so that at 1600° C. it is certain that no thermal decomposition of the dissolved oxide occurs, and the absorption of O_2 at this temperature is not a physical solution but a chemical combination.

With water, carbon-dioxide, nitrogen, argon or helium gases no absorption by either solid or liquid copper can be detected. A slight solubility of carbon monoxide has been shown by changes in the density produced in the metal by its presence, by the blister-like structure it imparts to the metal, by spectrum analysis, and by direct measurement. At 1120°, 61 grams of Cu absorb 0.15 c.c. CO. This small quantity of gas appears to have a marked influence on the physical properties of the refined metal.

The above data indicate that during the refining of molten copper, the absorption of CO predominates during the end of the "hard poling" period and at the beginning of the "green poling," while the absorption of H_2 predominates during the latter period when the oxygen has been removed.

Duty to Warn Mine Employees

In exonerating a Missouri mining company from liability for fatal injury to a shoveler in a mine, received while attempting to explode a stick of dynamite in breaking up boulders the second day of his employment, the Springfield Court of Appeals holds that an operator of a mine is under no legal duty to warn an employee against an ordinary danger of his work, unless the operator has actual or constructive knowledge that the employee is inexperienced in that line or work; than an employer is entitled to assume that an adult applicant for a given position is competent to perform the work of that position; and that an inexperienced employee is guilty of contributory negligence in attempting to use dynamite in breaking boulders, merely because others in the same employment are permitted to do so. (Batesel vs. American Zinc, Lead & Smelting Co., 176 *Southwestern Reporter*, 446.)

Shaft-Rockhouse Practice in the Copper Country—IV

By L. Hall Goodwin*

SYNOPSIS—Quincy rockhouse system complicated because of necessity of handling much mass copper. Copper Range system extremely simple. Quincy employs elaborate methods to handle mass. Copper rock fed to crusher by use of chute with gate at each end. Quincy crushers use broad corrugations. Two methods of loading stamp rock. Copper Range uses no grizzly, passing all rock through crusher. Comparisons of methods are vain.

The rockhouse methods taken up in this installment are those used by the two largest companies in the district not controlled by the Calumet & Hecla interests.

The Quincy System

The flowsheet of Quincy No. 2 rockhouse which T. C. DeSollar presents in his paper describing that building, read before the 1912 meeting of the Lake Superior Mining Institute,[1] shows, I believe, a more complicated arrangement of working parts than would a similar diagram of a rockhouse of any other mine in the district, and this is largely true because this company's rockhouse problems are increased by the large proportion of mass copper in the Pewabic lode.

The term mass copper is used rather loosely to cover all sizes of the native metal as it occurs in the rock, from small nuggets up to huge masses weighing many tons. A distinction is sometimes made by referring to those sizes ranging from, say, 50 lb. down to fist size as "barrel-work," a term derived from the old custom of sending masses of this size to the smelting plant in barrels. At the different mines in the district the occurrence of mass copper differs in the proportion it bears to the stamp copper in the vein. At some mines it is of rather slight importance; at others it forms a considerable percentage of the total output. Among the bedded veins, which at present are the only ones worked, it appears that the mines near Portage Lake, Quincy, Isle Royale and Hancock, have a larger proportion of mass than the others.

Handling Mass Copper

Thus Quincy practice in handling mass copper is more highly developed than that of any other mine, and while a description of its methods will not be exactly typical of those of the district, it will cover the subject more fully than a like description of any other method. Fig. 16 shows diagrammatically the sequence of the principal processes involved in the segregation of the mass copper from the copper rock and the disposition of those two products. The fine rock which will pass the grizzly and all rock which has been crushed are here referred to as "stamp rock."

Masses so large that they will not go into the skip—and there are many such—are cut underground by means of a pneumatic chisel into pieces small enough to hoist. These pieces, as well as those single masses weighing from a few hundred pounds up, which do not need to be cleaned of the rock adhering to them, are hoisted in the regular rock skip, but are not mixed with copper rock and are not taken to the rockhouse proper, but are dumped automatically into the shafthouse just above the collar of the shaft upon a concrete chute. This is faced with old rails to protect the concrete from rapid wear by the jagged edges of the heavy mass copper. This chute delivers the masses to a platform at a convenient height for loading on railroad flat cars, on which they are shipped directly to the smelting works. Masses weighing up to eight tons are loaded on the cars by means of chain blocks hung from trolleys carried on heavy I-beams which extend over the track.

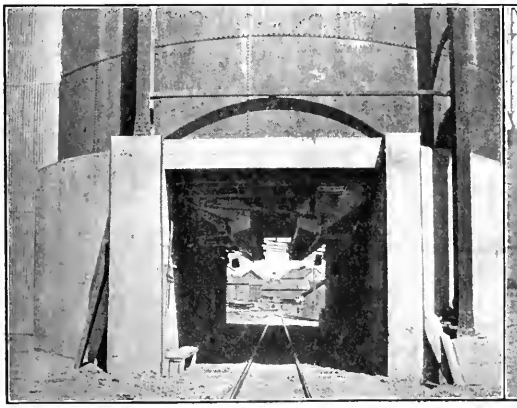


Fig. 12. Quincy Method of Loading Stamp Rock

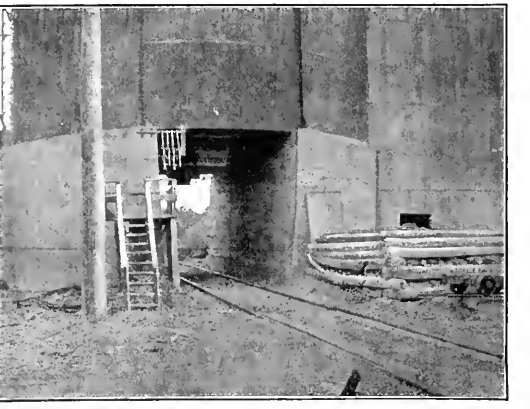

Fig. 13. Usual Method of Rock Loading

*Assistant with Allen H. Rogers, 201 Devonshire St., Boston, Mass.

[1]"Proceedings" of the Lake Superior Mining Institute, p. 217, 1912.

Smaller masses, and larger ones up to a ton or more, which need to be cleaned under a drop hammer before they can be shipped, are dumped into the skip underground along with the copper rock. At other mines no attempt is made to separate these masses from the copper rock mechanically. They are simply picked out before the rock is fed to the crusher; at the Quincy, however, a set of 6-in. round grizzly bars, 16 ft. long, sloping at 16° and having 20-in. spaces, is placed over the copper rock grizzly so as to take off the larger masses, as well as large pieces of copper rock which have to be broken by the drop hammer before being fed to the crusher. These wide-spaced grizzly bars deliver the masses to a chute, which conducts them over a working part of the crushing floor to a bin at the extreme side of the building. This bin is rectangular, one side of it being entirely open and facing a 3000-lb. drop hammer. An air lift is used to handle the masses, which are placed under the hammer and pounded, a few blows usually being sufficient to render them fairly free from adhering rock. They are then placed on a heavy iron pan which swings from a crane to clear the sides of the building, and are lowered to a platform outside, from which they are readily removed to railroad cars.

Those masses which are too small to be removed by the 20-in. grizzly go into the hopper bin along with the copper rock and are later separated from it by the crushermen, who pick it out by hand or with the aid of the air lift as it goes through the chute from the hopper bin. It is important that all of the mass be picked out, as it does not require a large piece to cause great trouble between the jaws of the crusher. These masses are piled up on the "copper pan," a semi-circular steel chute set at a slight inclination, at the lower end of which is a small steam hammer. The copper pan is situated between the two crushers so that it may be easily reached from either of them. The barrel-work copper is left piled up on it until the man whose duty it is gets around to clean it; it is then thrown into a chute leading to the mass-copper bin. This small steam hammer does the work of cleaning the barrel-work quickly and effectively and is an important adjunct to all Quincy rockhouses. So far as I know it is not used elsewhere in the district.

Handling Copper Rock

Under the widespaced grizzly is a smaller one with 3-in. spaces. Undersize from this grizzly goes directly to the stamp-rock bin, oversize to the hopper bin, a cylindrical steel bin having a capacity of about 10 skip-loads. Two openings set radially in the sides of the hopper bin at its bottom lead to chutes which feed two 24x36-in. crushers. The chutes are about 5 ft. long and are set at 30°. Feed to them is controlled by a heavy iron gate sliding vertically to close the opening in the hopper bin; feed from them is controlled by a sort of flap apron, hinged along the bottom edge of the chute, which swings upward in an arc to close the chute and is operated by an air cylinder.

The operation of feeding rock to the crusher is as follows: The chute being empty, the apron at its end is raised to prevent the rock from going to the crusher, the bin gate is lifted and the rock allowed to run out until the chute is full; then the bin gate is allowed to close by gravity and the mass copper and waste are picked out; the chute apron is lowered and the rock is allowed to feed to the crusher; when the chute is empty the operation is repeated. Of course in practice the method works faster than this description would indicate, both gate and apron often being open at the same time.

Power is furnished by a corliss engine on the crusher floor, and a motor of corresponding capacity is always held in readiness to assume the load should anything happen to the engine.

Fig. 15 will serve to illustrate the general features of the design of the Quincy No. 2 shaft-rockhouse and to make clear the preceding description of its rock-handling methods. As stated in Part I, this building may be viewed as typical of a broad class of modern shaft rockhouses in the Lake Superior district.

Advantages and Disadvantages of Method

As has been stated, this process is complicated and the rockhouse work is increased, compared with most other mines of the district, by the large amount of mass copper handled. The crushing floor occupies a space only 44 ft. square, and the effective arrangement of the machinery in this limited space enables a large output to be handled by only three men per shift, one of whom attends to the machinery and cleans most of the mass copper. The hopper bin furnishes a small storage capacity, which enables hoisting operations to be continued for a while after any accident has happened, and it also enables all three of the rockhouse men to work for short periods at operating the drop hammer, etc. A disadvantage of the method would appear to be that the grizzlies, located as they are at the top of the hopper bin, are out of sight of the men on the crusher floor and are not easily reached to be cleaned. At the North Kearsarge No. 4 rockhouse of the Osceola Consolidated, which uses the Quincy system, this difficulty is eliminated by having the lander stationed near the grizzly, and it is one of his duties to clean down the grizzly each time after a skip has dumped. This method would not be applicable at the Quincy, however, as the lander is an important man in the shafthouse end of the building.

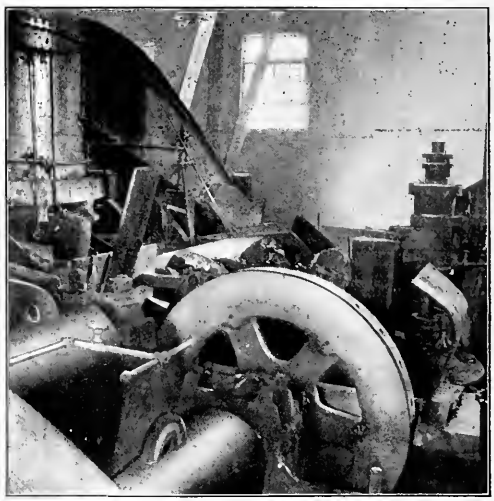

Fig. 14. Crushing Floor at the Quincy

Details of Quincy Crushing

Quincy crushers, Fig. 14, are operated at the low speed of 140 r.p.m. presumably because of the comparatively soft amygdaloid rock handled. It appears to be a rule that the hardness of the rock governs the speed of the crusher. The Calumet & Hecla, where it handles the hard conglomerate, uses about 175 r.p.m., and the Copper Range mines, on their dense amygdaloid, use as high as 185 r.p.m.

Crusher jaws at the Quincy have wide corrugations, 1 ft. between the tops of adjoining ridges. Some mines use narrow corrugations ranging down to 2 in., and it has already been noted that the Calumet & Hecla uses smooth jaws. Various ideas are held as to the virtues of corrugations, but later practice seems to tend toward avoiding them entirely, since they retard the discharge of rock and make it more difficult to extract masses from between the jaws. The broad corrugations at Quincy, however, appear to have distinct advantages, and they are so wide that the disadvantages of the usual corrugations are largely avoided. A large boulder, which would bear fairly evenly over a considerable area of a flat jaw or on many of the small corrugations of the usual type, will bear at, say, four points only, corresponding to its contact with two ridges on either jaw. This has the effect of confining the breaking at first to a few points, and the strain on the crusher is much less.

Quincy jaws are made of manganese steel, which is the usual practice throughout the district. The Calumet & Hecla uses this material at the conglomerate rockhouses, but uses chilled cast iron for the amygdaloid, presumably because it has facilities for casting the iron jaws, which, however, would not be suitable for crushing the hard conglomerate. For the softer rocks the chilled iron is quite as good as manganese steel, its only disadvantage being that the chilled surface is likely not to be uniformly hard and the jaws wear unevenly.

Loading Stamp Rock

The Quincy method of loading stamp rock from the main storage bin into cars for transportation to the mill is unique in the use of air cylinders for operating the chutes and also in the arrangement of the chutes. These are placed in pairs opposite each other on each side of the railroad track, and each pair is operated as one by a 3x15-in. air cylinder (Fig. 12). This arrangement of the chutes is good because there are more than twice as many of them as when there is a single row placed over the center of the track, which permits more rapid loading and draws the rock from a greater bin area; in fact, nearly the same result is accomplished in this way as is obtained by putting two tracks under the bin. The form of chute used is simple. It is closed by two aprons, of which the more important is hinged along the lower edge of the chute and swings upward in an arc to stop the flow of rock, while the other is hinged above the mouth of the chute and acts by gravity only.

That this method is not used elsewhere is probably due to the fact that at other properties the supply of air for rockhouse use is wholly dependent upon the underground

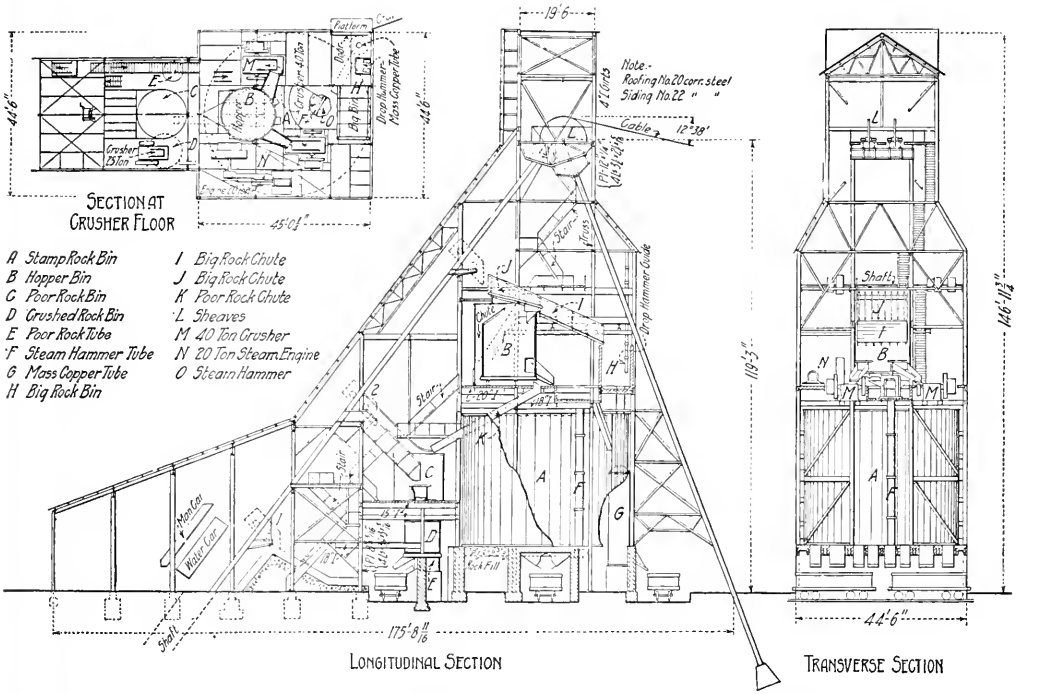

Fig. 15. Plan and Elevations of Quincy No. 2 Shaft-Rockhouse

air system, and when the main air compressor is stopped between shifts no air is available for rockhouse operations. The Quincy overcame this difficulty by installing at each rockhouse a small Westinghouse air pump, which is so regulated that it starts and stops automatically, depending on whether the pressure in the mains falls below a certain point or exceeds it.

The other important method of loading stamp rock is used almost exclusively throughout the district, except for the Quincy. The form of chute used is essentially the same as that just described, but the chutes are placed directly over the center of the track, and the levers operating them are worked by hand (Fig. 13). The important factor in comparing present practice with old is that the levers are controlled from a central point. At the Quincy there is a recess in the bin foundations large enough for a man to stand in and operate the air cocks; while at other mines the levers are operated from a platform at the side of the track, or between the tracks if

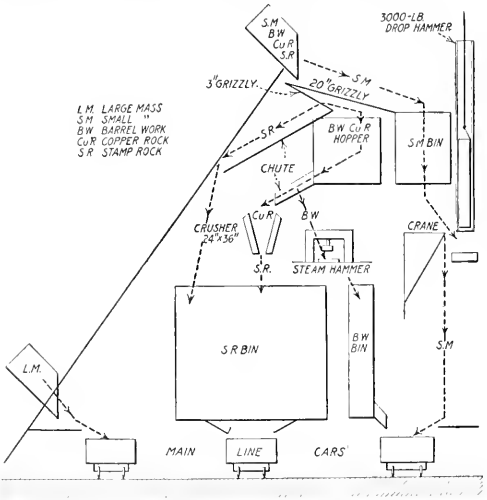

FIG. 16. DIAGRAM OF QUINCY ROCKHOUSE OPERATIONS

there are two of them. At many of the older rockhouses —such as those on the Calumet conglomerate and the Osceola amygdaloid in Calumet—there are two tracks under the bin, because the old rectangular bins were so large in horizontal section. Two tracks are still used, but for a different reason, where the bins are unusually large as at the new Ahmeek Nos. 3 and 4 shaft rockhouse.

Statements as to the speed with which a car can be loaded are often overdrawn. For instance, the claim has been made that at a certain plant using the usual method a 40-ton car can be loaded in 10 sec., which is perhaps true. However, after reading that statement, I found an item in my notebook regarding this shaft which stated that it required 13 min. for two men and a locomotive with its operators to load nine cars, which is probably nearer the actual working speed.

COPPER RANGE CONSOLIDATED SYSTEM

The method of handling copper rock used by the Copper Range Consolidated is unique among those of this district in that no attempt is made to remove the fine rock by a grizzly, all of it passing through the crusher. In other respects the method is much like that of the Quincy insofar as copper rock is concerned, although the smaller proportion of mass in the Copper Range rock makes its rockhouse problem much simpler than that of the Quincy.

The skip dumps directly into a large hopper bin with a capacity of about 25 to 30 skip loads. From there the rock is drawn off through two openings opposite each skip dump. The mode of feeding the crusher is exactly the same in principle as that at the Quincy, but the methods differ in details. The hopper bin instead of being of cylindrical steel construction is of wood, and of rectangular pattern. Steel is used sparingly about the bin. It is used in places where the wear on wood would be excessive and in a small space back of the bin door to provide a chute which aids in starting the rock through the door, the rest of the bin bottom being of the usual rock type. The bin doors are closed by vertically sliding wooden gates 5 ft. square, lined with 2-in. cast-iron plates. The lower end of the chute rests directly on the jaw of the crusher, and the chute is closed by an apron pivoted on a shaft on the top of the crusher and fitting into the lower end of the chute. This chute apron and the bin gate are operated by air lifts.

Mass copper is cleaned under a drop hammer and is then pushed through a door and allowed to drop to a platform, built of log cribbing filled with waste rock, alongside a railroad track.

The Copper Range method is minutely described in a paper[2] read before the 1912 meeting of the Lake Superior Mining Institute, and an interesting discussion of the development of the rockhouse practice of this company is given.

ADVANTAGES AND DISADVANTAGES

The great advantages of the system are its extreme simplicity and the small maintenance charges necessary to keep the rockhouse in first-class working condition. The regular crew consists of two men only, who handle a large output. The great capacity of the hopper bin enables hoisting operations to be continued while any ordinary breakdown in the rockhouse equipment is being repaired. The hopper-bin opening is made so large that the usual trouble experienced in getting the larger pieces of rock through that opening is largely avoided.

The natural criticism is that power is wasted in doing unnecessary crushing on the fine rock. This disadvantage is partly offset by the better crushing secured, and it has been found an advantage to have the stamp rock in the bin evenly mixed, as is the case where all the rock goes through the crusher.

I would not like to create the impression that the small space accorded to this system is a measure of its worth. The method is so simple that it does not require much description, and many details of its practice have been considered in other parts of this paper.

COMPARISONS OF THE SEVERAL METHODS

To those only superficially acquainted with Lake Superior mining it will perhaps seem that so wide a variance in rockhouse methods as is indicated by our preceding descriptions is not justified, and that it must necessarily follow that some of these four broad methods must be

[2] "Rockhouse Practice of the Copper Range Consolidated Company," by H. T. Mercer, chief engineer, "Proceedings" of the Lake Superior Mining Institute, 1912, p. 283

notably weaker than others. As a matter of fact, although the producing Lake Superior copper mines are located on the same type of bedded vein, of either amygdaloid or conglomerate formation, the rock from different mines needs different treatment in all departments—mining, milling and smelting. Another factor is that two different managements confronted by the same problems will work along entirely different lines and by close attention to the weak points of their respective systems so perfect them that a comparison of the two as regards their ultimate efficiencies must be made reservedly.

In comparing different rockhouses of the same mine, which serve shafts having about the same capacity and handle the same kind of rock, the ultimate analysis of rockhouse efficiency is found in the cost sheet. In this case figures do not lie. It would be not only useless but misleading, however, to compare figures of costs of the different companies' rockhouse operations, because that cost depends upon many factors which are widely variable at the different mines.

As a general proposition, the statement may be made that some of the most efficient rockhouses, serving shafts of large capacity and operating under favorable conditions, have shown over considerable periods an average rockhouse labor cost of 2½ or even 2c. per ton of material handled. This figure is probably much lower than the average cost in the district as a whole. The important facts in this connection are that costs have shown a steady decline for many years, and that according to figures recently published covering one of the important mines the unit cost of material handled was shown to have decreased approximately 50% during the last 10 years. Another important mine reduced its unit rockhouse costs nearly 70% in 12 years; and these economies, it must be remembered, were effected in the face of material advances in the price of labor.

In closing this series of articles I wish to extend my thanks to the general managers of the several properties, who were without exception liberal in extending courtesies, and also to those rockhouse superintendents, engineers and others who aided me, many of whom put themselves to a great deal of trouble to give accurate information.

Qualifications of Montana Hoisting Engineers

By A. L. H. Street*

Under the provisions of a law enacted at the last session of the Montana legislature, operators of electric- or air-hoisting engines of more than 25 hp., used in lowering or hoisting men in mines or other underground works, must obtain licenses renewable annually. Two classes of licenses are provided for, first- and second-class. Holders of the former may operate any hoisting engine covered by the law, as may first-class licensed engineers. Licenses of the second class do not authorize the operation of hoisting engines of more than 100 hp. The power to issue and revoke licenses is vested in the State Boiler Inspector. The act declares it to be a misdemeanor for an unlicensed person to operate hoisting engines covered by the law, or for an owner or manager to knowingly employ such person.

United States Bauxite and Aluminum Production

The production of bauxite and the consumption of aluminum in the United States in 1914 were the largest ever recorded. The report prepared by the Geological Survey shows an output of 219,318 long tons of bauxite in 1914, against 240,241 long tons in 1913. The states which produced bauxite in 1914 were Alabama, Arkansas, Georgia and Tennessee. Arkansas produced more than 80% of the output, owing to the extensive operations of the American Bauxite Co. in Saline County. The production of Georgia, which held second place in both years, and of Alabama and Tennessee was considerably less in 1914 than it was in 1913. The imports of bauxite amounted to 24,844 long tons, or 3388 tons more than in 1913.

Bauxite is used in the production of metallic aluminum (its most important use) and in the manufacture of aluminum salts, of bauxite bricks and of alundum. The commercial mineral carries 50 to 60% of Al_2O_3, corresponding to 26.5 to 31.8% of Al.

Alundum, which is used extensively as an abrasive, is made at Niagara Falls, N. Y., by fusing calcined bauxite in an electric furnace. Only the best grades of bauxite are used in the manufacture of such chemicals as alum, aluminum sulphate and aluminum salts, as freedom from oxide of iron is desirable for such purposes.

Another use to which bauxite is adapted is in the manufacture of calcium aluminate, which gives a quick set to plaster compositions.

The quantity of aluminum consumed in the United States in 1914 was 79,129,000 lb., against 72,379,000 lb. in 1913 and 65,607,000 lb. in 1912.

The value of the exports of aluminum and of manufactures of aluminum amounted to $1,546,510 in 1914, as compared with $966,094 in 1913.

Aluminum is the most abundant of metals and ranks third among the elements which compose the crust of the earth, being exceeded only by oxygen and silicon.

Tennessee Mines' Output, 1914

The mineral and metal output of Tennessee for 1914 was as follows, the items standing in decreasing order of value: Coal, 5,753,476 tons; pig iron, 2,905,672 tons; copper, 18,249,839 lb.; phosphate rock, 379,826 long tons; zinc, mill ore, 329,943 tons; coke, 234,129 tons; iron ore, 304,675 long tons; limestone, 72,693 tons; silver, 97,302 fine oz.; bauxite, 23,400 long tons; mineral paints, 1600 tons; barytes, 1255 tons; gold, 300 fine oz. There was a considerable production of ceramic and building material which is not covered in the figures given here.

Potash Deposits in India May Be Developed, according to a recent report of the Indian Geological Survey, at Khewra and Nurpur in the Punjab salt range. The Prussian deposits differ markedly from those found in India. They are of course greater in extent, but mineralogically there is also a wide difference. Although both were probably similar at the time of their deposition, the Punjab deposits have been affected to a much greater degree by thermal metamorphism, so that carnallite, for instance, one of the chief products mined at Stassfurt, is unknown in India. Since the outbreak of war the subject has assumed an added importance, for the main sources of the world's supply—the deposits in Germany and Austria—have been cut off. The possibility of the economical exploitation of the Indian deposits has been enhanced, and the subject is now engaging the attention of the government of India.

Details of Practical Mining

Sample Bags and Sample Filing

By Frederick W. Foote*

The accompanying description is of the sample bags I made and used and the method of filing them for reference. The bags are of light-weight canvas. A piece 16x14 in. is split for a couple of inches as in Fig. 1. The flap *A* is then sewed down, leaving a hem sufficiently deep to hold a small stick. The sticks used in the bottom of window shades have been found to be satisfactory. The flap *B* is then sewed down with a piece about 5 in. deep inserted. This piece, *C*, is used as a cover when the bag is finished. The bag then appears as in Fig. 2. It is then folded along the dotted line and sewed together firmly along the line *X*, the bag is turned inside out, and appears as in Fig. 3.

Sticks 12 in. long are then cut and inserted in the hems and fastened with string through holes *D* in the

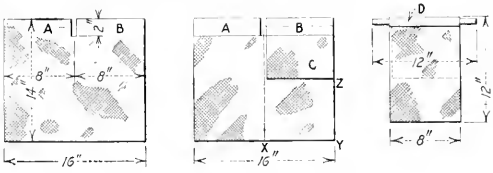

Fig. 1 Fig. 2 Fig. 3

Convenient Sample Sack

sticks. The material for these bags costs 5c. each and one can be made, even by an amateur, in an hour. After the sample has been put in the bag the flap *C* is put outside and rolled under the stick on the opposite side. The ends of the stick are then tied firmly together. The bags when fastened in this manner are good to detect salters. The tops have the appearance of an opening, but the flap underneath will catch any dust that might be inserted. A card stuck in this opening may show the location of the sample and the assay value.

Wishing to keep the samples of several properties separate and easily accessible I devised a rack similar to a filing cabinet, having one tier for each property. These racks were built with 9 in. between the sides, 14 in. in height and were made to slide in and out of the framework. Each sample bag is placed in the rack and held in suspension by the ends of the sticks resting on the framework. In a large property separate racks could be used for each level or any other arrangement most suitable to the individual requirements.

*University, Va.

Compressed-Air Leaks

Too little attention is paid to having compressed-air pipes underground tight and free from leaks. With the advent of the several excellent compressed-air meters now on the market, it is hoped that more attention will be paid to testing compressed-air lines for leaks, and when the amount and cost of these leaks are determined, the present careless inattention to this detail of mining will very quickly be done away with. J. H. Rider, in a paper read before the Institution of Electrical Engineers, states that at a barometer pressure of 24.5 in. an orifice of only ¼-in. diameter will pass 450 lb. of air per hour at 100-lb. pressure. This runs into money very fast, and the common sizzling at joints of air hose around machine drills accounts for a large item of the operating cost.

Cementation Process for Sinking Shafts*

The cementation process is employed where the quantity of water running into the shaft is difficult to keep down with a pump. It is a question also whether, when a shaft is to be sunk in ground that is known to be faulty, and in which water may therefore be expected to rush in through fissures at any moment, it may not be wise to protect the sinking at the commencement by the adoption of the cementation process.

The plan involved in the cementation process is to fill all the fissures through which water can run into the excavations; practically to dam back the water. According to the experience in the United Kingdom, the process is successful, except in certain cases, and it appears that in those cases the freezing process would be even more difficult to carry out.

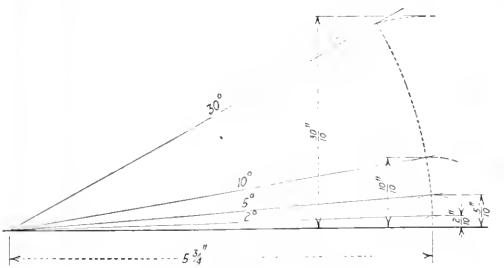
In carrying out the cementation process, a ring of bore holes is put down in the strata through which the shaft is being sunk, and 3-in. pipes are driven into them. In one shaft, which was 25 ft. in diameter, eight bore holes were put down on the inside, the diameter of the ring of bore holes being about 20 ft. The bore holes are first put down to a depth of 9 ft., then 15 ft. of 3-in. casing is forced into each hole, so that the pipe stands above the ground to a height of 6 ft. The diamond drill is then set to work inside of the casing pipes. The diamond drill had a crown 1½ in. in diameter, which gave a core of ⅞ in. The boring is continued until a fissure containing water is met, and it is known when this occurs by the water issuing from the top of the 3-in. pipe. The water is usually under pressure, sometimes being forced up by the pressure of gas, as well as by the pressure of the water in the water-bearing strata. As soon as water appears the boring is discontinued, the drill removed, and a pressure pump connected to the 3-in. pipe. Liquid cement is forced by the pump down the pipe, down the bore hole, and into the fissure under a pressure of from 800 lb. to 1200 lb. per square inch, the idea being to force it into the fissure and to fill it completely. When no more cement can be forced in, the top of the 3-in. pipe is plugged and allowed

*Abstract of paper by Sydney F. Walker, Bloomfield Crescent, Bath, England, in the "Colliery Engineer."

to remain undisturbed for about 30 hours. At the end of that time the plug is removed from the pipe and the cement is drilled down to the fissure; then if no water appears the drilling is continued until another fissure is struck, when the process is repeated. If water appears on drilling out the bore hole, the process is repeated until the fissure is completely closed by cement. The same process is going on at each of the bore holes, and when a depth of 150 to 250 ft. has been reached by this method, rock sinking is commenced and carried to the same depth. After the shaft is sunk and the walling* is put in, the stopping back of the water is further insured by drilling holes at the depths at which fissures were met with, horizontally into the strata behind the walling, and forcing cement in under pressure in the same manner as was done from the surface. Cement is also forced in behind the walling at various points where it is thought desirable or where there is any appearance of water. The horizontal bore holes that are drilled for supplementary cementing are carefully plugged up when everything appears right. After the walling is completed for the 150 ft. or 200 ft. that has then been protected and after the supplementary cementation has been finished, bore holes are drilled down from the bottom of the shaft and the process repeated in the same manner as from the surface. In this way, any reasonable depth of sinking can be carried out.

Laying Out Small Angles

The illustration indicates a simple but accurate method—described by Francis W. Shaw in the *American Machinist* of June 10—of laying out small angles in the absence of a good protractor or drafting machine. The accuracy obtainable this way is said probably to exceed that resulting from the use of a protractor. The error



Laying Out Small Angles

in 1 deg. is but 4 sec.; in 10 deg. it is less than 1 min., and even in 30 deg. but 13 min.

From the base line draw an arc of 5⅜-in. radius and lay out the desired angle along this arc, setting the compasses or dividers to $\frac{1}{10}$ in. for every degree. Join the center of the large arc with the point of intersection of the large and small arcs.

For angles approaching 30 deg., lay out an angle of 30 deg. with the triangle and add or deduct the small angle of difference. For angles near 15 deg., bisect an angle of 30 deg., adding or deducting the difference angle.

*In Great Britain shafts are made of circular cross-section and lined with masonry.

Steel-Tape Repairs

Many engineers and surveyors repair their own steel tapes, the repair outfit consisting of a combined punch and rivet set and copper rivets or eyelets. Few know how to repair a broken tape properly, even when furnished with all the necessary facilities, says *Engineering News*.

The point which needs the most emphasis is that no matter how it is broken, some of the original tape must be cut away and a new piece spliced in. This applies both to graduated ribbon tapes and to most of the heavier flat-wire tapes. Any kind of a mend which stiffens the tape at the splice weakens it and makes it more likely to break

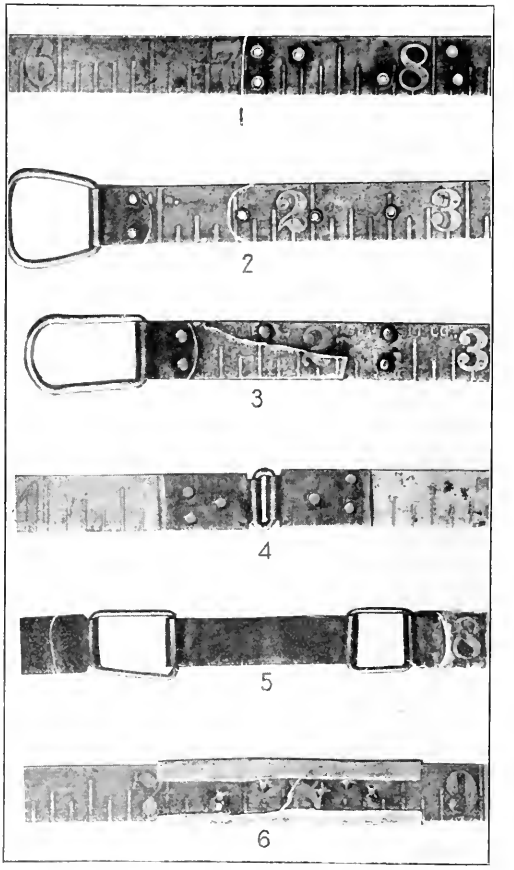


Fig. 1. "Horrible Examples" of Tape Repairs

near there a second time, especially in the case of thin ribbon tapes. The only exception is in the case of heavy wire tapes, ¼-in. wide or less, which are usually so stiff that they can be mended with a soldered sleeve.

In Fig. 1, tapes Nos. 1, 2 and 3 illustrate defective splices. No. 1 is made by lapping the tape by 0.12 ft. and securing the lap with six eyelets. A little consideration would have shown that two eyelets and a 0.02-ft. lap would have done just as well. This is one end of a 0.3-ft. splice, and the tape broke a second time at the left-hand

end of the splice. No. 2 is another lap joint, 0.1 ft. long. In No. 3 the whole of the old tape has been retained and the repair made by riveting a piece 0.15 ft. long on the back; solid rivets are used where eyelets should have been. Nos. 2 and 3 also illustrate defective methods of fastening on the end rings—the laps are too long. The best result is attained if the lap is little more than 0.1 ft.

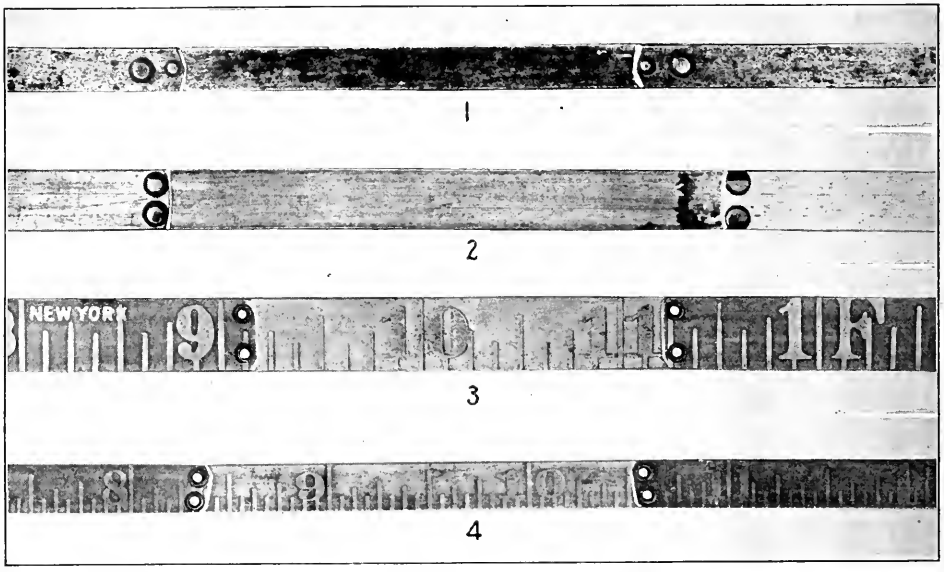

Fig. 2. Examples of Tapes Repaired to Preserve Maximum Flexibility

fastened with two eyelets. Nos. 4 and 5 show conscientious and ingenious attempts to keep flexibility, but by means not to be recommended. No. 6 is a crude but effective repair, no doubt made in camp. The sleeve was probably cut from a tin can, and an axe and nail were used for a punch. There are no rivets and the sleeve holds by depressions punched partly through the tape.

In Fig. 2 is illustrated the proper way to make tape repairs according to directions: First punch two holes in each of the broken ends about 1 in. or more back from the break. Take a piece of tape about 2 in. longer than the completed splice is to be, lay one of the broken ends on the splice, tying it tightly to insure proper alignment, and punch holes in the splice through the holes already

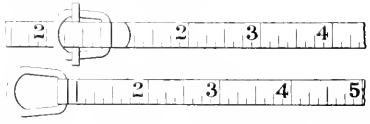

Fig. 3. How to Put the Ring End on a Tape

punched in the tape, placing and setting a rivet as soon as a hole is punched. Solid rivets are used for flat-wire or band tapes, and when the tape is ¼ in. or less wide, the rivets are placed in tandem, as shown in No. 1, Fig. 2. After the splice has been riveted to one end of the broken tape, lay the other broken end on it and butting the two ends of the break together, tie it in place and rivet as before. When all rivets are driven, notch the ends of the tape close to the rivets with an edged file and break the tape on the file marks. In the same manner notch and break off the ends of the splice close to the rivets. The result is a lap of not over 0.03 ft. for a tandem splice and a little over 0.01 ft. (or ⅛ in.) for rivets side by side, which means a tape practically as flexible as new. For thin ribbon tapes eyelets should always be used instead of solid rivets, as shown in Nos. 3 and 4, Fig. 2.

To replace a broken ring or repair a tape broken at the ring, take a piece of similar tape showing any foot mark. Lay the ring with its clip or sleeve in place on this splice-tape, and hold it there by slipping a narrow piece of tape (or a wire) under the splice-tape and over the ring (see Fig. 3). Punch one hole through the ring clip and tape, separate, and cut the tape close to the hole; insert the clip, and rivet, using a long eyelet. Then punch the second hole and rivet as before. Notch the clip with a file close to the eyelets and break it off on both sides of the tape. Rivet the new section to the broken end, not less than 2½ in., or 0.2 ft., from the end, being careful to lay the new piece on top of the old tape.

Don't Blow in a Cap

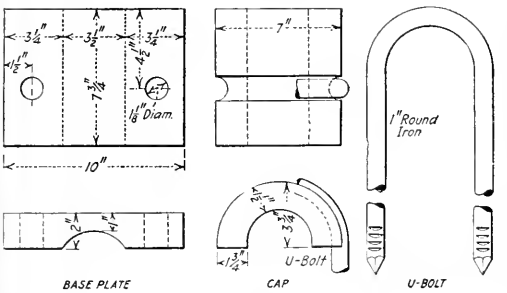
It is very common for miners to blow into fulminate caps when making up primers, in order to blow out any dust, dirt or sawdust which may be therein. This is a very undesirable thing to do, as the moisture from the breath or small globules of saliva may dampen the end of the powder train in the fuse when it is inserted and cause a cut-off or even a misfire. Neither should the cap be rapped on anything hard to loosen and shake out any dirt. If the caps are properly taken care of they will not get full of dirt.

Details of Milling and Smelting

Sectional Stamp-Stem Guide

The sectional cast-iron stamp-stem guide, designed and recently installed at one of the larger Nevada stamp mills, is shown in the accompanying drawing. Before this guide was adopted, a nonsectional, two-bolt, cast-iron guide was in use, but as a great many of these were either broken or badly worn, it was decided to gradually equip the mill with new guides.

A few sets of the cylindrical shell-type guides were tried, and while on the whole satisfactory, great difficulty was experienced at times in removing a shell from the frame. The guide shown was finally decided upon and has proved excellent in every particular. Its initial cost is moderate; it may easily be attached to any wooden battery-frame; it is unbreakable, adjustable and very easily manipulated when turning or putting in a stem. It will be noticed that the ends of the U-bolt are well tapered. It is necessary, at times, to drive the U-bolt through the guide timbers with a few light blows of a hammer, and



DETAILS OF SECTIONAL GUIDE

having the bolt-ends tapered prevents any stripping of the threads. The guides weigh 73 lb. per set and cost, laid down at the plant, $8.43 per pair (one stem), the freight charge being $1.50 per pair.

Moving Water-Tube Boilers

At Garfield, Utah, two 350-hp. Stirling water-tube boilers were recently moved from the boiler house to the reverberatory building, a distance of about 1000 ft., without having the tubes dismantled. The boilers were formerly used as direct-fired boilers, but will hereafter be employed as waste-heat boilers. The engineer in charge was agreeably surprised to find, when the boilers were moved and tested with a water pressure of over 100 lb., that they did not show any signs of leakage. It was expected that many of the tubes might have to be rerolled. The boilers were placed on a car, and after they were once in this position, they might be moved several hundred miles as easily as the shorter distance, provided the overall dimensions were not too great for railroad clearances.

Van Arsdale's Method of Copper-Ore Treatment

A new method of treating copper ores is proposed by George D. Van Arsdale, of East Orange, N. J., for which he has been granted U. S. pats. 1,119,477 and 1,119,478. This is a leaching process, the solution having a base of sulphuric acid containing copper.

Heretofore sulphur dioxide has been added to such leaching solutions before electrolyzing for the purpose of reducing polarization, and similar methods using chloride solutions have been proposed. None of these has been commercially successful, since in the conditions present while employing them, a part or all of the copper is precipitated as sulphide compounds and not as metallic copper. This disadvantageous feature is caused by the electrolytic hydrogen evolved at the cathode reacting with the sulphur dioxide present and forming hydrogen sulphide, which then precipitates copper as sulphide. This side reaction is undesirable, since copper sulphide is not marketable as such and requires further treatment before it can be sold. Van Arsdale claims to have discovered that such deposition of copper-sulphide compounds can be prevented.

He prefers to use a solution of copper sulphate, which may be made by dissolving copper sulphate in water or by making a solution of copper sulphate from copper ores which have been roasted. Such solutions contain ferrous sulphate, which, in former practice, has been undesirable, but which, according to the new method, is made a desirable factor. The next step is to add, in any of the well-known ways, sulphur dioxide, and the resulting solution is treated electrolytically. A function of the sulphur dioxide is not only to act as a depolarizer, but also to reduce any ferric sulphate present in the solution to the ferrous state, which also tends to prevent polarization at the anodes, the ferrous sulphate combining with nascent oxygen at the anode to form ferric sulphate. He prefers to work without a separating diaphragm and to regulate the voltage and speed of deposition so that copper only is separated, and not hydrogen or hydrogen sulphide. With a 10% solution of copper sulphate containing sulphur dioxide sufficient to prevent polarization and to reduce all salts of iron to the ferrous state, it is found that with about 10 amp. per sq.ft. and between 0.7 and 1.2 volts, it is possible to precipitate about 80% of the copper before the formation of sulphide commences. Precipitation is stopped at that point, and the solution will then contain free sulphuric acid and copper sulphate. This solution is used again for further ore treatment, approximately the original solution being regenerated each time. The voltage and amperage as above given are not fixed for all cases, but represent only a particular case, and may be varied at will to suit the different ores which are being worked upon.

The second patent of the numbers mentioned relates to a process for changing the copper in ores into soluble

copper compounds, dissolving them and then precipitating the copper from the resultant solutions, and its object is to provide a simple and inexpensive method for accomplishing these purposes. After being ground, the ore is roasted with a suitable material to form copper compounds which are soluble in water. If copper sulphates are desired, the ore may be roasted with pyrite (if there is not enough sulphur present) or with salt, a soluble chloride product being obtained. Then excess of sulphur does no particular harm. During the roasting, particular attention should be paid to the temperature and other factors to obtain the maximum amount of copper compounds which are soluble in water. After roasting, these compounds may be leached out with water, which may be acidulated by the addition of a desired amount of liquid from a preceding operation to dissolve the copper present in the form of sulphates and oxides.

In beginning the leaching operation, it will be necessary to use dilute sulphuric acid to acidulate the wash water, but after the first step the acid will be generated through the process. The solution is withdrawn from the ore as completely as possible, water or weak solution added to the residue, agitation and leaching repeated, and the wash liquid withdrawn. A part or all of this first wash water is added to the first solution to maintain a desired standard strength and volume of solution for succeeding steps of the process. The ore which contains the copper separated by these operations is again subjected to washing with water or weak solution, and the resulting second-wash liquid passed over iron to recover such copper as may be in it and then, with its impurities, allowed to run to waste. By properly choosing the amount of solution rejected in this way, the main solutions in the cycle of operations may be kept as free from accumulated impurities as necessary. The first liquor from the ore, with the wash solutions added to it, is now subjected to electrolysis in the presence of sulphur dioxide. The amount of sulphur dioxide added may be sufficient to satisfy the equation

$$CuSO_4 + SO_2 = Cu + 2\,H_2SO_4$$

but in many cases it is sufficient to supply only enough sulphur dioxide to keep the iron salts, which are always present, reduced to the ferrous state.

In ordinary electrolysis, with an insoluble anode, a high voltage is required, but by operating in this manner the voltage may be greatly reduced and the amount of copper precipitated per unit of power is such as to render this method essentially economical.

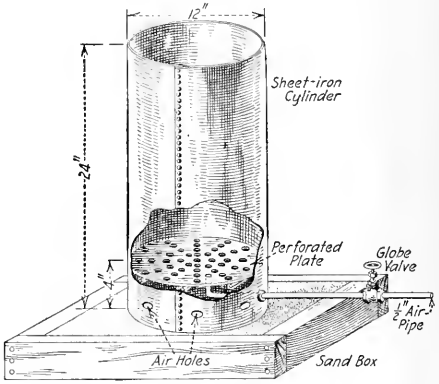
Recovering Zinc from Leaching Solutions

A process for the recovery of zinc from the waste solutions obtained in copper leaching has been patented by Wilhelm Buddeus, of Charlottenburg, Germany (U. S. pat. 1,120,683). These solutions contain a considerable amount of iron in addition to the zinc, and Dr. Buddeus states that the present method of oxidizing the iron to the ferric state and then precipitating it before recovering the zinc is not commercially feasible because of the high price of the various oxidizing agents. Accordingly, he suggests precipitating the zinc and ferrous iron by means of burnt lime, magnesia or ground limestone, filtering the slimy mass thus obtained and then drying so as to oxidize the ferrous iron completely to the ferric state. The dried mass is then treated with sufficient acid to remove the zinc; the iron will then be left undissolved.

If lime be used for the complete precipitation of the zinc and ferrous iron, the precipitate will carry down a considerable amount of calcium sulphate. However, he states that from the resulting product the zinc can be removed if the acid corresponds exactly to the amount of zinc contained in the product under treatment. In this case he says the calcium sulphate will remain behind along with the ferric oxide.

Coke Heater for Milling Plants

Small mills are sometimes built without heating facilities, or with the intention of heating by stoves, while sometimes in larger plants where heating systems have been installed, the installations have been found to be inadequate and some auxiliary form must be resorted to. A heater which will take the place of a stove either as the main source of heat in a small mill or as an auxiliary in



Stove for Heating Small Mill

a larger plant, and which is simple and inexpensive to make and operate, is shown in the accompanying illustration.

It consists of a sheet-iron cylinder 2 ft. high by 1 ft. in diameter, open at the top and bottom. About 4 in. from the bottom three or four pieces of ¼- or ⅜-in. round iron are run through the cylinder, and upon these is placed an iron plate perforated with a number of ½-in. holes. Just under the plate six or eight 1-in. holes are cut in the cylinder to admit air. Compressed air is conducted in through a ½-in. pipe fitted with a globe valve, the end of the air pipe being bent up under one of the holes in the plate. In operating, a little oily waste, some wood and a mild blast will ignite the coke. The temperature is regulated by the blast and considerable heat is developed with small fuel consumption. In cleaning, the heater is first allowed to cool. It is then shipped away from the air pipe and the contents dumped, the coke then being easily sorted from the ash. This heater, if placed upon a sand box, may be operated upon a wood floor with perfect safety, as almost no heat goes down. A perforated plate over the top of the cylinder will make the heater as serviceable as a stove in warming oil cans, lunch buckets and the other uses customary in such cases.

Company Reports

Alaska Gold Mines Co. in 1914

The 1914 report of the Alaska Gold Mines Co., Juneau, Alaska, shows that the company owned $3,268,000 par value of Alaska-Gastineau Mining Co. bonds out of a total issue of $3,500,000 and $11,438,670 par value of its stock out of a total issue of $12,000,000. During the year a policy of construction and equipment was carried out with the view of ultimately treating 20,000 tons per day. Owing to this policy the company borrowed $750,000 during the year and has provided for a bond issue of $1,500,000. The mine is fully developed for an output of 6000 tons a day, the capacity originally planned.

There were 28,523 ft. of drifts, raises and crosscuts driven during the year and 6203 ft. of diamond drilling was done. This includes the completion of the Sheep Creek tunnel, which is nearly two miles in length. Development work to date by the present company totals 63,248 ft., including 7545 ft. of diamond drilling. It is stated that very little work was done during 1914 to prove directly additional ore because the tonnage already developed is sufficiently great. The work was directed almost wholly to blocking out more thoroughly ore from which active production would first begin. This makes it possible to give some statement of the tonnage blocked out. A block of ore lying west of No. 2 incline shaft and above level No. 10 is estimated to contain 21,000,000 tons of fully developed ore averaging slightly less than $2 per ton. From all data at hand, and considering the known continuous and uniform nature of these ore deposits, a minimum estimate of fully developed, partly developed and probable ore could not, the report says, reasonably be stated at less than from 75,000,000 to 100,000,000 tons having a recoverable value of $1.50 per ton. These figures contemplate no consideration of orebodies extending below sea level.

To increase the tonnage capacity beyond 6000 tons a day some further equipment in compressor plant, mine-haulage system and living accommodations for employees will be necessary. An additional electric locomotive and a few additional cars will be required for the Sheep Creek railroad from the new mill to the bottom of the main shaft. Some additions to power plants will also be necessary.

At the Salmon Creek power plant the dam is 165 ft. high and has had a maximum of 135 ft. of water behind it, without showing any signs of material leakage or any undue deflection. With the completion of a small amount of unfinished construction this project will be developed to a point where the cost of power will probably not exceed $1000 per month for 6000 hp. Another source of power has been selected that may finally develop a year-round capacity of 11,000 hp. This may be developed gradually, beginning with about 4000 hp. and working up to maximum capacity.

At the time of writing the report one section of the mill had been in continuous operation for practically one month and was being worked up to a capacity of about 2000 tons a day, which would give a capacity of 8000 tons a day for the entire plant. It is believed that when everything is working smoothly the plant will have a capacity of 10,000 tons a day, and with some additions to the crushing plant it can be made to treat 12,000 tons. From the treatment of about 40,000 tons, recoveries have been in excess of $1.50 per ton from ore containing $1.85 per ton in gold and silver. Tailings are expected to average from 20 to 25c. per ton on ore containing approximately $2 when operations have become systematized. The main mill produces nothing but concentrates, at the ratio of about 1 ton of concentrates for each 50 or 60 tons of ore. In the retreatment plant the coarse gold containing some silver is separated from these concentrates and reduced to bullion. This separation is also accompanied by the production of a small tonnage of lead concentrates containing gold and silver, the concentrate for the present being shipped to smelters on the Pacific Coast. The residual portions of the original concentrates consisting principally of iron and zinc sulphides, are ground and amalgamated and the resultant iron-zinc tailings discarded. The report contains a map and several photographs of the property.

Anaconda in 1914

The Anaconda Copper Co., Butte, Mont., in its report for 1914 shows a total production of 223,720,292 lb. of refined copper, 8,314,115 oz. of silver and 99,650 oz. of gold, of which 205,298,531 lb. of fine copper, 7,221,815 oz. of silver and 99,650 oz. of gold came from ores produced from the company's mines. The profit and loss statement given in the report shows a profit of $8,789,587; dividend payments amounting to $9,077,500 were made. The mines of the company produced 3,898,100 tons of ore and 6782 tons of precipitates. The reduction works at Anaconda treated 3,748,726 tons of ore and other cupriferous material and 488,243 tons were treated at the Great Falls plant. Of this aggregate 3,768,640 tons came from the company's mines, 457,903 were from outside mines and 426 tons of precipitates came from cleanings and old works. Some of the expenses as charged in the profit and loss statement follow: Mining expense, including development, $15,298,517; ore purchases, including transportation, $1,695,809; transportation of ore from mines to reduction works, $1,023,171; reduction expense at Anaconda and Great Falls, $6,862,306; transportation of metals from West to East, refining and selling charges, $2,998,097; administration expense and Federal corporation tax, $272,411; depreciation of plants, etc., written off, $845,628; and interest, $408,831. Of the profit reported before allowing for depreciation and interest charges, $7,200,556 came directly from operations and $2,843,491 from investments and subsidiary companies.

During 1914, 330,000 shares of Anaconda stock were exchanged for the 100,000 shares outstanding of the International Smelting & Refining Co., and this company was dissolved and the International Smelting Co. was in-

corporated for $15,000,000, consisting of 150,000 shares of $100 each, of which 95,000 shares were issued, all of which were delivered to the Anaconda company in payment for the properties turned over by the Anaconda. It is estimated that improvements contemplated in the reduction works department will cost about $6,000,000.

In the Anaconda mines 33.15 miles of development work was performed, and it is estimated that a tonnage of ore slightly in excess of the amount extracted was added to the ore reserves. The coal department produced 619,208 tons of coal, of which 420,362 tons were shipped to other departments of the company, 140,830 tons were sold commercially and 58,016 tons were used at the coal mines.

The lumber department cut 84,411,461 ft. of lumber, and purchased 23,373,493 ft. It shipped 50,701,581 ft. to the mines of the company, sold 46,118,118 ft. commercially, used 60,083 ft. at the mills for repairs and construction and supplied 3,284,217 ft. to the factory.

The railroad transported 5,380,045 tons of ore and freight and 306,065 passengers. The net income from this business amounted to $267,822, including rentals for tracks, etc. A dividend of ½% was paid by this department.

Tonopah Mining Co.

The report of the Tonopah Mining Co., Tonopah, Nev., for year ending Feb. 28, 1915, shows a total production of 143,602 tons of ore, consisting of 113,616 tons of mine ore and 29,986 tons of dump ore. This ore was treated in the mill and averaged by assay 0.246 oz. of gold and 21.22 oz. of silver per ton. Total net earnings and income for the year were $1,050,124, of which $225,803 represents dividends from investments, etc. Dividends aggregated $1,000,000. A statement of receipts and disbursements shows that there was an excess of disbursements over receipts of $205,733, including dividend payments. A statement of costs shows that the average gross value of the ore milled was $16.25 per ton, of which $1.23 was lost in milling and refining, $8.51 paid out in costs and $6.51 represented by profits. The details of costs per ton were: Mining and handling dump ore, $4.40; milling, $2.96; freight on ore milled, 74c.; and marketing products, 41c. The total dividend record shows that $12,600,000 has been paid to date, not including $380,557 paid out in retiring an issue of preferred stock.

The company owns 83.33% of the stock of the Tonopah Placers Co., Breckenridge, Colo., and has also purchased a property in Nicaragua and contemplates the erection of a 100-ton mill on this property.

New York & Honduras Rosario

The New York & Honduras Rosario Mining Co., San Juancito, Honduras, reports for 1914 a production of 109,170 tons of ore containing by mine assay 1,834,361 oz. of silver and 14,298 oz. of gold. The extraction was 88.662%. The income from the production of gold and silver amounted to $1,239,877. After deducting expenditures and crediting miscellaneous earnings there was a profit of $329,814, of which $240,000 was paid out in dividends. The total bullion production of this company from 1882 to 1914 inclusive amounts to $19,981,206, and dividends amounting to $3,550,000 have been paid from this production. The costs as reported for operating were: Mining, 9.96 pesos; milling, 5.05 pesos; administration, 2.28 pesos; total, 17.29 pesos. In 1914 the average value of a peso was 41c. Ore reserves are estimated to contain 418,978 tons of ore, averaging $10.45 per ton. The mill has treated 299 tons per day, which is nearly 50% more than its original rated capacity. The actual consumption of power for crushing was 8 hp.; stamping, 92.4 hp.; grinding, 242.1 hp. These figures show a consumption of 1.7 hp. per ton of ore treated. The two power plants produced an average of 947.6 hp. per day at a cost of $19.90 per hp. per year, or $0.227 per hp.-hr.

Copper Range in 1914

The Copper Range Consolidated Co., Painesdale, Mich., for 1914, shows a net income of $494,600 from 27,857,457 lb. of copper produced by its subsidiaries. This copper was sold for 13.38c. a lb., making receipts from product $3,726,389. The operating expenses were $2,855,340, leaving a mining profit of $871,049. Receipts from the Copper Range railroad amounted to $25,274, and $10,673 was received from the Atlantic mine, making the total income $906,996. Other expenses amounted to $83,308; and $329,088 was paid to St. Mary's Mineral Land Co. for its share of the profits of the Champion mine, leaving a net income as stated. No dividends were paid in 1914, but dividends to date aggregate $13,986,746. The following comparison of 1914 operations is made, including only one-half the output and profits of the Champion:

	1914	1905 to 1914, Inclusive—Average
Tons of rock stamped	909,110	1,349,739
Refined copper produced, lb.	19,953,854	29,284,999
Refined copper per ton ore, lb.	21.95	21.70
Total cost per lb. copper	10.66c.	9.97c.
Price received per lb. copper	13.38c.	14.85c.
Profit per lb. copper	2.72c.	4.48c.
Net earnings, Copper Range Cons.	$494,600	$1,648,170

The Baltic mine produced 7,001,945 lb. of copper and made a profit of $154,233, making a total surplus of $490,550 on hand at the end of the year. The total production of the Baltic to date is 176,129,415 lb. of copper. No dividends were paid in 1914, but dividends to date amount to $7,950,000. The following table gives a comparison of 1914 operations with the average for the last 10 years:

	1914	1905 to 1914, Inclusive—Average
Tons of rock stamped	324,433	638,267
Refined copper produced, lb.	7,001,945	14,206,204
Refined copper per ton ore, lb.	21.58	22.25
Total cost per lb. copper	11.17c.	9.29c.
Price received per lb. copper	13.38c.	14.76c.
Profit per lb. copper	2.21c.	5.47c.
Net earnings	$154,233	$776,488

The Champion Copper Co. produced 15,807,206 lb. of copper and made a profit of $658,175, which was added to surplus, making $1,206,819 at the end of the year. Dividends to date aggregate $8,400,000 from a production of 191,864,475 lb. of copper. The following table compares the operations of 1914 with the average for the last 10 years:

	1914	1905 to 1914, Inclusive—Average
Tons of rock stamped	614,854	679,202
Refined copper produced, lb.	15,807,206	16,492,059
Refined copper per ton ore, lb.	25.71	24.28
Total cost per lb. copper	9.21c.	9.34c.
Price received per lb. copper	13.38c.	14.77c.
Profit per lb. copper	4.17c.	5.43c.
Net earnings	$658,175	$894,306

The Trimountain Copper Co. produced 5,048,306 lb. of copper at a profit of $58,639, which was added to surplus. There was a surplus balance of $503,397 on hand

at the end of the year, and dividends to date aggregate $1,450,000. Copper production to date amounts to 93,506,574 lb. The following table gives a comparison of 1914 operations with former years:

	1914	1905 to 1914, Inclusive—Average
Tons of rock stamped	227,251	371,871
Refined copper produced, lb.	5,048,306	6,832,766
Refined copper per ton of ore, lb.	18.21	18.37
Total cost per lb. copper	12.21c.	12.15c.
Price received per lb. copper	13.38c.	15.16c.
Profit per lb. copper	1.17c.	3.01c.
Net earnings	$58,639	$205,861

Inspiration in 1914

The Inspiration Copper Co., Miami, Ariz., in its report for 1914 summarizes its stock issue as follows:

	Shares
Total shares issued and outstanding, including 39,797 shares issued for New Keystone property	762,755
Reserved for redemption of first mortgage bonds	240,000
Reserved for redemption of debenture bonds	180,000
Total authorized, including stock reserved for conversion of bonds	$1,182,755
Balance unissued	317,245
Total capital stock	$1,500,000

During the year the New Keystone property was purchased by the Inspiration for $795,940, payable in 39,797 shares of the company's stock. The property holdings of the company now total 3528 acres, of which 1881 acres are mining lands, 615 acres mill site and tailing lands, and 1032 acres ranches, water lands, etc.

It is stated that copper production would begin during June, 1915, and the mill when in full operation will have a daily capacity of from 14,000 to 15,000 tons. The scheme of treatment in general terms follows: At the mine the ore will be subject to two crushing operations—first to 4-in. maximum size in gyratory crushers, next to 1.5-in. maximum size by Symons disk crushers. In the mill the product will be ground in Marcy ball mills to pass a 48-mesh screen, then treated in flotation machines, followed by a separation of flotation tailings into sands and slimes. The sands will be treated on concentrating tables, and the slimes will be retreated in flotation machines. The concentrates will be dewatered in a filter plant. The ore from the mine will be delivered to one set of double concrete bins underground holding 3700 tons and hoisted through twin concrete-lined shafts to a bin of 2000 tons capacity located between the shafts. The total hoisting depth will be 630 ft., and the hoisting and coarse-crushing equipment will have a capacity of 1000 tons per hr. The ore crushed at the mine will be stored in a 25,000-ton bin. From this bin it will be hauled 1.6 miles in 60-ton railroad cars to the mill storage bin of 12,000 tons capacity. During the year 102,066 ft. of development work was done, consisting of 6114 ft. of large haulageways, 31,048 ft. of ordinary-sized drifts and 64,904 ft. of raises. Development work to the end of the year totals 42.9 miles and includes 1.2 miles of shafts, 7.4 miles of large haulageways, 18 miles of ordinary-sized drifts and 16.3 miles of raises. There has also been 29.33 miles of holes churn drilled on the property.

The ore will be undercut and caved in blocks of probably 70 ft. vertical dimensions and delivered to haulage drifts below through vertical raises. Ore reserves are estimated to contain 97,143,000 tons of 1.63% ore. This consists of 46,252,000 tons of 2.01% sulphide ore, 28,698,000 tons of 1.26% ore, 17,460,300 tons of 1.31% oxidized material and 4,732,700 tons of 1.31% mixed carbonate and sulphide material. Tests have demonstrated that the milling process will save from 86.7 to 90.3% of the copper in the sulphide ores and from 20 to 30% of the copper in the oxidized ores. During 1914, 172,722 tons averaging 1.52% copper were treated. The average quantity of copper oxide in the ore milled was 0.16% of the total. It is estimated that the concentrates will average from 28 to 32% copper.

Mason Valley in 1914

The Mason Valley Mines Co., Thompson, Nev., reports a deficit of $40,274 for 1914. The smeltery treated 75,038 tons of company ore and 67,159 tons of custom ore, or a total of 142,197 tons. The metal production consisted of 9,127,974 lb. of copper, 11,553 oz. of gold and 221,151 oz. of silver. Development work consisted of 419 ft. of drifts, 385 ft. of crosscuts and 1191 ft. of raises. It is stated that future smelting operations are dependent upon the stability of the copper market, the available tonnage of custom ore and the development of the Mason Valley property. The report also states that a prominent geologist was employed for the purpose of making a special study and investigation of the geological conditions and to recommend the most consistent line for further prospecting on the property.

Iron Silver

The Iron Silver Mining Co., Leadville, Colo., for 1914 reports a total income of $421,661; gross expenses, $247,032, and a net operating realization of $174,629. Dividends amounting to $100,000 were paid. The surplus at the end of the year was $428,167. The following table shows details of ore production from the various properties:

	Moyer Mine	Tucson Mine	Blind Tom Mine	Leases
Tons of ore	23,651	13,932	395	14,512
Value of ore	$236,789	$159,710	$1,549	$61,519
Metal contents:				
Gold, oz.	736.49	68.86	.....	117.75
Silver, oz.	207,344	66,271	2,334	52,027
Lead, lb.	6,830,904	2,509,519	.....	1,268,311
Zinc, lb.	5,937,154	7,625,255	36,925	3,797,028
Iron, lb.	3,849,409	126,053	208,835	1,063,118
Copper, lb.	.....	12,751	.....	.....

Algomah Mining Co., Houghton, Mich., reports for 1914 that no mining work was done. A selected ore shipment was made from shaft-sinking operations amounting to 12,467 lb. of copper, for which it received $1695. Total expenses were $17,119, and assets amounted to $14,597 at Dec. 31.

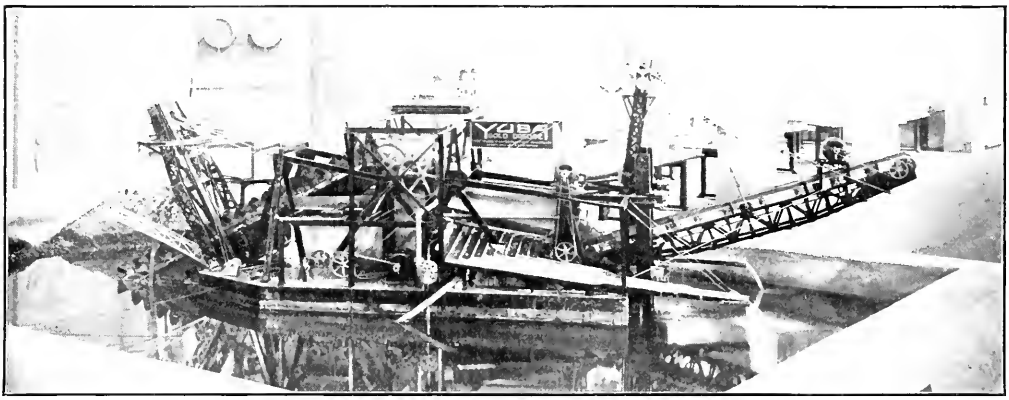
North Lake Mining Co., Houghton, Mich., for 1914 reports a balance of assets amounting to $18,946, after payment of $30,749 for expenses. Work was resumed in May, and 788 ft. of crosscutting was done at a cost of $16.18 per ft. In addition to work now going on it is recommended that the shaft be sunk to 800 ft. and a crosscut run to the east to cut the lodes indicated by diamond drilling.

The La Salle Copper Co., Houghton, Mich., for 1914 reports that 45,509 tons of rock was treated, which produced 540,731 lb. of refined copper, or an average of 11.88 lb. per ton of rock. The expenses amounted to $48,668 more than the receipts from the sale of the product. The balance of the assets at the end of the year was $110,158. A total of 1123 ft. of development work and 94 ft. of shaft sinking was done.

Indiana Mining Co., Houghton, Mich., for 1914 reports that 1152 ft. of crosscutting was done at a cost of $11.13 per ft. Total mine expenses were $28,542, other expenses in Boston made the total expenses $26,286. Accounts show a deficit of $29,523 at the end of the year. Work at present is confined to finding No. 2 drill hole at the 600-ft. level with the object of surveying from this point positively to locate the rich felsite found by the drill at 1450 ft. depth.

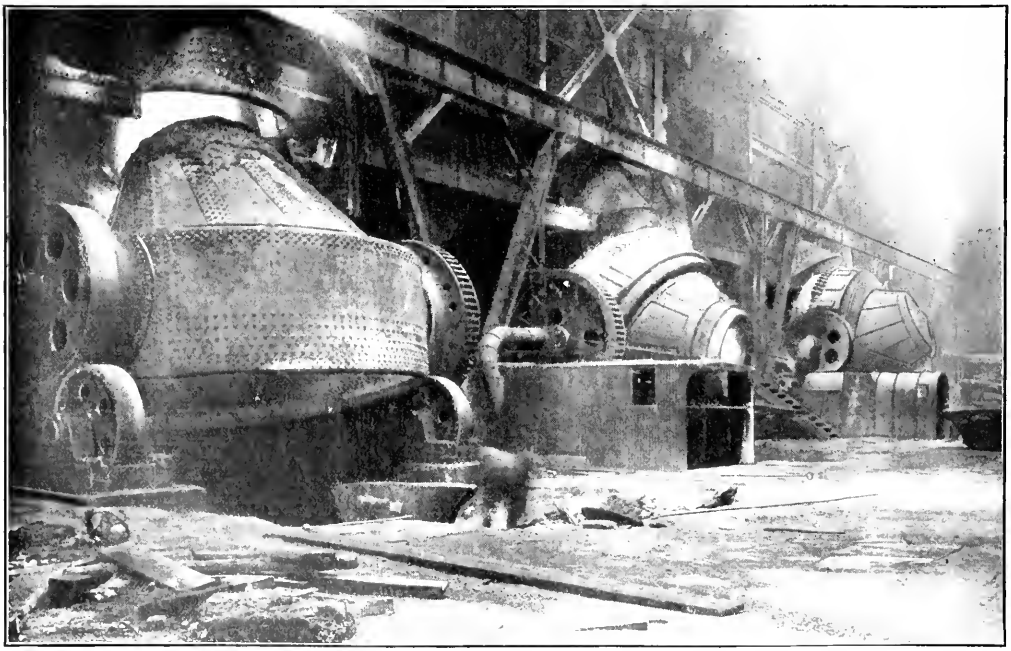
The Pittsmont Copper Co., Butte, Mont., for 1914 reports that its bonded indebtedness to the East Butte Copper Mining Co. was reduced $77,231 and that $80,590 was paid on bond interest through rentals received from the East Butte. The obligations of the company were: Bonds, $1,286,258; accounts payable, $75,997, and cumulative dividends on preferred stock at 6%, $420,000. At the close of the year the company had $1206 in cash and $7100 in accounts receivable.

Photographs from the Field



MODEL OF YUBA NO. 14 DREDGE

A reproduction in miniature of a 16-cu.ft. bucket dredge, the original of which is one of the largest and most modern of gold dredges. It is operated by the Yuba Consolidated Gold Fields, at Hammonton, Calif., on the American River. The hull and machinery of the model are made to a scale of 1 to 20, and the buckets 1 in. to the foot. The model is complete in every detail, except that for display purposes the housing has been left off and only one set of gold-saving tables installed. One of these models is in the Palace of Mines at the Panama-Pacific International Exposition and another in the California State Building



THE GREAT FALLS CONVERTERS AT ANACONDA

The big vertical converters developed by the Great Falls metallurgists have now been adopted as standard for the Washoe Reduction Works at Anaconda. This is in line with the unified metallurgical policy indicated in the appointment of a metallurgical engineer for the two plants. The converters are approximately 20 ft. in diameter and are basic lined. Seven have been installed to replace the horizontal-type converters previously used

Correspondence and Discussion

The Unemployed Engineer

I have read with a good deal of interest the articles that have appeared in the JOURNAL of late with reference to the "Unemployed Engineer."

There is a phase of unemployment or rather scarcity of business affecting the independent practicing engineer which, while it may not be so apparent to the man with his office on Broadway or the prominent consulting engineer, works quite a hardship on the man of the West. I refer to the practice of the faculty of our engineering universities bidding for and engaging in custom work. I am presenting a condition as it appears in the West and as such it is worthy of consideration.

When a technical graduate elects teaching as his specialty, his efforts should be restricted to that field. If his position gives him time to engage in custom work; if his salary as an instructor enables him to do the work more cheaply; if his connection with the institution gives him a large amount of free advertising, then he is possessed of an advantage over the other man which is neither derived through merit nor built up by long practice. The competition is obviously unfair and results show it.

At one of our Western universities last winter the department of metallurgy was headed by a Columbia graduate of the previous year and a stranger to that community. Yet, while the long-established firms doing a general work in assaying and chemistry were having nothing to do to speak of, the laboratories of this university were constantly employed in custom assaying, coal and chemical analysis and metallurgical work in general. The professors were off on private work in periods ranging from two weeks to three months. They were always engaged on reports, maps and other outside work.

When a condition like that prevails it is almost hopeless for the independent engineer to try for any work. We are deeply indebted to our faculty members for a great deal of research work that has been done. Let them confine themselves to such research work and if they desire to do custom work let them do it free of charge. How long would they then continue?

I heard one professor in a public address make the statement that "the reason people come to us to have their work done is because they know they will get a square deal; that an honest effort will be made to perform the service asked; that a correct report will be made of same; and that they will not get stuck for a fat fee whether any service is rendered or not." This sentiment is not only ridiculous but is also a reflection on the whole engineering profession.

It is unfair for a faculty to instruct a number of students in preparation for a profession and then turn around and try to keep them out of that profession after they are graduated. This competition is doing that very thing every day.

I believe this matter could be very aptly handled by the JOURNAL by the creation of a higher standard of professional ethics between the practicing and collegiate engineers.

S. A. CRANDALL.

Tacoma, Wash., June 23, 1915.

Recent Progress in Flotation

In the JOURNAL of June 19, 1915, A. Schwarz discusses our article on "Recent Progress in Flotation," published in the JOURNAL of May 29, 1915.

He states he believes the basic patent on the process of sulphatizing of oxide and carbonate ores belongs to him, and that it was taken out in 1905. He also says he has been at work on the idea ever since. Such being the case, he has doubtless accumulated a great fund of information on the subject which the metallurgical profession would welcome at the present time, for, so far as we know, there has been very little published on the actual results obtained when using this kind of flotation. Our own work extends over a period of one year, during which time Mr. Cameron has given undivided attention to the subject and has been assisted by two other men at different times, Mr. Ralston having general direction of the work. For this reason we feel that we can assure Mr. Schwarz that our conclusions have not been hasty, and that we really have accumulated a great deal of data which we expect to publish in due time.

Meanwhile, replying to the inquiry raised in Mr. Schwarz's letter as to the conditions under which our tests were run, on which we based our statement that only a low-grade concentrate of lead was obtained, the ores tested were of "low-grade" (as stated in our paper), and to make this more definite, we may add that they contained 3 to 5% of lead, and 3 to 10 oz. of silver, associated with the carbonate of lead. The treatment of such ores gave us a concentrate of about 20% Pb, which we think is unsatisfactory. On the other hand, we agree with Mr. Schwarz that a 20% copper concentrate is thoroughly satisfactory. We are particularly glad that our statement has brought out the fact that Mr. Schwarz has obtained concentrates of lead carbonate running as high as 53% and 71.50% Pb. We believe that with heads running over 10% in lead, as carbonate, that it would be possible to get concentrates of a grade approximating that obtained by Mr. Schwarz, as this is a general principal of ore dressing, namely, the higher grade the heads, the easier it is to get high-grade concentrates and high extractions. Mr. Schwarz does not state what the conditions were under which his tests were run, but we venture to predict that they were on ore of a higher grade than was ours. We have retreated our 20% lead froth and got as high as a 36% product, which still leaves much to be desired. We intend to continue our work until more favorable results can be obtained, unless Mr. Schwarz can see his way clear to publish his own

results and thus save our duplicating his work. We appreciate what he has already told us and hope that we may hear from him further on this subject.

OLIVER C. RALSTON,
FRANK CAMERON.

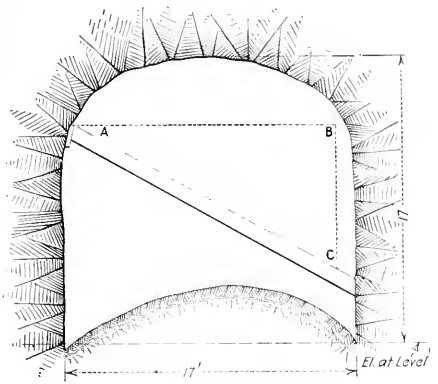
Salt Lake City, Utah, June 24, 1915.

Timbering Stopes for Safety

I hope the following will answer the inquiry of "Sourdough" in the JOURNAL of June 5:

The method used to determine the angle between the timbers of a truss and the consequent miter bevel in "Timbering Stopes for Safety"[1] is herewith explained. For example, let the figure represent a stope to be timbered where the main timber is to be a stull, the position and inclination of which are determined by means of a tape or slide staff and also by the shape of the ground at *A* for heading.

The hitch is then cut and the stull placed firmly in position with a head board at the upper end. A tape is now stretched to indicate the positions which the two other timbers of the truss will assume later, as shown by the dotted line *A, B, C*, in the figure, the tape representing the outside edge of these two members. The tape is read at *B* and at *C* to determine the lengths of numbers



SAFETY TIMBER IN STOPE

AB and *BC*, and the angles at *A*, *B* and *C*, which will be the angles formed by the timbers *AB*, *BC* and *AC* after the truss is framed, are measured.

The timbers of the truss are cut at a bevel equal to half the angle which they will form later when in position. The angles are determined by means of the tape as shown by the dotted line in the sketch; the position of the tape depends upon the shape of the ground. The angles made by the tape in its position are measured by means of a carpenter's miter, the legs of which, for instance, in measuring the angle *ABC* are made to coincide with the two portions of the tape *AB* and *BC* respectively, the apex of the miter being coincident with the point *B* on the tape.

The determination of the proper miter bevel is readily done. If the carpenter's miter used is a degree miter, the angle *ABC* can be read in degrees and the miter set for one-half angle *ABC*, which gives the miter bevel desired. If the miter is not a degree miter, the distance between the two legs is measured with a rule and the miter then reset to half the distance measured on the rule, which gives an angle of one-half *ABC* as before, since the two legs of the miter are of the same length and form the sides of an isosceles triangle where the median bisects the angle included between the legs of the miter, the rule forming the third side of the triangle.

As the tape was stretched so as to represent the outside edge of the truss members *AB* and *BC* and the lengths noted, these distances can be laid off on a fairly straight stick of timber and the bevels cut at the proper point by placing the carpenter's miter on the timber, so that one leg coincides with the edge of the timber, the other giving the desired bevel at which the timber is to be cut.

The material used for timbering the back of a stope for safety is practically all recovered and the short blocking as well. After all the ore has been removed from the stope through the chutes in the set timbers below and these set timbers removed to be used again in another stope, the stope is filled with rock or waste up to the next level and graded to 1% in favor of the load. The back of the stope before it was timbered was mined to a height of from 15 to 18 ft. above the elevation of the level or floor at which the stope will proceed upward again. This affords ample space to stand the set timbers again, upon which to mine and carry the stope up another lift, and it also permits good working room for the miners to drill. Furthermore, it enables the timbermen to recover the timber easily from the back of the stope without staging.

The set timber used consists of 8-ft. legs and caps, which measure about 12 in. in diameter, on top of which is placed about 18 in. of lagging, most of which is obtained from the lagging recovered from the back of the stope. This brings the over-all height of the set timbers to about 10½ ft. above the floor. The set timbers are then loaded with rock filling on the sides up to a height equal to the bottom of the chutes and braced. The timber is then removed from the back of the stope; the timbermen working from the top of the loaded set timbers starting at one end clean and prop the loose rock in the back as they proceed. The lagging recovered from the back is placed ahead on the set timbers to cover them as they advance; the blocking is thrown down the chutes to be used again elsewhere; the main timbers of the truss are used as props, if necessary—if not they are taken out through the set timbers on the level. By removing the back timber from on top the set timbers, the timbermen are right at their work. A plank or two about 2 ft. above the top of the set timbers on the stulls may be used once in a great while when the back of the stope is 18 ft. above the floor, to enable the men to remove the timbers from the back with more ease. The stopes are not mined to an excessive height above the floor.

Where the lower end of the stull is so low, as shown in the figure, that it would interfere with the erection of a set, the set is stood up on either side of the stull timber, which causes no inconvenience.

When the sides of the stope are bad, as shown in Fig 10, p. 812, of the JOURNAL of May 8, and they must timbered all the way down, this timber is recovered from time to time as the rock filling rises. The timbermen stand on the fill from which they work, the timber being hoisted.

H. H. HODGKINSON.

Franklin Furnace, N. J., June 9, 1915.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALKALIS—Process of Producing Chlorates of Alkalis and Alkaline Earths. Walter Laib, Rittman, Ohio, assignor to The Ohio Salt Co., Wadsworth, Ohio. (U. S. No. 1,143,586; June 15, 1915.)

ALUMINUM—Compound for Welding Aluminum and Aluminum-Containing Alloys. Erland Thaulow, Frederiksberg, near Copenhagen, Denmark. (U. S. No. 1,139,923; May 18, 1915.)

ALUMINUM—Treatment of Surfaces of Aluminum or Alloys of Aluminum in Order to Prepare them for Receiving a Metallic Deposit. Francois Auguste Roux, Paris, France, assignor to Société L'Aluminium Francaise, Paris, France. (U. S. No. 1,144,000; June 22, 1915.)

ALUMINUM NITRIDE—Process of Manufacture of Aluminum Nitride. Adrien Badin, Paris, France, assignor to Société Générale des Nitrures, Paris, France. (U. S. No. 1,143,482; June 15, 1915.)

ANODES—Process for Manufacturing Anodes of Manganese Dioxide Ore. Percy Claude Cameron Isherwood, Bushey Heath, England. (U. S. No. 1,143,828; June 22, 1915.)

ARSENATE OF LEAD—Method of Manufacturing Arsenate of Lead. Edwin O. Barstow, Midland, Mich., assignor, by mesne assignments, to The Cleveland Trust Co., trustee, Cleveland, Ohio. (U. S. No. 1,141,920; June 8, 1915.)

BRICK—Pure Kieselguhr Brick and Process for Making the same. Arthur Ch. Hesselmeyer, Chicago, Ill. (U. S. No. 1,143,826; June 22, 1915.)

BROMINE—Process of Making Bromine. Edwin O. Barstow, Midland, Mich., assignor to The Dow Chemical Co., Midland, Mich. (U. S. Nos. 1,141,921 and 1,141,922; June 8, 1915.)

CASTING—Automatic Metal-Feed for Continuous Casting Machines. Grenville Mellen, West Orange, N. J., assignor to Continuous Casting Corporation, Newark, N. J. (U. S. No. 1,139,888; May 18, 1915.)

CASTING—Guide for Continuous Casting Machines. Grenville Mellen, West Orange, N. J., assignor to Continuous Casting Corporation, Newark, N. J. (U. S. No. 1,139,889; May 18, 1915.)

CASTING POT. Grenville Mellen, East Orange, N. J., assignor to Continuous Casting Corporation, Richmond, Va. (U. S. No. 1,139,886; May 18, 1915.)

COMPOUND METAL ARTICLES, Process for the Production of. Byron E. Eldred, New York, N. Y., assignor to The Commercial Research Co., New York, N. Y. (U. S. No. 1,140,135; May 18, 1915.)

CONCENTRATORS—Combined Batea, Jig and Pan Motion Concentrator. Karl Senn, Alameda, Calif. (U. S No. 1,141,419; June 1, 1915.)

CRUCIBLE FURNACE. Emil Hallgren, Bellevue, Penn. (U. S. No. 1,138,866; May 11, 1915.)

CRUSHER—Rock Crusher. Edward H. Moyle, Los Angeles, Calif. (U. S. No. 1,142,116; June 8, 1915.)

CRUSHERS—Roll-Crusher. William H. Lieber, Milwaukee, Wis., assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis., a Corporation of Delaware. (U. S. No. 1,141,643; June 1, 1915.)

DISINTEGRATOR—Ore-Disintegrator. Leon St. D. Roylance, San Francisco, Calif. (U. S. No. 1,142,462; June 8, 1915.)

DISTILLATION FURNACES—Closure for Distillation Furnaces and Particularly Coke Ovens. Hermann Joseph Limberg, Gelsenkirchen, Germany. (U. S. No. 1,143,411; June 15, 1915.)

DRILLS, AIR—Jack Hammer-Drill. Samuel Oldham, Philadelphia, Penn. (U. S. No. 1,141,650; June 1, 1915.)

DRILL—Power Rock-Drill. Frederick Perley Porter, Kellogg, Idaho. (U. S. No. 1,140,185; May 18, 1915.)

DRILL—Miner's Drill. Samuel T. Skeen, Sandoval, Ill. (U. S. No. 1,140,077; May 18, 1915.)

DRILL-BIT CLUTCH. John W. Roby, Hammon, Okla. (U. S. No. 1,142,460; June 8, 1915.)

EXCAVATING MACHINE. Henry McDermott, Iron Mountain, Mich., assignor to McDermott Mechanical Co., Iron Mountain, Mich. (U. S. No. 1,139,690; May 18, 1915.)

FILTER-MASS WASHER. Joseph Kraus, Anaconda, Mont. (U. S. No. 1,139,776; May 18, 1915.)

FLOTATION—Ore Concentration. John W. Littleford, San Francisco, Calif., assignor to Minerals Separation, Ltd., London, England. (U. S. No. 1,142,822; June 15, 1915.)

FLOTATION—Separation of Mixed-Sulphide Ores. Henry Lavers, Surrey Hills, Victoria, Australia, assignor to Minerals Separation American Syndicate (1913) Ltd., London England. (U. S. No. 1,142,821; June 15, 1915.)

INGOT MOLD. Samuel E. Hitt, Elyria, Ohio, and Joseph L. Peyton, Washington, D. C. (U. S. No. 1,139,284; May 11, 1915.)

INGOT MOLD. Joseph L. Peyton and Samuel E. Hitt, Sydney, N. S., Canada. (U. S. No. 1,139,219; May 11, 1915.)

MINING MACHINE and Truck. Edwin R. Merrill, Columbus, Ohio, assignor to The Jeffrey Manufacturing Co., Columbus, Ohio, a Corporation of Ohio. (U. S. No. 1,142,348; June 8, 1915.)

OPEN-HEARTH FURNACE—James C. Davis, Hinsdale, Ill., assignor to American Steel Foundries, New York, N. Y. (U. S. No. 1,143,690; June 22, 1915.)

ORE-TREATING APPARATUS. Rubin Colvin, Park City, Utah. (U. S. No. 1,142,497; June 8, 1915.)

PERCUSSIVE TOOL. Lewis C. Bayles, Easton, Penn., assignor to Ingersoll-Rand Co., New York, N. Y. (U. S. No. 1,142,478; June 8, 1915.)

PIPE JACK. George F. Voigt, Charlestown, Ind. (U. S. No. 1,143,739; June 22, 1915.)

PNEUMATIC TOOL. Benjamin M. Carmina, New York, N. Y. (U. S. No. 1,142,671; June 8, 1915.)

PULVERIZER. Peter C. Forrester, West Tacoma, Wash. (U. S. No. 1,142,159; June 8, 1915.)

PULVERIZERS—Lubricating System for Pulverizers. Morris Benjamin, Atlanta, Ga., assignor to Benjamin Pulverizer Co., New York, N. Y. (U. S. No. 1,142,746; June 8, 1915.)

RADIO-ACTIVE ORES—Method of Treating Radio-Active Ores and Intermediate Products. Erich Ebler, Heidelberg, Germany. (U. S. No. 1,142,154; June 8, 1915.)

RADIO-ACTIVE SUBSTANCES—Manufacture, Isolation, and Enrichment of Radio-Active Substances by Adsorption from Solutions. Erich Ebler, Heidelberg, Germany. (U. S. No. 1,142,153; June 8, 1915.)

Manufacture of Nitrite of Soda

In a recent paper read before the Canadian section of the Society of Chemical Industry, James Turner said that of the various methods of converting sodium nitrate into nitrite, practical experience had shown that reduction by means of metallic lead was the method best adapted for working on a large scale. The reason was that both lead and saltpeter melted considerably below the temperature required for the reduction, and therefore the two substances could be brought into very intimate contact. By careful regulation of the process, 90% of the theoretical yield of nitrite might be obtained.

A process was patented in England in 1896 by Doctor Paul and Read Holliday & Sons, Ltd., for the reduction of sodium nitrate by means of caustic soda and sulphur. This process had not proved to be so cheap as the lead process, on account of the difficulty in separating the sodium sulphate from the nitrite, and the maximum yield was only 80% of theory.

Alite, the Mixture of Composition $8CaO$, Al_2O_3, $2SiO_2$, was found to possess a maximum melting-point, 1385° C., in the ternary system, $CaO - Al_2O_3 - SiO_2$, and it therefore probably represents a definite compound. It has a specific gravity 3.035, refractive index 1.63, and hardness 7 on Moh's scale. The substance known as alite, which crystallizes from cement clinker, exhibits all the properties of the above compound and it is maintained, mainly on optical grounds, that the substances are identical, according to E. Jänecke (Zeit. für anorg. Chem., Vol. 89, p. 335).

Mining Ore From a Caved Stope

By James E. Harding*

SYNOPSIS—Methods used in mining a block of ore which caved after a square-set stope started in it had burned. Waste filling was used and stulls turned tapering in lathe and placed butt end up were pulled by hydraulic jacks and reused.

A difficult problem of ore extraction was presented to the staff of the Mina Santa Francisca† in getting out ore from a stope on the 200 level which had caved in after a fire had burned out all the supporting timbers. This stope, started several years before, had been raised with square-set timbers from four to six sets above the level, when it caught fire and was necessarily abandoned. All the timbers burned and the stope caved in from above. The rock was very hard and siliceous and caved down in huge slabs, a fact which had much to do with the later method of working. In one or two places the eaves extended through to the surface, but were of very small dimensions. After a lapse of several years it was decided to make an effort to recover the ore which was known to remain in the stope.

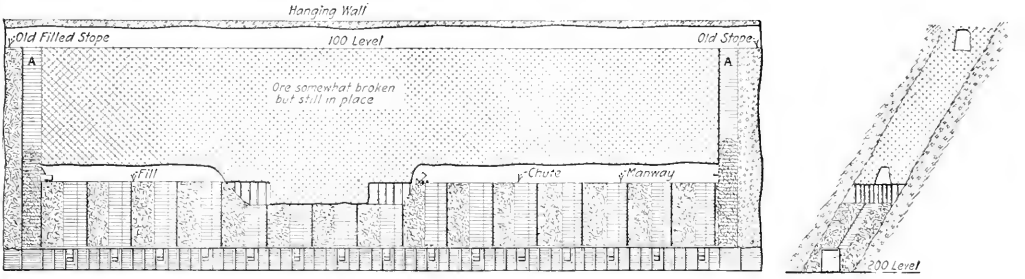
The difficulties of this undertaking were increased by the fact that either directly over the stope or in its immediate vicinity was located the entire surface equipment of the mine, including power plant, sampling mill, machine shop, offices, warehouse, sorting patio, ore bins and railroad tracks. In case of any extensive cave-ins, these buildings would be injured; and their removal entailed a prohibitive expense.

Thus in the consideration of various methods of working the stope, all methods which left a possibility of such happenings automatically eliminated themselves. The dimensions of the orebody were known to be about 20 ft. in width and 300 ft. in length. Square-setting was considered and rejected, first, because of the expense, and second, because it was impossible to obtain sufficient timber owing to interrupted traffic.

The mine was already excellently equipped with a system for waste filling whenever necessary. Previously an old shaft had been cleaned out from the surface to the 300 level and was used to convey the waste filling into the mine; this waste being merely shot into the shaft from a glory hole on the surface and allowed to run down, then drawn out from a chute on each level and conveyed in cars to the desired point.

The fact that plenty of filling was readily available within a very short tram from the stope largely determined the method finally adopted, which was a combination of overhand slicing and close waste filling.

The preliminary work consisted in driving the 100 level and redriving the 200 level through the burned and caved zone. At the same time, a raise with solid cribbing was carried up at each end of the ore to connect the two levels. This work was handicapped by the heat occasioned by the former fire. Little running ground was encountered and spiling had to be resorted to on only two or three occasions. One unexpected feature, however, caused considerable trouble. The rock, of course, was dry and dusty. This dust consisted largely of ferrous sulphate, which, getting in a man's nostrils, caused such violent sneezing that he was temporarily incapacitated, sometimes for several hours. Sponges and rubber nose guards were used, but these by no means prevented the trouble. Nevertheless, the connections were finally established and excellent natural ventilation soon rendered the working places comfortable.



Section Through Stope at Mina Santa Francisca, Showing Mining and Filling Method

As the work progressed on the 200 level, regular sill-floor sets were placed. These sets were made of 10x10-in. timber with posts 8 ft. 6 in. long, and caps 7 ft. long were placed 4 ft. apart in the clear. It may seem that this was unnecessarily close timbering, but remembering that no chances could be taken of caving the surface, it seemed advisable. At the time the timber was placed, chutes of 3x12-in. plank were built in every fourth set. The levels and raises being completed, the real work of taking out the ore began. Starting from both ends of the stope on both sides of the sill-floor timbers, a room as high as the sill-floor timbers was taken out across the vein. As fast as this ore was taken out stulls and headboards were placed in position to support the back.

One very special feature of this work was the use of these stulls, which were specially selected, straight-grained, hard pine, cut green and seasoned, about 10 ft. long and about 8 in. in diameter at the small end. They were placed in a lathe and turned down to round with a 2-in. taper from butt to tip and put in place always big

*Mining engineer, Vantrent, Calif.; recently foreman, Mina Santa Francisca.

†An A. S. & R. Co. property, situated at Asientos, Ags., Mexico.

end up. The reason for all this precaution and trouble will appear later.

The raises A at the ends of the stope were filled with waste, and whatever waste was encountered in the ore was thrown behind. Filling was drawn out of the waste raises to fill the first room close up to the face, burying the stulls and being stowed to the walls and close to the back. When the distance from the waste raises prohibited shoveling, a chute was placed in the cribbing of the waste raise and a track laid upon the caps of the sill-floor sets. A small drift was also carried through the rock above the sill-floor sets to permit the passage of a mine car, and thus the work was carried on until eventually the sill-floor slice was all taken out and filled.

Then work was begun on the second slice in exactly the same way as before. A room was started around the extreme end chutes and worked out first around the chutes in the direction of the waste raise and filling drawn in. As soon as this room was worked out half way to the other chute, it was filled and abandoned, the work being taken up at the next chute in the same way as before. While taking out the second slice, all of the stulls put in while working out the first slice were encountered with their large ends sticking up out of the fill. All were very easily pulled with a hydraulic jack, owing to the way in which they had previously been prepared and placed.

When the work of taking out ore from any particular room was abandoned, the chute and manway were built up to the back before filling. It was deemed advisable to carry a manway up with each chute to make each room more accessible and also to make escape easy in case of any accident. The waste drift and track followed closely and the open ground between the face and fill was never allowed to exceed 10 ft. in width, and sometimes in case of exceptionally loose ground was carried much closer than that. In this way the few slight caves which started soon stopped themselves.

The illustration shown on p. 71 in the strike and dip section gives a clear idea of the work. Unfortunately the strike section shows practically every stick of timber used in the work, and from its appearance gives an idea of a far greater ratio of timber to fill than actually existed. However, an examination of the dip section shows this ratio more clearly and gives a better idea of the footage of timber necessary to the ton of ore produced.

The stulls were used over and over again and practically all the timber buried and lost was that used along the level on the sill floor, chutes and manways, and a few planks used to hold back waste in the rooms.

New Map of Pittsburgh

The Pittsburgh Industrial Development Commission, Pittsburgh, Penn., has completed an industrial map of the Greater Pittsburgh district. The map is 4x6 ft. and is printed in four colors. It shows all streets, parks, roads, railroads and street-car lines, and every manufacturing plant in the district having railroad connections. It covers a territory extending from Verona on the north to Mt. Oliver on the south and from Wilmerding and McKeesport on the east to Emsworth and Neville Island on the west. Included is an insert map covering an area of 53 by 65 miles, from Butler and Vandergrift on the north to Follansbee, W. Va., on the south and from Greensburg on the east to East Palestine on the west.

June Mining Dividends

Dividends paid in June, 1915, by 38 United States mining companies making public returns amounted to $10,590,656, as compared with $7,410,317 paid by 31 companies in June, 1914. Industrial and holding companies allied to mining paid $7,432,952, as compared with $12,915,007 in 1914. Canadian and Mexican companies paid $355,268 in June, 1915, and $1,018,580 in June, 1914.

The totals for the first six months of the year 1915 are as follows: Mining companies, $26,001,044, as against $32,925,883 in 1914; metallurgical and holding companies, $34,164,152, as against $11,714,103 in 1914; Canadian and Mexican mines, $4,535,622, as against $9,894,912 in 1914. The accompanying table shows details of the month's payments:

Whatever may be the general state of business of the country, the rising tide of prosperity in mining circles is shown by the increased dividends of Ahmeek, Chino, Butte & Superior, Nevada Con., North Butte, Old Dominion (both mining and holding companies), Osceola, Quincy, Ray Con. and Utah Copper.

Du Pont Company Wins Decision

The United States Circuit Court of Appeals, on July 2, at Philadelphia affirmed the verdict rendered in the Federal District Court in the case of the Buckeye Powder Co. against the E. I. du Pont de Nemours Powder Co., Eastern Dynamite Co., and the International Smokeless Powder Co. The action against the du Pont concerns

was to recover $4,000,000 for alleged violation of the Sherman anti-trust act. It was charged that the defendants stifled competition in the manufacture and sale of black blasting powder. The evidence produced did not sustain the charges.

Volcano, a New Nevada Strike

By Francis Church Lincoln*

The new mining camp of Volcano is situated 18 miles east of Tonopah. It is within the forest reserve and upon an old road used in the early days for hauling fuel wood to Tonopah. Leaving Tonopah by the main highroad to the east, one crosses the Tonopah hills near the Belmont mine and comes to the Ralston Desert. Here the road to Manhattan branches to the left and the road to Ely to the right. Looking toward the north, the mountains at Manhattan and Belmont can be seen and toward the south, those at Goldfield. Across the Ralston desert, in the low hills on its eastern boundary, Volcano lies at an elevation of 6300 ft. Although in a forest reserve, there are no trees in the neighborhood of the original strike and few elsewhere in the district.

The first strike was made on Apr. 18, 1915, by John Musser and Charles Glenn, who traced some rich float to its source. A second discovery was made by Ed McKelvie on May 7, about two miles from the first strike at a camp which is now called Sylvanite. At both of these camps are encountered in irregular bunches. A piece of this silver ore, which did not show horn silver, was found to contain 12.08 oz. silver and a trace of gold.

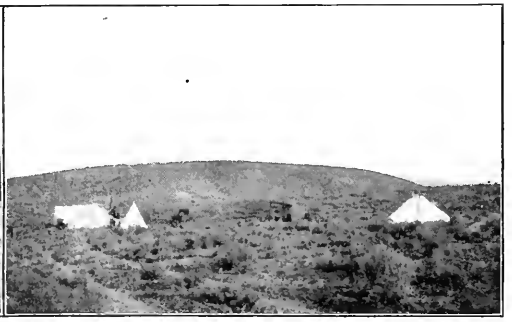
The country rock at Sylvanite appears also to belong to the rhyolite group, although it is not so fine-grained as that at Volcano. The ore contains horn silver. An assay of specimens of this ore gave 64.68 oz. of silver and a trace of gold; and the average grade is said to be between $15 and $30. The vein in which the ore occurs strikes north 25° West magnetic, and dips 80° toward the northeast. At a depth of 10 ft. the width of the vein is 2 ft.

The camp at Volcano is typical of the new strikes which are continually being made in the various parts of Nevada; some of them develop into paying mines. At the present time not sufficient work has been done to determine whether the values will persist in depth.

Removal of Rust by Chemicals

For a variety of purposes it is eminently desirable to find some chemical reagent that will readily remove rust from iron. In many cases the loss of a little iron along with the rust is not of importance, but on the other hand, in the cleaning of specimens for museums, it is important to lose as little iron as possible. Of course, in scientific investigations which have for their object the quantitative determination of corrosion by weighing the iron before and after attack, it is essential that the loss of unoxidized metal be reduced to the absolute minimum.

Original Discovery at Volcano



First Camp at Sylvanite

tent settlements have sprung up and also at the well near the Sylvanite camp. It is interesting to note that old workings are situated only a short distance from the present strike at Sylvanite, and that rather extensive workings occur within a few hundred feet of the original strike at Volcano.

The country rock at Volcano is rhyolite. When this fine-grained rhyolite is freshly broken it emits a strong odor of hydrogen sulphide. The ore is a dark quartz showing free gold. The dark color of the quartz is caused by the presence of silver sulphide. This ore is about a foot in thickness and has a strike of about 85° East magnetic, dipping roughly 30° toward the south. An assay of specimens of this ore, made at the Mackay School of Mines, gave 270.04 oz. silver and 13.44 oz. gold per ton. The average grade is said to be better than $200 per ton. In the hanging wall of this vein silver chlorides

*Reno, Nev.

The subject has been reviewed by J. Newton Friend and C. W. Marshall in an article published by the British Iron and Steel Institute.

The authors explain that electrochemical methods have frequently been suggested, the rusty iron being suspended as cathode in a suitable electrolyte, the anode consisting of some inert material such as carbon or platinum. By adjusting the current density, the hydrogen set free at the cathode appears to loosen the rust by what is asserted to be a purely mechanical process, not involving the solution of any iron; and for such processes considerable accuracy is claimed. Scraping with knives and polishing with sand or emery paper or cloth has been the process usually adopted for small specimens, and the method has proved satisfactory. For large test pieces these methods will not do.

In the literature on the subject, different investigators have frequently alluded to dilute solutions of sodium

citrate as suitable media for loosening rust without dissolving any iron. A series of experiments was undertaken to prove this and to extend the inquiry to the action of other chemical reagents upon rusty iron.

The metal chosen for the tests was mild openhearth steel sheets, cold rolled and charcoal annealed. They were 2x1 ft. in area and 22 B.w.g. in thickness. Several of the sheets were soaked in water and exposed to the air for a month, after which they appeared to be corroded equally over their surfaces. They were then cut up into squares measuring $2\frac{1}{4}$x$2\frac{1}{4}$ in., weighing approximately 19 grams. In order to further insure uniformity, the results obtained with the small plates were compared with one another only when they had been cut from the same large sheet. The plates contained approximately 0.2 gram of hydrated ferric oxide in which there was only the merest trace of ferrous iron. Several of the plates were thoroughly cleaned with emery paper, an even loss in weight being taken as a standard for comparison with the result obtained by chemical means. The accompanying table shows the degree of accuracy which may be expected, noting the losses of weight with small plates cut from the same sheet:

PLATES CLEANED MECHANICALLY

	Sheet 1 Gram	Sheet 2 Gram.
Plate 1	0 2495	0 1772
Plate 2	0 2347	0 1682
Plate 3	0 2336	0 1718
Plate 4	0 2398	0 1628
Mean	0 2394	0 1700

Solutions of sodium citrate were used, in 1, 2, 5, 10 and 20% solutions, the results being shown in the accompanying table:

RESULT OF CLEANING WITH SODIUM CITRATE

Loss in Weight of Rusty Plates

Days	1 Gram.	2 Gram.	3 Gram.	4 Gram.	5 Gram.
3	0 1248	0 1576	0 2266	0 2770	0 3810
4	0 1746	0 2100	0 2718	0 3260	0 4326
5	0 2110	0 2334	0 2994	0 3576	0 4574
6	0 2412	0 2534	0 3218	0 3714	0 4764
7	0 2942	0 2738	0 3474	0 3874	0 5048
8	0 3802	0 3160	0 4146	0 4258	0 5598
Sodium citrate.	1%	2%	5%	10%	20%

Next solutions of boric acid were used, ½, 1, 1½, 2 and 3½%, the last named being saturated. The table shows the loss of weight in the plates at different times in these solutions. Various other chemical reagents were tried, but none of them proved as useful as boric acid, and it did not appear possible to find a reagent that would remove rust quantitatively without also dissolving some iron. A 10% solution of aluminum sulphate cleaned the iron in 24 hr. and yielded an excellent metallic surface. A 1% solution of chromic acid removed rust exceedingly slowly, a plate of metal not becoming clean in six weeks, during which period it had lost 0.2448 grams in weight.

RESULT OF CLEANING WITH BORIC ACID

Loss in Weight of Rusty Plates

Days	1 Gram.	2 Gram	3 Gram.	4 Gram.	5 Gram.
1	0 0472	0 0890	0 1622	0 1968	0 3260
2	0 1242	0 1044	0 1646	0 1990	0 3566

4	0 1742	0 1984	0 1736	0 2100	0 3620
7	0 3060	0 3400	0 2720	0 2184	0 3690
11	0 3742	0 3857	0 3584	0 3742	0 3878
14	0 4002	0 4131	0 3614	0 3764	0 4054
Boric acid	0.5%	1 0%	1 5%	2 0%	3.5%

Saturated solutions of zinc sulphate and of magnesium chloride were also tried. In the former the rust turned black; and signs of cleaning were apparent in the latter only after 11 days. A 10% solution of ferrous sulphate cleaned a piece of iron in a fortnight, the loss in weight being 0.4588 grams. An attempt was made to clean some plates by immersing in 5% caustic-potash solution in contact with granulated, and in some cases powdered zinc, the surface of the plates being scratched free from rust in places to insure good contact. The rust was converted into a blackish mass containing a high percentage of ferrous oxide, but no satisfactory cleaning action was observed. A plate of pure iron foil (Kahlbaum's), entirely free from rust, when immersed in caustic-potash solution in contact with the zinc, slowly gained in weight after the first day.

Formation and Distribution of Bog Iron-Ore Deposits*

The simplest cause of precipitation of iron is oxidation from the soluble ferrous to the much less soluble ferric compounds. Ferrous carbonate, soluble in carbonated waters, is also precipitated as the carbonate by evaporation of the excess CO_2. Certain bacteria precipitate iron by building the hydrated oxide into their body cells. Iron is precipitated as the sulphide when vegetation decays in the presence of sulphates of lime and magnesia, with a deficiency of oxygen. There are many other means by which, under special conditions, iron may be precipitated in nature. Oxidation, evaporation of CO_2 and iron bacteria have usually been held to be most important.

Bogs are often accompanied by thin layers of iron ore consisting largely of hydrated ferric oxide, frequently with considerable amounts of ferrous carbonate and sometimes ferrous sulphate and silicate. In marine marshes, under the influence of the sulphates of sea water, iron may go down as the sulphide. Bog ores, however, consist essentially of limonite with subordinate amounts of carbonate. Such ores are usually high in phosphorus and almost invariably preserve abundant fossil fragments of leaves and plant remains which serve to identify them as of bog origin.

Northern Deposits

Those countries best known as producers of bog ores are Norway, Sweden, Germany, Poland, Finland, and Canada. Many deposits occur in the northern United States. Careful examination has shown that the overwhelmingly large number of the known bog deposits occur in the northern portions of the three northern continents.

A very small percentage of our bog-ore deposits is to be found outside the glaciated regions, while within those regions they are characteristic and abundant, both in Europe and in North America. The ores accumulate in the smaller swamps, while in large neighboring morasses they may be entirely wanting, probably by reason of the fact that the concentration is greater in the smaller swamps. Glaciated areas are more favorable to iron accumulation because they present numerous small swamps, rather than the immense ones, such as are common to the lower flood plains and deltas of large rivers or the saline marshes of low coastal plains.

Another factor, doubtless, is the proximity of available sources of supply for the iron. From 1 to 3 per cent. of

*Abstract of paper to be presented at the San Francisco meeting of the A. I. M. E., September, 1915, by C. L. Dake, Assistant Professor of Geology, Missouri School of Mines.

the glacial drift is said to be made up of magnetite; and other iron compounds are present. The unconsolidated condition of the drift renders this iron content easily accessible.

Tropical Deposits

The prevailing red color of soils in the tropics has been assumed to be a result of a higher oxidation of the iron and its superficial dehydration. It seems possible that the rapid decay of vegetation in tropical regions and the resulting lack of accumulation of partly decayed vegetable matter may effect the accumulation of bog iron ores.

Two alternative suggestions have been tentatively advanced. First, that iron does not go into solution in the tropics as abundantly as in colder regions; and secondly, that it goes into solution abundantly, but is not so readily precipitated.

Most tropical soils, by reason of long, hot, dry seasons, are deficient in humus and contain iron in a high state of oxidation, and therefore are relatively insoluble. But regions of nearly continuous heavy rainfall are covered with rank vegetation, and rapid decay yields plentiful humus. In such regions, therefore, iron may go into solution freely, but the abundant rains will cause excessive leaching of the humus, removing the dissolved iron. Thus tropical soils may, on the average, be low in humus, while the rivers carry, nevertheless, much organic matter and hold iron in solution. The high state of oxidation of the iron as a whole, together with the extensive leaching of such iron as is soluble and its rapid removal in waters with a high solvent power, together with the absence of small swamps giving opportunity for concentration, may possibly furnish a partial explanation of the infrequent occurrence of bog ores in the tropics.

Lake ores, described as occurring chiefly in Sweden, Finland, European Russia and Canada, may be classed with bog ores, since they are essentially the same in distribution, method of formation and character, and frequently show graduations into bog ores.

Summary

Bog ores are widely distributed, but occur chiefly within the colder temperate regions and for the most part within the glaciated area. No important deposits are known to be forming in marine bogs.

The probable causes of this distribution are:

1. Swamps are more numerous in the glaciated area than elsewhere.

2. Glacial swamps are of smaller size and allow greater concentration of chalybeate waters.

3. There is abundant available iron in glacial soils.

4. Possible climatic factors involve the high state of oxidation of the iron in warmer regions, together with the lack of iron solvents in large areas of tropical soils and abundant organic matter in many of the rivers, keeping in solution the iron once dissolved and permitting it to be carried out to sea, instead of being redeposited in swamps.

The writer believes that glaciation is probably the most important factor, operating through the favorable conditions presented by the presence of numerous small swamps and the abundance of iron available in glacial soils.

[The original paper has 39 citations covering a wide range of authorities.—Editor.]

Chronology of Mining for June, 1915

June 1—Lower lake freight rates on iron ores became effective.

June 2—J. P. Morgan & Co. announced purchase of $10,000,000 of 10-year 6% bonds of Kennecott Copper Corporation.

June 3—Decision adverse to the Government in its suit to dissolve United States Steel Corporation rendered by the Federal District Court at Trenton, N. J.

June 4—Appellate Division of the New York Supreme Court rendered decision in favor of plaintiff in case of A. Chester Beatty vs. Guggenheim Exploration Co.

June 7—Amalgamated stockholders' meeting in Jersey City voted for dissolution of company.

June 8—Decision, as to motion to dismiss, favorable to Government in six suits pending in California against Southern Pacific Co. in oil-land cases.

June 9—Ohio Copper Co. leased mine and mill to General Exploration Co.—The Tonopah Merger and Tonopah Victor mines voted to merge with Tonopah Extension.

June 10—Cave-in in Longacre Chapman mine, Joplin district, buried six men; four rescued after 120 hours' imprisonment.—Flywheel at mill of Mine La Motte burst, doing considerable damage and injuring several men.

June 12—Calumet & Hecla distributed bonus of over $500,000 among nearly 10,000 employees.

June 14—Stores in Butte forced to declare holiday on anniversary of big Butte labor riot in 1914 on account of action by clerks' union and defection in employers' association.

June 15—Fire destroyed machine shop and equipment of Conrey Placer Co., at Ruby, Mont.; loss, $125,000.—Last spike driven in Mascot & Western Ry., Arizona, connecting Mascot copper mines with Southern Pacific Co.

June 16—Greene-Cananea resumed operations at mine and smeltery with two blast furnaces and one reverberatory.

June 18—First section of Ohio copper mill started by lessee.—First copper produced at Cananea after long idleness.

June 21—Earthquake in Imperial Valley, California, did considerable damage.

June 22—Disruption of the International Lead Convention owing to secession of the Australian producers.—United States Supreme Court decides against Lackawanna in coal-ownership cases.

June 23—First copper made at Chuquicamata.

June 24—Success Mining Co., Idaho, changed hands by sale of 1,100,000 shares of stock for $1 a share.—Unexplained accident wrecked shafting in west half of Washoe concentrator, necessitating 24-hr. shutdown of Anaconda's Butte mines.

June 28—Strike of zinc miners in Joplin district, Missouri.

June 29—Portland Gold Mining Co. given possession of Stratton's Independence.—First section of Inspiration mill put in operation.

June 30—Miami increased its dividend to 75c. quarterly.—Sterling exchange touched 4.7575, the lowest in 40 years.

Editorials

New Jersey Zinc Co.

The real Croesus among the zinc companies is the New Jersey Zinc Co. This company owns the marvelous Franklin mine, affording an ore that makes the high-grade spelter, which realizes the highest price. Conquently the New Jersey company gets all there is in this business without division among other interests. Besides this it has an extensive Western smelting business, which is now immensely profitable, and some important Western mining interests. As if this were not enough there is the spiegeleisen business in the East, which also has become exceptionally lucrative.

Even in normal times the New Jersey Zinc Co. was a bonanza. Previous to 1912 it is said to have paid $30 per share annually on its 100,000 shares, and in 1912 to 1914 reports say that its dividends were $50 per share per annum, besides which a cash surplus of about $25,000,000 was accumulated. This week the company is increasing its capital stock from $10,000,000 to $35,000,000 and cutting one of the biggest melons in corporate history for distribution among its shareholders.

The spectacular success of the New Jersey Zinc Co. is based primarily upon two things; namely, the possession of the phenomenal Franklin mine and the Wetherill process of magnetic separation. The Franklin mine is a unique deposit of mixed zinc, iron and manganese minerals which previous to about 20 years ago was exploited with only moderate success. Then John Price Wetherill introduced his process of separating the component minerals in a more effective way than ever before. August Heckscher consolidated conflicting property interests, and the new company set out upon its wonderful career. Profiting by its long and successful experience and its efficient organization, it went into the mining and smelting business in the West, operating there as the Mineral Point Zinc Co., the Prime Western Spelter Co. and the Empire Zinc Co. At present it is probably the largest zinc mining and smelting company in the world, and certainly it is the most profitable.

Selling Copper for Export

The war is without doubt destined to change more than one custom in the copper trade. Among these is the influence that the speculative market for "standard" copper in London has had on our market for refined copper. In previous times the existence of that market has enabled arbitrage transactions to be made whenever the two markets were out of joint, but recently the British restrictions have prevented any such operations to any important extent, and when the difference between the price for "standard" copper and the nominal quotation of the London Metal Exchange for electrolytic spread to £14 per ton, the absence of any broad commercial meaning to the fluctuations in the price for "standard" copper became self-evident. There should never be a difference in excess of about £2½, for at that discount refiners should easily be able to buy up all the "standard" copper and turn it into electrolytic. Of late, however, foreign refiners have been excluded from the "standard" market by the governmental restrictions against the export of copper.

For the time being, anyway, and perhaps for longer, no attention need be paid to the fluctuations of "standard" copper in London. Rises or falls are neither bullish nor bearish points, for they have scarcely anything to do with the real movements in the trade for the metal.

Another time-honored custom that has been upset to a considerable extent—and will be abolished, it is to be hoped—is the selling of copper for export in terms of foreign money—pounds sterling in London, francs in Paris, etc. At least one of the important American producers is now selling only on the basis of dollars. Its prices include freight, insurance, etc.; that is, they are made in terms of dollars and cents, c.i.f., and this producer says it will never again sell in terms of foreign money.

A factor contributory to this innovation is the uncertainty with respect to the future of sterling exchange. The producer selling copper for delivery two or three months hence is now unable to judge closely what he is going to realize if payment is to be made in pounds sterling or francs, inasmuch as sterling exchange may fall in the meanwhile to 4.70 or lower. If sales be made in dollars there is of course no risk in this respect. Anyway, the dollar exchange in this market is further to be commended by the fact that after all it is an American market, about 70% of the copper production of the world being supplied by American refiners. The JOURNAL would like to see the custom of the trade modified one step further, would like to see copper quoted only in terms of cents per pound, cash, in New York and the rest of the world compelled to buy here on our own terms. However, this is too much to expect right away, for our copper producers, in their competition among themselves and with those of the rest of the world, will no doubt feel themselves obliged to court their customers by naming a price delivered to them or to some port with which they are familiar. Nevertheless the method of doing business with them may be altered if Congress next winter makes such a declaration of the Sherman law as will render it clear that it was not intended to apply to combination among sellers in foreign markets. The arguments upon this point at the recent hearing of the Federal Trade Commission were impressive, and there is reason to believe that Congress will view favorably that which exporters want it to do; that is, make it positive that concerted action in foreign business is not contrary to the Sherman law.

John D. Ryan made the following illuminating remarks about the way the business of American producers in selling copper for export has been conducted heretofore:

The business has been done in foreign countries largely with foreign dealers who made combinations, withheld their business when there was any overproduction or when there was any chance of making or breaking the price, who manipulated the speculative markets for copper abroad, who kept the actual consumers out of the market and prevented their buying until such time as they had driven the price about as low as they thought it could be made. Then they bought all that they could buy of us, and when they got through buying the domestic consumer, who never was allowed to combine with others and who had to cover his demands, followed them along, and as a result paid seven-eighths of a cent a pound more.

I know by our own experience. We sell large concerns in Europe. It is a daily occurrence to get a cable from our representative saying that so-and-so is in the market for a thousand tons or three or four thousand tons or whatever the quantity is, and will give us the business on equal terms with "A," who is our competitor and whom the buyer represents as bidding 10 shillings under us. Now, "A's" office is only two blocks from my office here, but I don't dare to call him on the telephone to ask whether that consumer in England or in Germany is telling the truth or not. I might be violating the law. The chances are nine out of ten that the foreign consumer is not telling the truth, but is simply telling our representative that somebody is quoting 10 shillings under him for the purpose of trying to bring our man down to the basis of the quotation he wants. But we fight one another, and the consequence is that the buyer gets the advantages. We cannot even compare notes as to what our prices are.

It is not unlikely that a change in American laws that will better enable American copper producers to meet the situation that Mr. Ryan has so lucidly described will be another one of the innovations that will date from this period of upheaval.

The Plaint of the Prospector

Now and again we receive communications from prospectors which as a rule are valuable only in that they are human documents filled with sentiments which truly come from the "heardt oudt." We have one such now in hand, complaining of the high cost of beans, bacon and flour, and the JOURNAL subscription, and setting forth in several foolscap pages his reasons for believing that the ore finder, the prospector, is the man, and technical journals should devote a larger share of their columns to his welfare. He cannot understand why an agriculturist can negotiate a considerable loan at the bank, secured only by his undeveloped ranch land, before a crop has been raised, while the prospector cannot raise a loan at the bank on his mining claim, not even after he shows a considerable vein. He says he is not taking any journal now because he is "perfectly aware of the best places to strike for the ore, and it is quite plain sailing, and what I need is plenty of powder and grub." All of which is the usual plaint of the prospector.

The prospector leads a most picturesque life, when viewed from a comfortable office in a New York skyscraper; but out on the side of a hill, miles from any other habitation and many miles from a population of any size; in a rough board shack, with the walls pasted over with newspaper to keep out unwelcome drafts and to take off some of the rough bareness of the room; with a bare or oilcloth-covered table in the corner with bottles of condiments and the sugarbowl covered over with a towel, long since dirty; with a woodbox filled with knots from the scraggly pines on the hillside; with an unattractive and not very comfortable bed in one corner, loaded with dark-colored bedding that has not been moved from around the nest formed by the sleeping body for months; with only a mangy cat for company, and with his latest literature dated perhaps a year back—the picturesqueness of the prospector's existence is completely swept away, and he deserves much sympathy in many ways.

But this particular wail contains its own best answer. If the prospector would discard his pre-glacial literature and read the current journals he would know where to go with his orebodies when he has assured himself of their existence, and he would find a wealth of information about the various mining districts old and new, mining development past and present, which would make his search for a new prospect more expeditious and the result more satisfactory.

Labor Troubles in Mining

What is going to happen in the actions of the labor unions with respect to the mining industry is one of those things that Lord Dundreary used to say "no fellah can find out," or figure out. The Coeur d'Alene, which used to be the scene of turbulence, the dynamiting of mills and the reversion to martial law, has been peaceable for a good many years. On the other hand, the Lake Superior copper region, which for half a century was regarded as the Altruria of the mining industry—the happy land of both magnate and miner—surprised everybody two years ago by becoming the locus of one of the most virulent strikes on record. Mystification over the outbreak of these miners of a relatively permanent population—as compared with the migratory workmen of the Far West—is not cleared away by the knowledge that they were stirred up and misled by professional agitators, or by the knowledge that the same people who in 1913 were reviling Mr. MacNaughton as the root of all evil were in 1915 contributing their dimes to give him a testimonial befitting his position as the benefactor of his workingmen. Nay, it will ever remain a mystery how the aforesaid workingmen could so suddenly have been locoed. Of course there was never any mystery about the parts of Moyer and his coadjutors, of the congressional committee of investigation, and of Brother Wilson who sits at President Wilson's cabinet table.

Lake Superior thus having fooled everybody, it remained for Butte in the following year to refute all prophets in the opposite way. From time immemorial Butte was the center of unionism—the place where the war chest was filled for battles elsewhere. Even the Lake Superior strike was financed to a large extent from the contributions of the Butte union, and looking at Butte everybody said, "What a pity the mining companies should be so under the domination of the union, not daring to call their souls their own. If there should be any resistance there would surely be doings in Butte." And everybody was looking for that to happen some day and was looking for the very Armageddon of labor wars.

Well, last year there were doings in Butte, but they were between rival labor unions, not between labor and capital, and the unions immediately made themselves ridiculous and were laughed out of popular consideration. The easiest way to get rid of an annoying person is to give him an opportunity to make an ass of himself if he has any disposition that way; and the same expedient proved to be very effective with labor unions.

The next result of the humorous developments at Butte was to show the miners of that place—who were supposed to be terrible swashbucklers, but in reality were merely honest, hard-working men (like most people)—that they

did not need any union whatever. Then the joke was fastened on the professional labor leaders, and to them it was a ghastly joke, for it raised visions of their having to go to work with sweating brows, just like their whilom dupes. Their efforts to revive the unions have so far been unavailing, as related last week by the JOURNAL's Butte correspondence in the following illuminating paragraph:

When the old Butte Miners' Union surrendered its Western Federation charter, it revived itself as the Butte Miners' Union and solicited members among the miners who are opposed to Moyer. The union has been going it alone nearly two weeks and has succeeded in getting a membership of about 40. Moyer's federation agents have been working to get members back into the fold for six weeks or more and are now operating under the name and charter which the old union surrendered, but in six weeks they have obtained only about 200 members, and that seems to be about the limit of the federation sympathizers. Then there is the original rebel organization of I. W. W.'s, the Butte Mine Workers' union, which still maintains an organization through a few officers, but has no members. There are more than 12,000 miners working in the Butte district again, and the results of the efforts to organize unions indicate that the men who work with their hands are satisfied to stay on the outside and that they have no particular sympathy with the men who work with their jaws only. The miners are getting their $4 a day, and they have neither union nor contract to enforce the payment, but they find that the employing companies are a pretty decent lot of corporations and will do right if permitted to do it.

Evidently the miners of Butte have perceived that there is no use in paying dues that do them no good, but support parasites who "work with their jaws only."

The third paradox in the affairs of mining labor is now before us in the Joplin district, where a strike is in progress, and whither the agitators are hurrying hot-foot. The motives for the strike are simple enough. The operators have been making extraordinary profits through the unusually high price for zinc ore, and the miners think they ought to participate in them to a greater extent than has been granted them. It is out of the ordinary, however, for Joplin miners to strike in a large body, to enforce the closing of mines where the men want to work, and to listen to the advice of professionals like Moyer. Heretofore Joplin has been noted for its freedom from unionism and for the independence of its men, who have been notorious strikebreakers in Colorado and elsewhere. However, a reversal of form on the part of the Joplin men is no more surprising than what was witnessed last year in Butte and in the previous year at Lake Superior.

BY THE WAY

On each copy of the latest bulletin of the Institution of Mining and Metallurgy is the following paster:

Notice—All members, associates or students of the Institution of Mining and Metallurgy, of German, Austrian, Hungarian or Turkish nationality, are hereby requested to abstain from attending any meeting or visiting the house of the Institution during the continuance of the war.

⁂

The supply of rifle cartridges available for use in Mexico is said to be very small, owing to the attention of cartridge manufacturers being diverted elsewhere. This class of ammunition is now quoted at 6c. per cartridge, f.o.b. El Paso. Real money now being scarce in Mexico, the warriors are experiencing great difficulty in keeping their belts well filled, though a few of the mines are being worked for this purpose. If one cartridge costs 6c., gold, how much does it cost in Villista paper to kill a man in battle?

⁂

An interesting story is told of a peculiar "practical" mining incident which occurred in one of the Mexican states some years ago. The superintendent of a mining property induced his friend, the federal mining agent, to let a denouncement of an "abandoned" mine slip through in spite of the fact that the bullion output from the property had been uninterrupted. As the operation of the mine yielded continually increasing profits, the advisability of securing the "good will" of the governor of the state became apparent. The said governor had been a sandal-footed bandit in the days when Porfirio Diaz roared about the hills in search of loot and glory, but many years of prosperity had educated him to the point where he was quite a stickler for ethical proprieties and legal formalities. In fact, he was about as particular as some New York or Philadelphia corporation lawyers. The matter was adjusted by Don Daniel taking the governor's personal note for the sum of money which changed hands. "A gentlemen's agreement" was entered into, verbally, to the effect that Don Daniel should never present the note for payment. Don Manuel was never dunned for the amount, but after his death the practical American miner cashed in on the note, thus depleting the late governor's estate not only for the total amount, but with interest at six per cent.

⁂

Reported in New York

The increase in the Miami dividend from $0.50 quarterly to $0.75 was rather unexpected, but was in line with the increases that had previously been made by the Utah, Nevada, Anaconda and other companies, which reflect the increased earnings of the copper-producing companies and exhibit confidence in the future of copper.

⁂

In the suit brought against the Reading companies for violation of the Hepburn clause of the Interstate Commerce law, the United States Circuit Court at Philadelphia has decided in favor of the companies. The court holds that the Philadelphia & Reading R.R. Co. does not own the stock of the Philadelphia & Reading Coal & Iron Co., the stocks of both being held by the Reading Co., a distinct organization. The relations between the coal and the railroad companies are simply those of miner and shipper on the one hand and of common carrier on the other. It is understood that the Government will take an appeal in the case.

⁂

Kennecott Copper, the owner of the Bonanza mine, in Alaska—originally an enterprise of J. P. Morgan & Co. and the Guggenheims, with whom Kuhn, Loeb & Co. subsequently became a partner—was recently listed on the Curb market, the purpose being manifestly to bring in the public. It is rumored that the distribution of the stock is being managed by an important operator, with the usual accompaniments of private tips and public press notices. Anyway, the stock had a sharp rise within a few days of its introduction. This of course attracted the attention of speculators, some of whom got in and out at a profit, while others without doubt will overstay their market and become involuntary investors. This is the usual way of a promotion.

Jones Mixer Suit Finally Decided

At Philadelphia last week the protracted patent litigation between the Carnegie Steel Co., complainant, and the Cambria Iron Co., defendant, entered its final stage when Judge McPherson of the Circuit Court of Appeals affirmed the decree of the Western District Court against Cambria, and ordered it to pay costs in the appellate court, the costs in the district court to be awarded by that tribunal. The question decided related to the method of accounting for profits earned by the infringement.

The decree of the lower court ordered Cambria to pay to the Carnegie company $586,306, with interest from May 1, 1912, to date of payment. The suit grew out of the Jones patent, granted for an improvement in the method of mixing molten pig iron, and charged the Cambria Iron Co. with infringement. Judge Buffington, then sitting on the Western district bench, sustained the validity of the claim and held that the process used by the Cambria works was an infringement upon the Jones patent. The suit has been in the courts for several years.

Dome Mines Report for 1914

The report of the Dome Mines Co., Porcupine, Ont., for the year ended Mar. 31, 1915, shows that 248,550 tons of ore was treated, which yielded $1,055,496, or $4.25 per ton of ore. The following table will show the financial affairs of the company during the year:

Receipts from bullion	$1,055,496.78
Receipts from interest, discount, etc.	6,878.41
Total receipts	$1,062,375.19
Charges:	
Mining	$205,492.20
Milling	248,407.38
General	114,816.89
Selling expense	5,160.21
Development	173,319.02
Additional construction and equipment, less salvage	106,792.49
Written off buildings and equipment	29,808.55
Total charges	$883,796.74
Balance of receipts	178,578.45
	$1,062,375.19

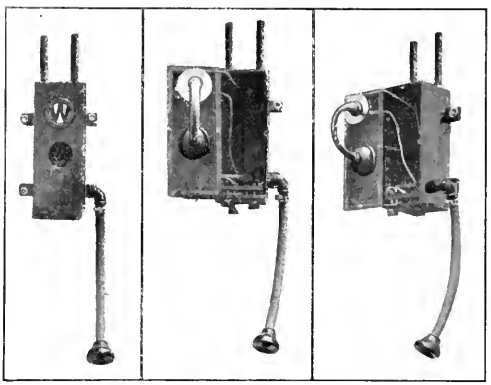
Development work consisted of 1971 ft. of drifts, 2411 ft. of crosscuts, 1226 ft. of raises, 532 ft. of box-holes, 83 ft. of shaft—total, 6223 ft. In addition to this work diamond drilling amounted to 5875 ft., and enlarging and straightening drives, station construction, and sumps, 85,000 cu.ft. The development work was distributed on the various levels within a zone of 1500 ft. long by 400 ft. wide. Ore reserves are estimated to contain 2,782,811 tons of ore, having an average value of $4.15 per ton.

The mill is expected to reach its maximum capacity of 28,000 tons per month during the coming year. During the year under review, operating 342 days, or 93.7% of the total possible time, it treated 248,550 tons of ore. The average value of the ore sent to the mill was $4.68, of which $2.70, or 57.6%, was saved by amalgamation and $1.54, or 33%, was saved by cyanidation. The total mill extraction was 90.6%. An increase in amalgamating plate area is in process of erection, as a greater extraction by amalgamation is expected.

The small 16-cu.ft. cars used for tramming and hauling ore on the main level and up the incline shaft to the crusher have been replaced by 93-cu.ft. cars. The cost of crushing and conveying has been reduced from 25.2c. to 12.6c. per ton. A system is being installed consisting of 5-ton cars for underground use, a large underground crusher, automatic loading hoppers, 4-ton skips, and a surface haulage with 5-ton cars to the crusher from the No. 2 shaft. The operating costs, based on a total cost of $737,551, were as follows per ton of ore milled: Mining, including hoisting, 68.2c. per ton; development, 69.7c.; crushing and conveying, 12.6c.; reduction, 99c.; general, 46.1c.—total, $2.967 per ton milled. The company ended the year with $484,040 in current assets and $43,011 in current liabilities. An issue of 50,000 shares of treasury stock is contemplated to furnish funds to carry on development to determine as quickly as possible the tonnage of ore that may be profitably mined.

Weiss Mine Telephone

A new mine telephone has recently been developed and is being placed on the market by L. T. Weiss, of New York City. The troubles in the generally accepted mine telephone are due to rapid battery deterioration, grounding of the battery, breaking of parts because of extremely rough handling, corrosion of small wires, corrosion of transmitter diaphragm, breaking down of induction



THE WEISS MINE TELEPHONE

coils, etc. A central-energy system, phone and the present circuit were worked out. The central relay and battery are located in a suitable place on the surface. The whole system can be quickly installed on the old wiring without change.

The phone itself consists to outward appearance of an iron box with an opening to speak into, an armored rubber hose for listening purposes and the two buttons. No cord, wiring, or mechanism are visible. The transmitter, receiver and wiring are permanently locked up. The transmitter is connected to the speaking opening by a connection also in the box, which prevents any moisture, expectoration, or mechanical injury reaching the diaphragm. The only damage that can be done is by the removal of the armored rubber listening tube. Even this would not put the phone out of service and anyone could readily slip the hose or another one in place, or could listen at the hole over which the tube was placed.

This phone has been in operation in several mines for over a year. It is claimed by its maker to be absolutely foolproof and able to meet any possible condition.

PERSONALS

Fred C. Alsdorf has been in New York for the past few weeks but expects to return West soon.

J. V. N. Dorr will spend most of the month of July in Colorado. During August he will be in San Francisco.

Dr. F. W. McNair, president of the Michigan School of Mines, is visiting the mining centers of northern Ontario.

W. B. Bretherton has resigned his position as head chemist at the Dome Mines, Porcupine, Ont., and has gone West.

A. A. Hassan has been appointed consulting engineer for the Crimora Manganese Corporation, operating at Crimora, Virginia.

G. C. Bateman, of the Canadian Mining & Exploration Co., recently examined the Beaver Lake and Herb Lake districts, in Manitoba.

Irving A. Palmer has been appointed superintendent of the Altoona zinc-smelting plant (Altoona, Kan.) of the United States Smelting, Refining & Mining Co.

John D. Ryan left New York on July 2 for Michigan, after which he will visit Montana and the Pacific Coast, not expecting to return until late in the summer.

W. H. Glasgow has been made assistant general superintendent of the H. C. Frick Coke Co., with headquarters at Scottdale, Penn. Clay F. Lynch is general superintendent.

Robert E. Harris, president of the Nova Scotia Steel & Coal Co., Ltd., has been appointed a judge of the Supreme Court of Nova Scotia, which will necessitate the election of a new president.

Archibald Jones, formerly general manager of the Bartlesville Zinc Co., at Bartlesville, Okla., has been appointed general manager of the American Zinc & Chemical Co. of Langeloth, Penn., succeeding N. L. Heinz.

Joseph Cooper was appointed assistant superintendent of the Farrell openhearth steel works of the Carnegie Steel Co., succeeding Norman S. Powell, who has been appointed superintendent of the North Sharon openhearth works.

W. S. Greenawalt, assistant superintendent of the openhearth department of the Pennsylvania Steel Co., has been appointed superintendent of the openhearth plant of the American Iron & Steel Manufacturing Co., Lebanon, Penn.

F. E. Parks has been appointed manager of the Minnequa works of the Colorado Fuel & Iron Co., succeeding J. B. McKennan, whose appointment as general manager of the company, with headquarters at Pueblo, Colo., was recently announced by President Welborn.

L. Jorgensen has resigned from the firm of F. G. Baum & Co., San Francisco, and will engage in general electric- and hydraulic-engineering practice, specializing in the design of arch dams. His office is 1404 Chronicle Building, San Francisco. Mr. Jorgensen is inventor and patentee of the constant-angle multiple-radius dam.

Robert I. Kerr, for many years bookkeeper at the Kennedy mine, has been elected to the position of secretary of the California Metal Producers' Association at San Francisco. He succeeds John Mocine who resigned to accept the position of superintendent of the Pittsburgh Silver Peak mine in Nevada. Mr. Mocine was formerly a resident of Nevada. Mr. Kerr is a member of the California legislature for Amador County and was chairman of important committees which rendered good services to the miners during the last session of the legislature.

OBITUARY

James H. Goudie died at Newberry, Mich., June 24, aged 67 years. He was born in Scotland, but had been in Michigan for 30 years, during most of which time he had been engineer of the Metropolitan Iron & Lead Co., with headquarters at Ironwood.

R. C. Scott, secretary and treasurer of the Morris Machine Works, Baldwinsville, N. Y., died suddenly July 4, while playing golf on the links of the Onondaga Club. He was 66 years old and was well known as a manufacturer of mining, pumping and general machinery for many years.

Robert Patterson Andrews died at Denver, Colo., June 24, aged 73 years. He was born in Pennsylvania and graduated from Lafayette College at Easton. He went to Colorado in 1863 and worked as an assayer at Aspen, Creede and other camps. For 30 years past he had been assistant assayer and melter at the Denver Mint.

Ernest Porter, receiver for the New York State Steel Co., Buffalo, and former superintendent of the steel plant of the Carnegie Steel Co. at North Sharon, Penn., died at his home in New Wilmington, Penn., June 16, aged 42 years. He was graduated from Westminster College and was first employed as a chemist at the North Sharon works, rising to become superintendent of the plant. He was also for a time in charge of the openhearth furnace department of the Tennessee Coal, Iron & Railroad Co., Birmingham, Ala. He leaves his widow and four sons.

SOCIETIES

American Institute of Mining Engineers—The next meeting of the Utah section will take place on July 15 and will take the form of an excursion to the Tintic district leaving Salt Lake City on the morning of that day and returning on July 16. Arrangements have been made for special cars for the members and facilities will be provided for visiting the different mines in the district. While at Eureka, the members will be guests of the district. A session will be held there, at which two papers will be presented; one by G. W. Crane on "Geology of Ore Deposits and Geological Methods Applied to Mining in the Tintic District;" and the other by D. A. Lyon on "The Zinc Problem in the Treatment of Low-grade Zinc and Zinc-Lead Ores."

American Society for Testing Materials—The 18th annual meeting of this society was held at Atlantic City, N. J., June 22 to 25, with a large attendance. The meeting was a busy one, no less than 55 committee reports, papers and addresses being on the program. Among the committee reports were those on standards for high-carbon steel, splice bars and track bolts; boiler tubes; welded steel and wrought-iron pipe; chemical analysis for alloy steels; chains; methods of sampling and analysis of pig iron; bars for springs and many other important topics. The report of the executive committee recommended an increase in dues for the purpose of meeting the increased expenses for publications incurred by the association. A number of the committee reports were debated and referred to letter ballot by the association. Announcement was made that owing to the European war, the congress of the International Association which was to have been held at Petrograd, Russia, in August, has been indefinitely postponed.

INDUSTRIAL NEWS

The Waterbury Co., manufacturer of manila, sisal and wire rope, on July 1 removed its general offices from 80 South St. to 63 Park Row, New York City.

The National Slag Co. announces the removal on July 1 of its offices from 30 Church St., New York, to the Kinney Building, Broad and Market St., Newark, N. J.

William Jacks & Co., of 5 East India Ave., London, and 111 New St., Birmingham, states that it is not connected with the Glasgow firm of the same name which has been prosecuted in Edinburgh by the British Government under the "Trading with the Enemy Acts"; that no member of the London firm has any interest in such Glasgow firm, and that no member of such Glasgow firm has any interest in the London firm.

The litigation that has been carried on for the last several years between the Marion Steam Shovel Co. and the Marion-Osgood Co., has been amicably adjusted. This settlement covers all machinery heretofore shipped by the Marion-Osgood Co. and grants to it shop rights to continue the use of those patents held by the Marion Steam Shovel Co., which are involved in the Marion-Osgood Co. machines as at present constructed.

On June 1 the Ingersoll-Rand Co. opened a branch office in San Francisco, Calif., at 139 Townsend St. with a view to giving closer attention to users of Ingersoll-Rand machinery than it is possible for any agency to do. Harron, Rickard & McCone will still coöperate in the sale of Ingersoll-Rand machinery after the expiration of its agency contract on July 22 next. H. L. Terwilliger is district manager for the territory handled by the San Francisco and Los Angeles offices, with headquarters in San Francisco.

Editorial Correspondence

SAN FRANCISCO—June 30

The Field Process Co. is reported to have complied with the requirements of the California "Blue Sky" commission and has been authorized to dispose of sufficient stock to build a new plant at Redding. This is evidently the same process that was installed at Redding more than a year ago and which attracted chiefly the interest of farmers. Whatever improvements may have been made, there is no record of practical commercial demonstration of the process. The first plant was built with money furnished by farmers who were fighting the smelters and the probability is that the stock for the present undertaking will be disposed of to the same men.

Guggenheim Interests on Yuba River complain that old-fashioned miners with pans and rockers have been encroaching upon the Guggenheim dredging ground between Marysville and Smartsville. The May rains and consequent high water in the streams offered a temptation which the old-type placer miners, who have been on the job for the past 50 years, could not very well resist. The Guggenheims have sent the sheriff after them, but it is understood the 20 or 30 miners have cleaned up enough to satisfy their present wants or grubstake them for prospecting trips in regions not controlled by the big interests. When the camp was being installed on American River for the construction of Natomas No. 10, the first all-steel dredge operated in California, an old prospector and miner who knew the ground better than the Natomas people did, was cleaning up big pay in a long tom. He was asked by the manager if he knew whose land he was on. He replied in the affirmative and abandoned his digging. He was told to return and get what he could off the surface until the dredge got in operation, but this extraordinary offer of the manager caused him to be suspicious that some sort of trap was being laid for him. In many placer districts in California the value of the ground for dredging has been brought to the attention of dredging companies by the operation of these old timers and usually large companies would rather encourage than drive these prospectors away.

Semi-monthly Pay Day provided by Assembly bill 487 has become a law in California. Under its provisions all wages or compensation in private employments shall be due and payable at least semi-monthly. The act does not prevent payment more frequently than twice a month. Every employer is required to establish regular pay days and maintain notices of such pay days. All wages earned and unpaid prior to the first day of any month shall be due and payable not later than the 15th day of the month following the one in which the wages were earned and all wages unpaid prior to the 16th day of any month shall be due and payable not later than the last day of the same month. Employees are safeguarded against practice of some employers of paying in non-negotiable paper by the provision that payment of wages shall be in lawful money of the United States or by a good and valid negotiable check or draft payable on presentation at some bank or established place of business situated in the state. Such payments are without discount. If an employee is absent on the regular pay day he shall be paid within five days after making demand. Violations of the law are misdemeanors and the Bureau of Labor Statistics has power to enforce the law. Some of the mining companies have complained that the enforcement of this law will retard mining and work a hardship upon those mines which are in the habit of cleaning up once a month. The talk that a semi-monthly pay day will put some of the mines out of business is not considered seriously. There may be a few mines in the state which would suffer some inconvenience and possibly temporary hardship. But the California mine that is unable to pay wages twice a month would not last very long anyway. One trouble with California mine operators is that they have been subjected to so few legislative regulations that anything in the way of mining law is considered a hardship. So far the only legislation that has done any injury to mine operators is the insurance clause of the Workmen's Compensation law. That has been softened by the action of the Metal Producers' Association.

BUTTE—July 1

Compensation Law—The Anaconda Copper Mining Co. posted notices at all of its Butte mines, at the Washoe plant at Anaconda and at the Great Falls plants that it had adopted the No. 1 plan of the new compensation law which went into effect July 1. Under this plan the company carries its own insurance. If an employee meets with an accident settlement is made direct by the company with the injured employee or in the event of his death with his heirs. Settlement is made under the schedule provided in the new law, referred to in the "Journal" of June 19. Beside the Anaconda company, the North Butte and the Butte-Alex Scott also posted notices to the effect that they had adopted plan No. 1 of the new law. The Butte & Superior, East Butte, Butte-Ballaklava, Davis Daly, Butte Zenith and many of the smaller companies posted notices that they would elect plan No. 2 of the new act. Under this plan the companies insure against accidents with guarantee companies approved by the state industrial accident board, which has charge of the enforcement of the compensation law. In case of accident the insurance companies settle with the injured, or with the heirs in case of death. Most of the mining companies of Montana, outside of Butte have adopted plan No. 2. The Anaconda company also posted the following notice from the Industrial Accident Board:

Notice to employees:

In accordance with the provisions of the workmen's compensation act, chapter 96, Session Laws 1915, this is to advise you that unless you serve written notice on your employer, and file a copy with the industrial accident board, Helena, Montana, of your election not to come under the law, that the act as adopted by your employer, will immediately apply to you.

If you do notify your employer and the above named board that you elect not to come under the said act, you may afterwards revoke such claim by a notice in writing, served on your employer and a copy filed with the above-named board, which notice shall take effect on the first day of the next succeeding month, after which time the law as adopted by your employer will apply to you.

Injury Not Resulting in Death—Notice of—An employee who has been injured in the course of his employment and whose incapacity extends over a period of two weeks shall serve written notice of such injury on his employer (from whom blank forms may be obtained) a copy of which report must be sent to the Industrial Accident Board, Helena, Montana, and which notice shall be signed by the person injured, or someone in his behalf, and shall state in ordinary language the time, place and cause of the injury.

Injury Resulting in Death—Notice of—When death results from an injury received by an employee in the course of his employment, notice shall be served by his beneficiary or dependants, or someone in their behalf.

Limit of Period of Notification—Notice of injury, not resulting in death, must be given to the employer within 60 days after the happening thereof, and claim for compensation for personal injury or death shall be made within six months, or in the event of an injured workman who is mentally incompetent and without a guardian, or an injured minor under 16 years of age who may be without a parent or guardian, a guardian in either case may be appointed by any court of competent jurisdiction and notice shall be given within six months after the appointment of the guardian or when such minor arrives at the age of 16 years. No proceeding for compensation under this act shall be maintained unless these rules are observed.

Each of the employees of the mining companies was presented with a copy of the hospital agreement under which they agree to pay $1 per month for hospital fees. This includes a waiver of the provisions of Section 16-F of the compensation act.

SALT LAKE CITY—July 2

The Utah Copper Co.'s Production in May was 14,063,765 lb. of copper, compared with approximately 13,000,000 in April. Ore production has been increased, and according to reports in Bingham, as high as 28,000 tons of ore a day have been handled. The Bingham & Garfield R.R. has run 9 or 10 ore trains of about 40 cars each a day, which would mean from 17,000 to 20,000 tons of ore, the remainder being carried by the Denver & Rio Grande, which handles 7500 tons daily under contract, and at present is carrying 1500 tons extra, or about 9000 tons all told. In March, the Utah Copper raised its quarterly dividend rate from 75c. to $1 per share. The company began paying dividends in December, 1908, with 50c. quarterly, and has not missed a payment since that time, being the only one of the important copper producers to maintain its rate following the outbreak of the European war. On June 30 the company paid $1,624,489.

A Better Mining Year for Utah in 1915 than had been anticipated, which will compare with, or equal, the record year of 1913, is predicted by the U. S. Geological Survey, based on reports from its Salt Lake office. The survey states that the outlook in Utah is bright, though mining was dull after the beginning

of the European war, and did not improve until March, when increased demand for metals caused the mills and smelteries to increase capacity. Following higher metal prices, the immense stockpiles of ore at one or two of the smelting plants in Utah are being rapidly worked up for their lead and copper, and only producers of carbonate or siliceous ores have preference or find a ready market. In some cases, as in the purchase of zinc ores, buyers have been powerless to take more and refuse to consider ore which has not previously been arranged for by contract. Lead producers during a few days of extremely high prices found smelters refusing to make contracts except on previously prevailing prices, with only half of the new quotation added. Producers with contracts for the sale of lead ore increased their shipments slightly, and enjoyed the high prices.

The Ohio Copper at Bingham, which is being operated under lease by the General Exploration Co. has two sections, Nos. 1 and 3, of the mill in operation treating 1900 to 2000 tons of ore daily. The third section will be started in a few days, and will increase the capacity to 2500 tons. When the company was operating, up to 3000 tons per day was treated. Operations by the leasing company have not yet been brought up to capacity, partly on account of some repairs made to the compressor machinery. A caving system is being used, and the mining costs have been placed at 25c. a ton. Since December, 1909, the Ohio Copper Co. has mined 3,058,000 tons of ore by caving. The orebody consists of crushed quartzite impregnated with pyrite, chalcopyrite and chalcocite, also a notable amount of cuprite in places. It occurs between two fissures, several hundred feet apart, and extends from the 100 level down to the 1300 or Mascotte tunnel level. The ore is mined in 100-ft. blocks, and delivered by three main chutes to bins on the Mascotte tunnel level, from where it goes direct to the mill. The ore is concentrated about 30:1, and the concentrates are shipped to the A. S. & R. at Garfield. At present between 200 and 300 men are employed.

FAIRBANKS, ALASKA—May 31

The Rate on Ore to be transported from Fairbanks to either Seattle or Tacoma is quoted as follows by the American-Yukon Navigation Co.:

Ore Sacked	Rate per Ton
1 to 5 tons	$25.00
5 to 20 tons	22.50
20 to 50 tons	20.00
50 to 100 tons	17.50
100 to 250 tons	15.00
Over 250 tons	Special

The ore will be routed via St. Michael in connection with either the Alaska Steamship Co. or the Pacific Coast Steamship Co. This "Special Development Rate" now in effect, will, unless revoked before that time, be effective until the close of navigation in 1915.

SEATTLE—June 28

A Report on Tolovana, the first authentic summary of the prospects for the new district are contained in a report given out by Delegate Wickersham, of Alaska, who has just completed a thorough investigation of the district. He reports that the latest strike continues to draw the interest of miners in the North and at the present time there are about 300 in camp, busy prospecting and doing development work on already proven ground. Enough pay has been found to establish at least a small camp and there is every indication that it will be a larger one. More work has been done in opening the new district in the last six months than was done in the entire Fairbanks district during the first two years. Some gold is being rocked out in small quantities, but no sluicing has yet been done although an outfit on Olive Creek expects to start shortly and the first cleanup will be reported about Aug. 1 which will show what has been located on that particular creek. On Livengood Creek a line of pay has been opened extending some two miles. Along the line of the different holes sunk, pay averaging between $1.25 and $1.50 has been found on bedrock on the right limit bench and fourth tier. Lower down along the creek another line of pay has been opened showing about dollar dirt; however, it lies 30 ft. to bedrock, while the bench pay runs between 90 and 100 ft. The diggings are deep, not shallow as was at first supposed, and necessarily the prospecting is slower and more costly. In both the Shushanna and Nelchina camps it was only a few feet to bedrock, which explains their rapid development, once pay was found. In the Tolovana district it is necessary to have hoists, boilers, cables, buckets and equipment which is heavy to transport and at present the transportation facilities are poor. The summer trail from Fairbanks is impossible for heavy wagons and is being used now only by packers. The Alaska Road Commission is now investigating routes with a view of constructing a summer highway. Water transportation is the only solution this summer and small steamers and power launches go up the Tolovana 150 miles to what is called the Big Jam, extending over three miles which is impassable. There is a 2100-ft. tram being built across the portage, effecting a saving of about 30 miles whence small boats travel to within about 6 miles of the diggings on Livengood Creek and most of the freight is going this way. The Fairbanks Telephone Co. is now stringing wires to the new camp from Fairbanks. Possibly the best bunch of experienced mining men and prospectors that ever went into a new Alaskan district are opening up the Tolovana and it only needs the news that good cleanups are made when the sluices are working, to start one of the biggest stampedes the North has ever seen.

WALLACE—JUNE 30

The Sale of the Success Mine is the most important deal consumated in Wallace in many months. On June 24, H. F. Samuels sold his holdings of 1,100,00 shares of Success Mining Co. stock for $1 per share. The total outstanding stock is 1,500,000 shares. The purchasers are said to be Duluth people, the same who acquired control of the Reindeer-Queen property at Mullan. The Success mine is located on Nine Mile Creek, about one and one-half miles from the Interstate-Callahan property and is one of the oldest locations in the Coeur d'Alenes. It was first operated by the Granite Mining Co. and under that control produced $600,000 in lead and silver. As depth was obtained the ore became richer in zinc but at that time there was no market for zinc ore mined in the Coeur d'Alenes. Mr. Samuels obtained control in 1905 and formed the Success Mining Co. A large amount of development disclosed a large tonnage of high-grade zinc ore containing enough lead to pay the operating costs. A 200-ton mill was constructed which has proved successful in separating the lead and zinc at a ratio of concentration of 2:1. Dividends were suspended Apr. 20, 1913, up to which time $345,000 had been paid. Dividends were resumed Apr. 20, 1915, and since that time three dividends, 17 cents in all, amounting to $105,000, have been paid. During the month of June the mine is said to have earned 8 cents per share. The company has an excellent smelting contract which runs until May, 1916.

DULUTH—July 3

Ore Shipments for June via Duluth-Superior docks were as follows:

	June, 1915	June, 1914
Duluth & Iron Range	1,224,026	1,075,193
D. M. & N.	2,146,501	1,045,734
N. P.	2,043	19,472
Soo Line	122,408	50,659
Great Northern	802,085	1,944,606
	4,357,063	4,135,664

Total 1915 shipments to July 1 aggregate 8,892,792 tons, as against 5,817,791 tons for 1914.

JOPLIN—June 30

Our Early and Repeated Warnings regarding wildcat zinc mining investment that would follow an era of high ore prices have already been justified. Every old worked-out mine and abandoned prospect in this district is being rigged up to sell, but while a number of investors are coming in they are not throwing their money away as they did 15 years ago.

A General Strike Was Called on June 28 by the zinc miners in the Joplin district and 2000 or 3000 marched about the district calling on all the other miners to quit work and join them. The demand is for more wages. Wage increases were granted recently when zinc ore reached such a high price, and when prices dropped, some of the operators reduced wages, but none are said to have been cut to what they formerly were. Several of the large producers have shut down for two weeks and they assert they will remain closed indefinitely rather than deal with Moyer and the Western Federation who have a hand in the strike in another effort to get a formidable foothold in the Missouri fields.

TORONTO—June 28

As a Result of Outrages in Canada by alien enemies, there is a strong feeling in Northern Ontario in favor of interning the Germans and Austrians, at present employed in large numbers in the mining districts. Petitions to the government to that effect, circulated principally in Cobalt, Haileybury and New Liskeard, have obtained about 1000 signatures, and have been endorsed by the Cobalt Board of Trade. The presence of so many men of enemy nationality in the mining camps is regarded as especially dangerous owing to the large quantity of explosives which are accessible, and the fact that many of the foreigners are accustomed to their use. The petitions will be presented to Gen. Sam. Hughes, Minister of Militia.

The Mining News

ARIZONA

Gila County

INSPIRATION (Miami)—First section of Inspiration mill started up June 29.

Maricopa County

SUNFLOWER CINNABAR (Phoenix)—Preparing to resume operations at property 65 miles northeast of Phoenix. Company plans to build wet-process plant. At present 3-ton retort is being used for extracting quicksilver.

Mohave County

OATMAN GOLD M. & M. (Oatman)—Installing machinery at main shaft; will sink 500 ft.

UNION BASIN (Golconda)—Has just commenced operating new 30-ton oil-flotation plant, and as work progresses expects to erect zinc-tailings regrinding plans and add further flotation equipment.

Yavapai County

ROSALIE COPPER (Mayer)—Preparing to resume work on property 18 miles east of Mayer. George C. Meese, of Los Angeles, is president.

BIG LEDGE DEVELOPMENT (Humboldt)—Has more than 40 claims three miles east of Humboldt on which diamond drilling is proving up orebody said to average 7% copper.

CALIFORNIA

Amador County

SOUTH EUREKA (Sutter Creek)—Orebody on the 2000-ft. level has widened out and developed some high-grade ore.

MOUNTAIN KING (Pine Grove)—Robinson Co. recently obtained new bond and option and is prosecuting development work. Large amount of ore extracted but mine will be deepened before treatment is undertaken.

Butte County

NUGGET GRAVEL (Lovelock)—Reported that Smith Bros. encountered rich gravel, taking out $400 in one week. One nugget was worth $180. Property is situated on upper end of old Indian Springs mine.

BERRY CREEK DISTRICT—Mining camp near Oroville on Western Pacific R.R. is credited with recent strikes of good ore. M. A. Chapan is hauling in machinery for development. Charles Nelson has opened up gravel claim in same district.

Calaveras County

ROYAL GOLD (Hodson)—Dropping 40 stamps; preparing to add 10 more immediately, to be followed by 10 more, making 60-stamp mill with 300-ton capacity.

Fresno County

HIGHWAY COMMISSIONERS have been appointed by Board of Supervisors. An engineer will be selected and it is proposed to bond county for $3,000,000 for good roads. Coalinga oil district is in this county and will receive a large share of the benefit from road construction.

Inyo County

REWARD GOLD (Russ Mining District)—Property located east of Mt. Whitney is preparing to install cyanide plant. Thomas & Rudderow, of San Francisco, is financing the company.

Kern County

ATOLIA (Atolia)—High-grade ore is being extracted from 900 level of Churchill group. Reported that company has large contracts for tungsten.

KING SOLOMON (Randsburg)—Cleanup of 110 tons at Red Dog mill returned $6100, an average of $54.50 per ton. The largest part of ore came from 300 level.

CONSOLIDATED (Randsburg)—Water encountered in shaft in January has increased sufficiently to provide almost enough to supply 5-stamp mill which is running three shifts. About two years ago water was encountered by this company in Wedge shaft. Early in period in which this first water was pumped, there were many conjectures as to source, and doubts were freely expressed that water would be permanent. Company is now selling water from Wedge shaft to neighboring mines which formerly had water hauled in in railroad tank cars.

YELLOW ASTER (Randsburg)—Superior Court of Los Angeles denied petition of Mrs. Stella de Pauw for removal of Ward Chapman from position of coëxecutor of estate of John Singleton, Mrs. de Pauw's former husband and one of discoverers of Yellow Astor mine. Reported that Mrs. de Pauw has gone to San Francisco to take matter up with A. Van Coenen Torchiana, consul general of the Netherlands. Mrs. de Pauw by her second marriage has become a citizen of Holland and evidently is of opinion that American courts have no jurisdiction over her affairs except the decision be in her favor.

Nevada County

ERIE (Graniteville)—Number of leasers started work under supervision of Fred Weiss, agent for owning company.

GOLDEN CENTER (Grass Valley)—Collar of new incline shaft has been timbered and connections are being made with old workings. Sinking will be resumed and shaft deepened to 1000 ft.

ERIE (Graniteville)—Property will be worked by leasers under management of Thomas Haddy of Virginia City, Nev. J. W. Swearingen will have charge of mill. Property is owned by West Virginia men.

CASSIDY (Grass Valley)—Unwatering shaft is progressing. New electric pumps have been substituted for air pumps and sinking will begin as soon as water is out. Twenty men are employed. George St. John is manager

Placer County

FEDERAL DRIFT (Dutch Flat)—Recent find of ore reported in crosscut tunnel connected with old Rough and Ready works indicates that Dutch Flat may again be placed on mining map of California. Camp was producer in days of early placer mining.

CALIFORNIA-HAWAIIAN DEVELOPMENT (Auburn)—Reported that property on Ralston divide in Long Cañon district will be reopened and that tunnel from south side of ridge will be driven in hope of tapping channel which tunnel on north side failed to reach. Property is situated in northern portion of Eldorado National forest.

San Luis Obispo County

CAMBRIA (Cambria)—More than one-half mile of tunnel, started last fall, has been completed. A bucket tramway will be installed for carrying ore from the mine to the furnaces.

Shasta County

INDEPENDENT AND EXCELSIOR (Arbuckle)—A suit has been brought by Frank A. Greene and others against John H. Purcell and others to clear title to these claims and Daisy No. 1, 2 and 3.

ANCIENT-RIVER prospecting near Redding is in progress. The drift is in 30 ft., disclosing blue gravel. A 50-ft. chute connects with string of sluice boxes bringing water from Whitlaw Creek. Mr. Nelson is manager.

NOBLE ELECTRIC STEEL CO. (Heroult)—Reported that preparations are being made for running electric smeltery to its full capacity. One furnace has recently been in operation and produced 25 tons of steel. Manganese ore is being shipped to smeltery from Mendocino County. Ore is mined about 5 miles from Redwood Valley. Preparations were being made in middle of May for shipment of one car load per day. Hoist tramway and ore bins have been installed and 20 men are employed.

Siskiyou County

GEORGE MILNE (Scott Bar)—G. A. Milne has completed his cleanup of one month's hydraulic mining which returned $1950, all specimen gold. Smallest pieces average little more than one dollar each, and largest $438.

NORTHERN (Callahan)—Company composed of San Francisco men has taken over placer ground of Grouse Creek Mining Co. at confluence of east fork of Scott River and Grouse Creek. Edward C. Latchem is manager. Property will be worked by hydraulic methods.

SPENCER (Yreka)—T. W. Kirk, of Humbug, made recent cleanup of 73 tons of ore from old dump which had been put through an arrastre. Return was $408 or more than $55 per ton. There are several thousand tons of dump ore at mine which will probably run an average of near this value. Recent cleanup was from samples taken from various parts of the dump. Spencer is one of oldest operated mines on Humbug Creek. There are number of old mines in this region that were former producers which have large amounts of ore on dump that would pay well under modern treatment.

Tuolumne County

NYMAN CONSOLIDATED (Jamestown)—Ore is being extracted from Knox and Boyle vein on 300, 400, and 600 levels. Extensive development is planned in Nyman claims, where good ore was formerly found. Ten of 40 stamps are dropping and mill will gradually be worked up to capacity. This property is commonly known as Santa Ysabel.

Yolo County

PLACER GOLD is reported to have been discovered in Casey Flat west of Amaranth. Yolo County has no record of gold production nor of any other metals. There have been traces of oil and gas.

COLORADO

Boulder County

WHITE RAVEN (Ward)—Contract has been let to sink shaft 100 ft. to 340 level. Contemplates sinking shaft to depth of 500 ft.

ALICE (Jamestown)—This mine produced principally lead-silver ore in earlier operations but now shows shoot of gold-telluride ore 5 ft. thick.

HUMBOLDT (Ward)—Hallett and others are building mill which will run both for custom ores and for treatment of product from this mine.

HOODOO (Gold Hill)—Mutual Coöperative Mining Co., of which Frank E. Wire is secretary, will reopen and operate this old group, including Columbus mine.

TROJAN MINING & ORE REDUCTION CO. (Ward)—This is new company formed to take over and develop New Market properties. Shaft is 500 ft. deep and vein is now developed by five levels from 200 to 500 ft. in length. New company contemplates remodeling of mill and installation of addi-

tional equipment. It is considered probable that some heavy sulphide ore developed can be satisfactorily smelted and installation of hot-blast pyritic smelter is under consideration.

Clear Creek County

KANSAS LEASING (Idaho Springs)—Company is developing Kansas vein through Newhouse Tunnel. Vein 30 in. wide has been opened assaying $12 to $14 per ton.

IDAHO BRIDE (Idaho Springs)—New compressor plant being installed. Extensive drifting and sinking are planned. Idaho tunnel will be pushed to intersect several strong veins. Mill is running two shifts.

ENGINEERS' LEASING (Idaho Springs)—Winze sunk to 110 ft. below tunnel level on Dyke vein. Drift east 100 ft. and raise from this drift has opened 15-in. vein of $60 ore. Large flow of water is under control.

SYNDICATE (Dumont)—New machinery for 50-ton milling plant has arrived and will be installed in old Kaverne mill building. Will treat ore from Syndicate and other properties in district.

BIG FIVE (Idaho Springs)—On account of increase in number of operators in Big Five tunnel, company has found it advisable to install additional air compressor operated by electricity. Will have capacity of 1700 cu.ft. of free air per minute. W. P. Daniels is president and general manager.

LAKE (Idaho Springs)—Tunnel No. 2 is now in 1200 ft. from portal. Concentrating ore is being opened in this tunnel and in Tunnel No. 4, which is driven at higher level. Electric drills and ventilating equipment will soon be installed. Property is being developed by Quigley & Co.

JOSEPHINE (Georgetown)—Mendota Leasing Co. has secured lease on this property and has commenced construction of 25-ton mill to treat ore from dumps and old stopes. Machinery for plant has been purchased and mill will be in working order within next 30 days.

Dolores County

PRO PATRIA (Rico)—Shelhamer and Batchlor, who opened small but rich shoot last March, have made second strike of similar ore in Jumbo No. 2 vein that has heretofore been considered worthless.

Gilpin County

KANSAS (Central City)—This mine is being operated through Argo tunnel with portal at Idaho Springs. Leasers have opened strong shoot of $12 ore and are making good shipments.

Lake County

DERRY RANCH GOLD DREDGING (Snowden)—Construction of dredge proceeding rapidly under superintendence of Robert Gore, formerly superintendent of Rovett boat at Breckenridge now owned by the Tompah Placers Co. New dredging site is about 12 miles southwest of Leadville along the Arkansas River. Dredge will have 5½-cu.ft. buckets. Colorado Power Co. is erecting 6½-mile transmission line. R. F. Lafferty is general manager.

San Juan County

SILVER LAKE (Silverton)—Mill has started as custom flotation plant. First mill run was made on ore from Big Giant property.

GOLDEN MONARCH (Gladstone)—Development will be commenced on this property which lies south of Gold King mine. Work will be under the direction of J. M. Kloster.

BROAD GAUGE (Silverton)—J. M. Laqueer and associates, of Pueblo, have secured an option on this property in Burns Gulch and will start development work in near future.

HAMLET M & M (Silverton)—Mine and mill have been placed in working order and operations have been resumed. E. A. Ritter, of Colorado Springs, is consulting engineer.

BANDORA (Silverton)—Operations will be resumed at property in South Mineral Creek in near future. Company contemplates development work on Bandora, Little Todd and Cataract veins.

San Miguel County

HUMBOLDT MINES (Telluride)—New organization formed by Bulkeley Wells and associates to take over Humboldt, Sailor's Fortune and Tom Payne properties together with all property of Old Dominion Mines Corporation. Property will be developed and operated through adit level of old Sheridan mine. Ore is similar to that of Smuggler-Union and will be transported over Smuggler system of tramways to Pandora mill for treatment. Work of extending power lines for operation of electrical equipment at Humboldt properties under way. Men have been put to work on development and management hopes to have mines in condition to produce 150 tons per day within about five months. Bulkeley Wells is general manager and C. N. Bell will be superintendent.

Teller County

SITTING BULL (Victor)—Main shaft has been sunk to 400 ft. and levels are being driven.

TRAIL (Goldfield)—Shoot recently opened on 1200 level has been developed 100 ft. by drift and shows 1-oz. ore 5 to 10 ft. wide.

KOYHNEO (Victor)—Claim is within city limits. Promising discovery made on 200 level almost beneath high-school building.

LAST DOLLAR (Victor)—Gibbons lease, 1200 level, after long deadwork, has 5-ft. shoot of $14 ore. Company pushing development on 900 level.

IDAHO

Shoshone County

HECLA (Burke)—New addition to Hecla mill is now running on full time and full capacity. Mine production is about 16,000 tons per month.

TERRIBLE EDITH (Murray)—Has begun shipment of zinc ore to Eastern smelters. Ore shoot has widened to 8 ft. and stope is now 70 ft. long. Charles Conn is manager.

HYPOTHEEK (Kingston)—Shaft is now down 1085 ft. and will be sunk 100 ft. deeper before crosscutting, making next level 300 ft. below 900 level. Down to that point levels have been opened at intervals of 200 ft. Work at mine is limited to shaft sinking until final depth is reached.

HERCULES (Burke)—Mine and mill still idle and no new developments regarding smelting contract situation. Rumor has it that St. Regis and Superior, towns in Mineral County, are both under consideration for location of smelting plant. Location would serve mines at Wallace, Saltese, and the Iron Mountain and Amador districts. Osburn is also candidate.

MICHIGAN

Copper

MICHIGAN COPPER (Rockland)—After an idleness of five or six years will resume exploratory work. An assessment has been levied and largest creditors have consented to withhold their claims, pending results of development. Butler shaft, sunk many years ago to depth of 300 ft. will be deepened to 700 ft.

Iron

OLIVER (Ironwood)—All of Oliver mines at Ironwood are now working six days a week. For almost a year past they had worked but four days out of every six. Oliver is shipping strong from Gogebic Range. Shipments are already far ahead of 1914 for same months. Next to Oliver heaviest shipper is Oglebay, Norton Co.

MINNESOTA

Cuyuna Range

INLAND STEEL (Crosby)—Experimental concentrator now washing 500 to 600 tons daily, having been in operation for several days.

BUFFALO & SUSQUEHANNA (Hibbing)—D. M. & N. Ry. is now hauling output from this mine instead of Great Northern as formerly, 6000 tons daily going forward.

CUYUNA-SULTANA (Ironton)—Contrary to press reports widely circulated, U. S. Steel Corporation has made no attempt to secure control of this property and has no interests on Cuyuna Range and displays no interest in acquisition of any property here.

BRAINERD (Barrows)—Capitalization increased from $25,000 to $125,000. Company owns fee to Barrows Mine, formerly operated by M. A. Hanna & Co. Recent drilling on property has greatly increased tonnage and improved grade of ore. No announcement made as to reason for increase of capitalization.

BRAINERD-CUYUNA (Brainerd)—Following unique custom of Cuyuna Range stock companies, this company conducted excursion to its property for benefit of its Duluth stockholders, 120 miles distant, on July 4. At that time mine hoisted its first ore, although no considerable tonnage will be hoisted for several months.

Mesabi Range

MISSABE MOUNTAIN (Franklin)—After standing 15 years, 75,000-ton stockpile is now being loaded for shipment.

GLEN (Chisholm)—This property, idle since 1913, is about to be reopened. Men are now preparing workings and machinery.

CHISHOLM (Chisholm)—Has started to operate full time with two shifts working. Force was reduced last fall when slump came. Ore in stock is being shipped.

ROGERS-BROWN (Hibbing)—Is now shipping its ore over Duluth, Missabe & Northern instead of Great Northern. Is shipping 6000 tons daily from Buffalo-Susquehanna pit.

OLIVER IRON (Virginia)—Operations are to be increased at the Wanless, Alpena, Shiras and Mesaba Mountain mines. Another shovel will be added at Mesaba Mountain and all of ore in stock shipped.

DUNWOODIE (Chisholm)—Three shovels are at work stripping in pit. Some ore is now uncovered. It is not likely that shipments of ore will be started this year. Mine adjoins Monroe and orebody is continuation of Monroe deposit.

OLIVER (Chisholm)—This mine will not be ready to ship this year. Work of erecting the permanent mine buildings will be started shortly. Construction and development work is not being rushed as operators are in no hurry to get ore out.

EVELETH—Mines in this city are now working six days per week instead of four. Adams-Spruce property is employing about 750 men. About 350 are working underground. Five shovels are at work loading ore. Shovels in Fayal pit are also active; 350 men are employed. Leonidas is working about 100 miners underground. Conditions are better than at this time last year and most of Eveleth mines will work to capacity until fall.

MONTANA

Beaverhead County

BOSTON & MONTANA DEVELOPMENT (Elkhorn)—Development work going on steadily; tunnel is now at point where proposed crosscut will be run to central vein and work of proving up the ore will begin. Tunnel at its present face is about 1000 ft. vertically beneath surface and at 3000 ft. directly beneath mountain apex, it will be at depth of about 1500 ft.

Lewis and Clark County

MINING ACTIVITY IN THE HELENA DISTRICT—Reported that Helena Mining Bureau has transferred Eastern Bell lode to Huffaker and Hill at an advance over price in Bureau's lease and bond. Bureau has been examining number of properties in district and is now preparing to make an extensive examination of Silver King property between Helena and Clancy. This property is near old Legal Tender from which much high-grade silver ore has been taken. Estimated that more than $100,000 has been brought into this region for investment since Bureau began distributing its advertising matter.

BARNES KING DEVELOPMENT (Marysville)—Sale of Shannon property to this company was completed at Helena June 25. Actual cost of property to Barnes King is approximately $227,000, and of this amount $13,700 was paid over in cash, balance to come out of profits from ore mined. Barnes King agrees to sink shaft 200 ft. It is to be allowed $3.75 per ton for mining and milling after deducting 10% for loss in treatment. Out of first proceeds realized beyond this

amount owners of property are to receive $39,523 to reimburse them for moneys expended. After this amount is paid, profits above $3.75 and 10% treatment losses are to be divided half and half until owners of property receive $60,000. Following this payment will come final payment of $115,000 to owners of property to complete deal. Shannon mine is located close to Piegan-Gloster mines.

Silver Bow County

BUTTE-ALEX SCOTT (Butte)—Statement of net earnings of this company for year ending June 1, 1915, as filed with county assessor June 25 shows same to have been $20,000, as compared with $10,000 last year.

NORTH BUTTE (Butte)—It has been reported that company intends to increase output to between 45,000,000 and 60,000,000 lb. per annum by gradual development of recently acquired east-side properties as well as by an increased development of present workings.

BONANZA-BUTTE (Butte)—Company organized to develop Bonanza, Bonanza Extension and Ruth claims located about 4 miles north of center of Butte City and west of Moulton reservoir in Walkerville. Mayor Charles H. Lane of Butte heads new company.

ELM ORLU (Butte)—First statement filed with assessor of Silver Bow County by this company, June 24, shows net earnings for year ended May 31, 1915, amounting to $465,711. Gross proceeds from ore taken out were $1,944,983. Deductions from this were as follows: Mining, $322,074; transportation, $845,624; milling, $593,852; construction, $267,722; total, $1,488,272.

BUTTE & SUPERIOR (Butte)—Company has closed another contract, June 30, with U. S. Smelting, Refining & Mining Co. to handle 5000 tons of concentrates in addition to 4000 tons recently contracted for with same company. This will materially aid company in caring for surplus of concentrates which have been carried for past month or two. While it will not take care of entire product which company is able to turn out above other smelting contracts, it will nevertheless make heavy inroads into that surplus.

ANACONDA COPPER (Butte)—Main line-shaft floor in west half of concentrating mill at Washoe works in Anaconda was completely wrecked June 26 by an accident that compelled closing down of entire half of mill. Huge steel shaftings, driven by two 1200-hp. motors, were twisted like hairpins, and big pulleys and journals were smashed to pieces. No one was on the floor at the time of accident and its cause is a complete mystery. As result of accident capacity of concentrator was temporarily cut down by 40%, which, in its turn, necessitated the closing of all of the company's Butte mines for 24 hr. Ore on hand was sufficient to supply Great Falls plant and uninjured portion of Washoe plant. Rapid work is being done at Anaconda concentrator in getting wrecked part of mill into operation. It will probably be a week before plant will be running at full capacity again.

NEVADA

Clark County

BOSS (Goodsprings)—Platinum ore of good grade has been discovered on third level; some carrying as high as $1000 per ton in gold and platinum.

AZALIA (Goodsprings)—Shipments of zinc-carbonate ore resumed early in June, being hauled by motor truck to Jean. Road and ore-bins being constructed. In conjunction with Green Monster property, owned by Hearst Estate, is expected that this property will construct new motor-truck road to Jean.

WHALE—The option on this property held by Salt Lake capitalists was recently exercised, and the mine is being actively developed under the direction of T. A. Vardon. A compressor plant has been installed, and a tunnel is being driven to tap the vein at a depth of 300 feet. Some zinc ore is exposed in the mine and it is expected that shipments will be made in the near future.

Eureka County

UNION (Union)—Is shipping one car per day of ore to Salt Lake smelters. Ore chute is said to be 8 to 12 ft. wide and averages $14 to $50 per ton. Company is close corporation, owned in Philadelphia.

Storey County

COMSTOCK PUMPING ASSOCIATION (Virginia)—Reopening 2700 level continued.

UNION CONSOLIDATED (Virginia)—West crosscut on 2650 level continues in porphyry and quartz.

OPHIR AND CON. VIRGINIA (Virginia)—Jointly reopened old main north drift on 2500 level to 80-ft. point through caved ground.

SIERRA NEVADA AND UNION CON. (Virginia)—Jointly made good progress reopening west crosscut on 2500-level boundary line. Total repair, 214 ft.

MEXICAN (Virginia)—Mill started on June 22; crushed 70 tons of ore; average value, $15.48 per ton. Repairs on 2500 level and track laid 120 ft.

OPHIR (Virginia)—Central tunnel saved 334 cars milling ore and shipped 225 tons to mill. Andes crosscut reached footwall without disclosing pay values at that point.

JACKET-CROWN POINT-BELCHER (Gold Hill)—Mill received 921 tons dump rock; shipped one bar bullion. Fair milling values in southwest drift 1300 level of Belcher. Low-grade rock saved from Crown Point east crosscut, 1300 level.

SOUTH DAKOTA

Lawrence County

NORTH HOMESTAKE (Maitland)—Shaft is being unwatered, preparatory to resumption of exploratory work at 600-ft. level, where last work was done on property.

MINNESOTA (Maitland)—Burns & Sanford have been given contract to extend adit tunnel on Unionville claim, face of which is at present almost vertically below outcrop; additional work is necessary to intersect oreshoot on its pitch.

ORO HONDO (Deadwood)—Shaft has reached depth of 1600 ft. Two shifts of miners are employed in sinking; engineers on third shift are engaged in handling water in skips from sump on lower level to which it is lifted by sinking pump. Workings are making about 50 gal. per min.

Pennington County

COLUMBIA (Keystone)—Shaft has been repaired and sinking has commenced. Plans call for sinking to 300 ft. and the crosscutting of the formation for 1000 feet.

UTAH

Beaver County

PALOMA (Milford)—New 20-hp. electrically driven hoist recently installed.

BEAVER GOLD (Beaver City)—Horse whim has been installed at this property in Fortuna district to facilitate sinking.

LADY BRYAN (Milford)—A Knox tractor has been received in Salt Lake and will be sent to this property for hauling ore and supplies. Mine is in Star district, southwest of Moscow.

Juab County

TINTIC ORE SHIPMENTS for week ended June 26 totaled 186 cars, estimated at 9300 tons valued at $232,000 as compared with 142 cars week previous. Largest week's shipments for more than year.

Piute County

FLORENCE (Marysvale)—The Standard Chemical Co., of Toledo, Ohio, has taken an interest in the Florence company's alunite holdings and contemplates erection of potash plant near mine.

WEDGE (Marysvale)—Shipment of 24 tons of high-grade gold ore carrying some silver has just been made from this property in Horse Heaven country, near head of Bullion Cañon. Property has been under lease to J. U. Sargent, of Marysvale, who recently made shipment of six tons of sorted ore, which brought $3000. Sargent lease expired July 1. Ore occurs in fissure vein in porphyry, and pay streak has width of from ½ in. to 20 in., occurring principally along the footwall side, though sometimes on hanging. Vein was first opened by shaft and has been reached by 150-ft. crosscut tunnel, having been drifted on 65 ft. Wedge is just over ridge from alunite properties which are now being developed. N. W. Sonnedecker is superintendent, and E. P. Mowers, president and general manager.

Salt Lake County

SALT LAKE & ALTA R.R. (Salt Lake)—J. G. Jacobs, general manager, reports supplies and freight going into camp of Alta to be three times as much as year ago, which reflects increased activity in this camp and district.

UNITED STATES SMELTING (Bingham)—Judgment in favor of this company was rendered July 1 by Judge John A. Marshall in suit filed by Col. E. A. Wall, who was suing for an easement for Ashland No. 2 tunnel, on Galena claim.

UTAH METAL & TUNNEL (Bingham)—Is shipping two cars of ore daily from large orehody recently opened. Ore brings net smeltery returns of $20 to $25 per ton in silver, lead, gold and copper. Car of pyritic ore shipped recently carried over 3 oz. gold per ton.

Summit County

PARK CITY ORE SHIPMENTS for week ended June 26 totaled 2918 tons estimated at $116,000 compared to 2479 tons week previous.

Washington County

HAMBURG (Modena)—Three feet a day progress is being made in lower tunnel, being driven for vein. About 50 ft. remain to be driven.

GOLDSTRIKE BONANZA (Modena)—Four feet of ore has been opened on which good assays have been obtained. This ore was found 15 ft. below surface, where main vein is cut by cross fissure. Property is about mile west of Hamburg. C. J. Rice is superintendent.

CAMP OF GOLDSTRIKE continues to grow, there being at present population of about 200. Recent visitors include George Wingfield and party, who were in camp for several days, and Hays-Monette people of Goldfield have also been making an inspection.

CANADA

Ontario

COLUMBUS COBALT—Cross cut being run at 400 level to pick up some surface veins.

GIBSON CLAIM (Goodfish Lake)—Shaft has been put down to 100 level. Drifting and cross-cutting are being undertaken in charge of A. E. Cullen.

HURONIAN (near Larder Lake)—L. H. and N. A. Timmins have secured an extension of their option on this mine. They have 20 men sampling and prospecting and are also diamond-drilling.

DOMINION REDUCTION CO. (Cobalt)—Company has leased plant of American Eagle Mining Co. in Mimico Township for purpose of developing claims held under option in that locality.

NORTH THOMPSON (Porcupine)—Huronian Belt Co. is increasing its equipment by addition of 125-hp. boiler which will give them a total of 225 hp. The 3-compartment shaft has been put down nearly to 200 level.

VIPOND (Porcupine)—Vein on which winze was being put down from 300 to 400 level showed good width and values for 45 ft. down at which point it faulted. Crosscutting will be undertaken at 400 level to pick it up.

The Market Report

Metal Markets

NEW YORK—July 7

All of the markets were dull during the last week. Copper and tin were a shade weaker in tone, while lead was a shade firmer, and spelter experienced a rise of about ¾c. per lb. It is the common opinion that none of these changes is of broad significance.

Copper, Tin, Lead and Zinc

Copper—At the beginning of our week of record there were some important inquiries in the market which there thought to be the forerunners of a new buying movement of importance, but something or other has prevented their coming to a head so far. While the principal producers have adhered to their previous asking prices, exhibiting no concern over the absence of buying, some of the smaller producers and dealers have been desirous of selling more copper than they could place, notwithstanding their offers at material concessions. These concerns must sell copper constantly against what they take in on contract. Moreover, it has been possible to buy crude copper in the open market on terms permitting the sale of electrolytic at relatively low figures and still affording a handsome profit. The recession in the market on this business is without any broad significance, inasmuch as the buyers needing large quantities of copper could get it only by paying the prices asked by the principal producers. The latter are so well sold ahead that their present position is very firm.

The brass manufacturers of Connecticut are now said to be doing a larger business than ever before in their history, and are reported to be making important additions to their plants.

A new feature of the copper business is the negotiation of sales in Europe for copper to be delivered in the United States. Some of the brass manufacturers are unwilling to take the risk of buying copper and spelter under present conditions and will take contracts for the manufacture of brass and brass products for military purposes only upon a toll basis.

Copper Exports for the week ended June 26 were 6,955,353 lb. The chief items were 4,177,617 lb. to Great Britain, 1,120,263 lb. to Russia and 1,033,000 lb. to Italy. Imports were 6,001,879 lb. metal and 6,416,191 lb. in ore and matte; 12,417,070 lb. in all. The larger imports were from Canada, Chile, Spain and Peru.

Visible Stocks of Copper in Europe, June 30, are reported as follows: Great Britain, 22,623; France, 4670; afloat from Chile, 1325; afloat from Australia, 4300; total, 32,913 long tons. This is an increase of 2689 tons over the June 15 report.

Tin—This market was dull. Arrivals were fairly liberal but the demand was rather quiet.

Visible Stocks of Tin, including tin afloat, on July 1 are reported as follows: London, 6136; Holland, 62; United States, excluding Pacific ports, 9729; total, 15,927 long tons, an increase of 1281 tons during June.

Lead—Fair business was reported by producers, all of whom realized the price of the leading interest in the New York market, while lead in St. Louis was bought and sold at 5.60@5.67½ cents.

Spelter—Transactions amounting to several thousand tons were reported, which was rather more than in the previous week. The bulk of the business was for deliveries during the last quarter of the year. Producers were evidently aiming to sell as liberally as possible, at good prices, for such deliveries, and maintained a relatively high price for prompt and early deliveries in order to facilitate the more important transactions. The business done for prompt, July and August delivery was relatively small. Prompt spelter was offered for resale right through the week at 22c. per lb., without finding buyers. It is probable that a good deal more spelter is available for prompt delivery than is commonly supposed. The buying of last week was almost entirely confined to brass makers.

The Grasselli Chemical Co. is reported to be adding two blocks of furnaces to its Meadowbrook plant.

The United States Smelting, Refining & Mining Co. has purchased the smeltery of J. B. Kirk at Iola, Kan., and also the old dismantled plant at La Harpe. The latter is to be rebuilt with three blocks of furnaces. Including the Altoona plant, the purchase of which was previously noted, the plans of the United States company contemplate an aggregate smelting capacity of 8000 retorts, which will correspond to about 35,000 tons of spelter per annum.

Zinc Sheets are strong, base price $27 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras charged. The demand is strong and business is active.

Other Metals

NEW YORK—July 7

Aluminum—The market is rather quiet and supplies are not abundant. Prices are firm, current quotations being 32@33c. per lb. for No. 1 ingots, New York.

DAILY PRICES OF METALS IN NEW YORK

July	Sterling Exchange	Silver, Cts. per Oz.	Copper	Tin	Lead		Zinc
			Electrolytic, Cts. per Lb.	Spot, Cts. per Lb.	New York, Cts. per Lb.	St. Louis, Cts. per Lb.	St. Louis, Cts. per Lb.
1	4.7619	48¼	19.45 @19.65	39	5.75	5.60 @5.67½	19.00 @21.50
2	4.7625	48¼	19.45 @19.65	38⅞	5.75	5.60 @5.67½	19.50 @21.50
3	4.7625	48¼	19.45 @19.65	38¾	5.75	5.60 @5.67½	19.75 @21.75
5	..	...	.....	.	.....	.....	.....
6	4.7638	48	19.45 @19.65	39	5.75	5.60 @5.67½	19.75 @21.75
7	4.7688	47¾	19.45 @19.65	39	5.75	5.60 @5.67½	19.75 @21.75

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0 17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0 20c. on domestic business. The price of electrolytic cathodes is 0 05 to 0 10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are; St. Louis-New York, 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

July	Silver	Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
		Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts. per Lb.
1	22 15/16	80¼	81½	94½	20.51	170½	167½	25⅜	5.59	100	21.73
2	22 15/16	79⅛	80⅜	93½	20.31	170½	166	24⅞	5.40	100	21.73
3	22 15/16	.....	.....	.....	.....					.....	...
5	22 15/16	79⅜	81	93½	20.31	172½	168	24 3/16	5.25	100	21.73
6	22 15/16	79⅜	81¼	93½	20.31	171½	167	24 3/16	5.25	100	21 73
7	22 15/16	78⅜	80¼	93½	20.31	170½	166	24⅛	5.30	100	21 73

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4 29c.; £30 = 6 43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0 21¾c.

Antimony—A fair business has been done in buying for immediate needs. Chinese and other ordinary brands are sold at 37½@40c. per lb. The special brands are largely nominal, Cookson's being held at 50@52½c. per lb.

Quicksilver—Business has been rather quiet, and confined chiefly to moderate sales. New York quotations are $92@95 per flask of 75 lb. San Francisco reports an inactive market, with irregular quotations, $80@95 per flask being asked. London price has been dropped, and is now £15 per flask.

Gold, Silver and Platinum

Gold and Silver Movement in the United States five months ended May 31 as reported by the Department of Commerce:

	Gold		Silver	
	1914	1915	1914	1915
Exports.....	$35,867,471	$4,760,539	$20,871,093	$20,880,502
Imports.....	26,926,310	92,585,696	10,768,169	12,119,293
Excess.....	E.$8,941,161	I. $87,825,157	E. $10,102,824	E. $8,761,209

Exports of merchandise for the five months this year were valued at $1,432,811,254; imports, $708,114,681; excess of exports, $724,696,573. Adding the gold and silver gives $645,632,625 as the net export balance.

Gold sales from the New York Assay office in June were $2,743,110, being $182,540 more than in May, but $1,462,517 less than in June, 1914. For the six months ended June 30 the total sales were $37,012,497 in 1914, and $15,913,008 in 1915.

Platinum—The market remains quiet, but steady, with little change in any way. Current quotations are $37@39 for refined platinum, and $41@44 for hard metal, according to grade.

Silver has declined owing to limited buying. The exports while not up to the shipments of a year ago are still rather larger than the market can absorb on an advancing or even steady figure. Consequently recessions have been rather frequent of late with little reaction.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—July 3

The base price paid this week for 60% zinc ore was $100@105 per ton. The base price paid for 80% lead ore was $70 per ton.

SHIPMENTS, WEEK ENDED JULY 3

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	3,027,650	294,800	581,160
Year	95,154,030	3,496,890	13,785,890

Shipped during week to separating plants, 5,146,000 lb. zinc ore.

JOPLIN, MO.—July 3

Blende, high price $112.75; base per ton of 60% zinc, premium ore $110; medium to low grades, $100@95, in car lots. Calamine, base per ton 40% zinc, $75@60; average price, all grades of zinc, $97.68. Lead, high price, $73.75; base $66@60 per ton 80% metal content; average, all grades of lead, $72.98 per ton.

SHIPMENTS, WEEK ENDED JULY 3

	Blende	Calamine	Lead	Values
Totals this week	10,554,140	769,160	1,818,030	$610,500
Totals this year	299,156,030	25,958,500	44,766,250	12,376,180

Blende value, the week, $530,630; 27 weeks, $10,660,950.

Calamine value, the week, $22,620; 27 weeks, $545,280.

Lead value, the week, $57,250; 27 weeks, $1,169,950.

The shipments and settlements shown are from last week's production; the production this week of the entire Missouri portion of the district was less than 1000 tons. The first strike of general proportions in the history of the district began with the walkout of a few miners last Saturday night, and spread from mine to mine until practically every mine producing blende in Missouri was closed down by Wednesday.

Iron Trade Review

NEW YORK—July 7

The trade continues active with new orders coming in, many of them for export. Domestic business is also improving. Structural business is better, some large contracts having been placed; some of these have been under negotiations for some time past.

The pig iron market is also better, many inquiries and some orders for foundry and basic iron being reported.

Iron and steel imports on a tonnage basis in April, 1915, amounted to 16,564 tons, compared with 8025 tons in March, 1915. This increase is traceable to the heavy importing of rails, the tonnage of which in April was 8921, compared with only 430 in March. This increase, doubtless, is due to the shipments from the Algoma Steel Corporation.

PITTSBURGH—July 6

Under date of June 30 the American Steel & Wire Co. sent out circulars reaffirming prices of 1.40c. on plain wire and $1.60 on nails, thus withdrawing cut prices of $1 a ton which had become common, and not only eliminating cut prices on barb wire, but advancing prices $2 per ton above the former official quotations, making painted barb wire 1.70c. and galvanized barb wire 2.50c. The differential on galvanized nails was advanced from $1.50 to $1.75. Advances of this sort coming at the very time of year when wire products are usually dullest and weakest show the great influence of the war demand. The wire mills are said to be practically as busy now as they usually are at the height of the spring or fall season. The independent mills have concurred in the advances. Jobbers have been protected at the lower prices, but it is said for shorter periods than usual.

The large mills are not only firm at 1.25c. on bars, plates and shapes, following their withdrawal of the 1.20c. price for prompt shipment, late in June, but are now talking of a general advance to 1.30c. some time before the end of next month. Some small plate mills are still cutting the quotation of the large mills, but only to the extent of quoting 1.20c. In bars there are no cut prices. The rail mill at the Ohio works, Youngstown, and one of the Edgar Thomson rail mills are now rolling large rounds, and it is understood the Ensley mill will soon be turning out a tonnage of this important war product.

Bookings by the steel mills have been large the past few days, and July and August promise to be fuly as active as June has been. Even the June bookings, as they exceeded the June shipments, indicate an increased output in July, and from operating at about 80% of capacity in June the steel mills promise to be running at close to capacity next month. Exports of steel and manufactures of steel have lately represented about 15% of the output, but are expected to reach 20 to 25% by August.

Pig Iron—W. P. Snyder & Co. announce the bessemer average for June at $13.75, an increase of 9.1c. over May, and the basic average at $12.724, an increase of 7.4c. over May. About 15,000 tons entered into each computation. We quote: Bessemer, $13.75; basic, $12.65@12.80; malleable, $12.75; No. 2 foundry, $12.75; gray forge, $12.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—There have been sales of spot lots at $105 and perhaps at slightly higher figures. Contract continues at $100, seaboard.

Chemicals

NEW YORK—July 7

The general market is quiet, but in some lines considerable activity is apparent.

Arsenic—About the usual business is forward and prices are unchanged at about $4 per 100 lb. for both spot and futures.

Copper Sulphate—The market shows a fair demand and prices are steady at $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller parcel.

Nitrate of Soda—Demand is better and the market is stronger. Current quotations are firmer at 2.35c. per lb. for spot and for all positions this year.

The total indebtedness of the nitrate producers to the Chilean Government under the system of advances adopted in 1914 was $2,880,000, U. S. currency, on May 15. The total amount loaned was $3,356,000, of which $476,000 had been repaid.

Sulphate of Ammonia—The production of sulphate of ammonia in Great Britain in 1914 is reported by the Alkali Works Inspectors as follows: Gas works, 175,930; iron works, 16,008; oil-shale works, 62,749; byproduct coke ovens, 137,430; producer gas and carbonizing works, 34,295; total, 426,412 long tons. The total compares with 432,618 tons in 1913, showing a decrease of 6206 tons; and with 388,308 tons in 1912, an increase of 38,104 tons.

PETROLEUM

The monthly statement of the "Oil City Derrick" shows new wells completed in June as follows: Pennsylvania grade, 240; Lima-Indiana, 30; Central Ohio, 73; Kentucky, 11; Illinois, 54; Kansas-Oklahoma, 304; Texas-Louisiana, 191. In all 903 wells were completed in the fields covered by the report, a decrease of 55 from the May figures. New production amounted to 161,279, or 12,922 less than in May. Among the completions were 231 dry holes and 127 gas wells, an increase of 34 and four, respectively. At the close of June 465 rigs and 1592 drilling wells were reported.

Exports of petroleum from Mexico in May were 1,289,173 bbl., an increase of 85,950 bbl. over April

The Engineering and Mining Journal

VOLUME 100 JULY 17, 1915 NUMBER 3

Orebodies of the Mesabi Range—I

By J. F. Wolff*

SYNOPSIS—Supplies additional information to the literature on the Mesabi orebodies. Geologic section. Characteristics of the several formations. Typical structure of orebodies. The layers of ore and waste material in the ore concentrations.

The geology of the Mesabi range has been described most exhaustively in the U. S. Geological Survey monographs Nos. 43 and 52. In 1913 the University of Minnesota published a bulletin entitled "Iron Mining in Minnesota," which contains a great deal of valuable information regarding the range. Numerous articles have appeared in different mining papers and particularly in the *Journal* of late regarding Mesabi range mining practice. Notwithstanding all these publications, some indefinite ideas obtain regarding the structure of Mesabi orebodies, not only among mining men not engaged in work on the range, but even among some directly connected with the work. The two Geological Survey publications referred to are so technical geologically that perhaps few practical mining men read them thoroughly. The University of Minnesota bulletin mentioned is valuable to the practical man and should be in the hands of everyone interested in the iron-mining industry. But in none of these publications is the structure of the orebodies described or emphasized in such a way as to be of practical value to engineers in the district.

In order to present a practical and untechnical summary of what is known of the physical structure of these orebodies, in such a way as to be of direct value to men in the district, and to present many newly discovered facts hitherto unpublished, this series of articles has been prepared according to the following outline:

I. General Geologic Structure
   a. General geology.
   b. Typical structure.
II. Actual Orebodies as Developed.
   a. Sections of developed bodies from different parts of the range.
   b. Special sections showing monoclinal folding and large faults.
III. Exploration and Development.

*Mining engineer, Oliver Iron Mining Co., Duluth, Minn.

IV. Geologic Formation
   a. Three types of orebodies: (1) Trough bodies, (2) flat-layer bodies, (3) fissure bodies.
   b. Geologic conditions causing these three types of orebodies.

These articles present information drawn from a great many sources, from exploration and operating records of the different mining companies and from personal investigations and studies of many engineers in the district.

It is not the purpose here to enter into any details of mining practice or engineering work, beyond the exploration of orebodies and the interpretation of such exploration records, although Fig. 1 shows a typical steam-shovel operation in the Mahoning pit. The practical value of these articles to the engineers in the district will consist of the explanation of how to work out most accurately the structure of the bodies from the results of the drill explorations. A fairly uniform practice in this matter is followed by several mining companies, but it is believed that the present articles will add considerably to general knowledge on this subject. In Fig. 2 is presented a map of northern Minnesota showing the extent and horizontal configuration of the Mesabi range with its relation to the other Minnesota ranges, the Vermilion and the Cuyuna.

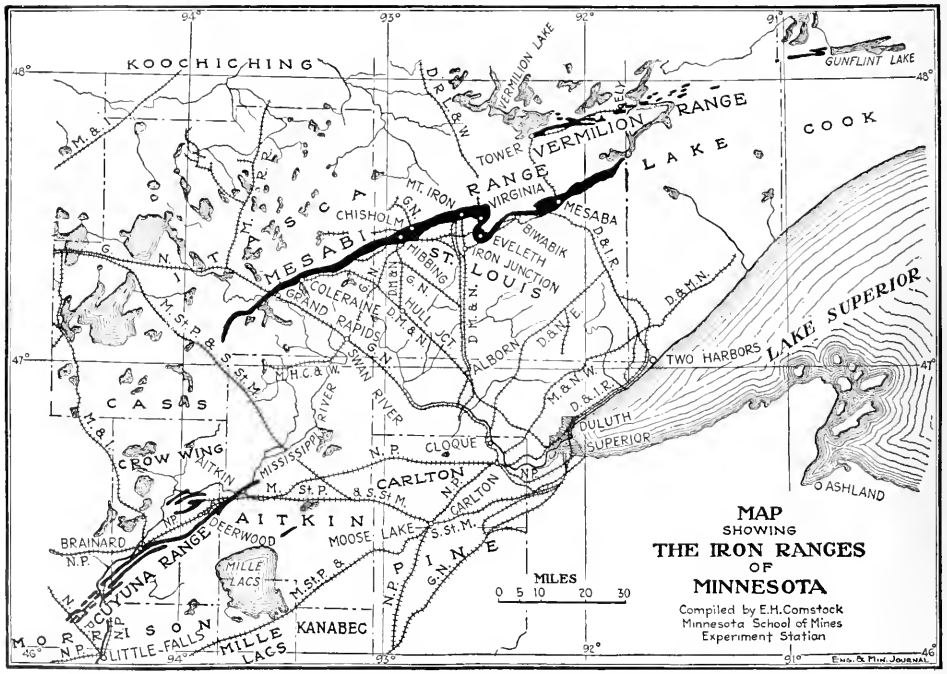

FIG. 2. MAP OF NORTHWESTERN MINNESOTA, SHOWING THE IRON RANGES

Geologic Structure—General Geology

A short statement of the general geology of the Mesabi district is a necessary introduction. The iron formation of the range has been traced by explorations from Sec. 12, T. 142 N, R. 25 W, northeastward to Birch Lake, Sec. 26, T. 61 N, R. 12 W, a distance along the strike of about 112 miles. Its width varies from ¼ to 3 miles.

The topographic feature of the range is a line of fairly prominent and continuous hills north of the iron formation. These hills have been called "Giants Range" from early days.

As correlated by the U. S. Geological Survey and amended, the rock formations of the district consist of the following, arranged from the top down:

Quaternary system
  Pleistocene series .....Glacial drift, 0 to 306 ft. Uncemented conglomerates.
Unconformity.
Cretaceous system
  Conglomerates and shales....0 to 50 ft
Unconformity.
Paleozoic group (?)
  Conglomerates or rubble ore..Fragments
Unconformity.
Algonkian system
  Keweenawan series .....Great basal gabbro (Duluth gabbro) and granite, (Embarrass granite), intrusive in all lower formations.
Unconformity.
Huronian series
  Upper Huronian series:
    Acid and basic intrusives.
    Virginia slate .....0 to great thickness.
    Biwabik iron formation .....760 ft
    Pokegama quartzite.50 to 150 ft.
Unconformity.
  Lower-Middle Huronian series:
    Giants Range granite (intrusive).
    Slate-graywacke-conglomerate formation (equivalent to the Ogishke conglomerate and Knife Lake slate of the Vermilion district).
Unconformity.
Archean system
  Laurentian series .....Granites and porphyries.
  Keewatin series .....Greenstones, green schists and porphyries.

Those familiar with the Geological Survey publications will notice that a Paleozoic group has been introduced here. Close observation by mining engineers on the range has disclosed the fact that there are on the tops of some orebodies one or possibly two conglomerates much

older than the Cretaceous. On one orebody a coarse rubble ore is found so firmly cemented that it is as difficult to break as the original taconite. It certainly is much older than Cretaceous. In another place under 50 ft. of Cretaceous shale and conglomerate is found a conglomerate much harder than the Cretaceous and of different appearance. From this evidence the Paleozoic is introduced.

For the engineer in the district it is not at all necessary to keep in mind the foregoing series and the following geological column is far simpler and entirely sufficient for practical purposes:

Glacial drift
Cretaceous shale and conglomerate
Virginia slate (black slate).
Biwabik iron formation (ferruginous cherts, taconite, and interbedded slates with orebodies).
Pokegama quartzite (granular quartzite, quartz-slate and "flaky" sericitic quartz-slate).
Basement complex of granites, slates, conglomerates, and green-stones.

The possibility of intrusions into the iron formation should be kept in mind also.

Referring to this simplified geologic column, Fig. 4 shows a generalized cross-section and explains the relative positions of the series better than a long description could. From a commercial standpoint the Upper Huronian series, namely, the Pokegama quartzite, the Biwabik iron formation, and the Virginia slate are the important rocks of the district. This series rests unconformably upon the older rocks and slopes away from them to the south and southeast at low angles, 5° to 8°, although locally steep dips are observed. It is obvious that it consists of sedimentaries which therefore have practically parallel bedding. This fact should be emphasized and remembered. At the base of the Biwabik iron formation and resting on the Pokegama quartzite is a conglomerate varying in thickness from a few inches to 15 ft., indicating a slight unconformity. At its top the iron formation has a sharp though conformable contact with the Virginia slate. U. S. Geological Survey publications state that in places the quartzite is absent and the iron formation rests upon the older rocks. More than 300 miles of drilling by mining companies fails to reveal the absence of quartzite at any place.

The quartzite varies in different places from disintegrated, granular quartzite to a compact, granular quartzite, to an extremely fine-grained, dense quartz-slate and to a "flaky" or sericitic quartz-slate. Failure to recognize these different phases as being the true Pokegama formation has caused different explorers to drill completely through the quartzite into the underlying granite, slate or greenstone. Assays of the quartzite have run as high as 33% iron, causing the explorers to think the formation was the true taconite, the local name for the ferruginous chert of the Biwabik iron formation. This mistake always can be avoided by watching the drill cores for the gnarled jasper and conglomerate at the base of the iron formation and on top of the quartzite.

Iron Formation and Intermediate Slate

The iron formation (Fig. 6) consists principally of iron-bearing chert, called taconite, interbedded with both thin and thick layers of gray, green and black slates. Its greatest known thickness is 760 ft. From 150 ft. to 285 ft. (in rock) above the quartzite is the bottom of a main slate layer varying in thickness from 10 ft. to 50 ft., although locally it has a uniform thickness. On the eastern end of the range this distance is 150 ft. or a little more; in the central part it is 180 ft. to 285 ft., averaging about 200 ft. This slate is known as the Intermediate slate and is an important horizon in the formation, as will be shown later. Interbedded with this slate are lenses of taconite. Below the slate is a layer of taconite, yellow in color where altered, from 10 ft. to 50 ft. thick. It grades downward into true gray taconite or ferruginous chert. Its top, the contact with the Intermediate slate, is extremely sharp. Near the bottom of this yellow taconite in some parts of the district there is an interbedded conglomerate.

Above the Intermediate slate is a horizon of slaty taconite 15 ft. to 50 ft. thick, more thinly bedded than the lower yellow taconite. This is really the gradation from the Intermediate-slate layer into the upper taconite and is not sharply defined. Above this layer or horizon is a great thickness, 300 ft. to 500 ft., of "cherty" taconite, as distinguished from "slaty" taconite, in which are interbedded both thin and thick layers of gray slate, not so dark generally as the Intermediate slate. The princi-

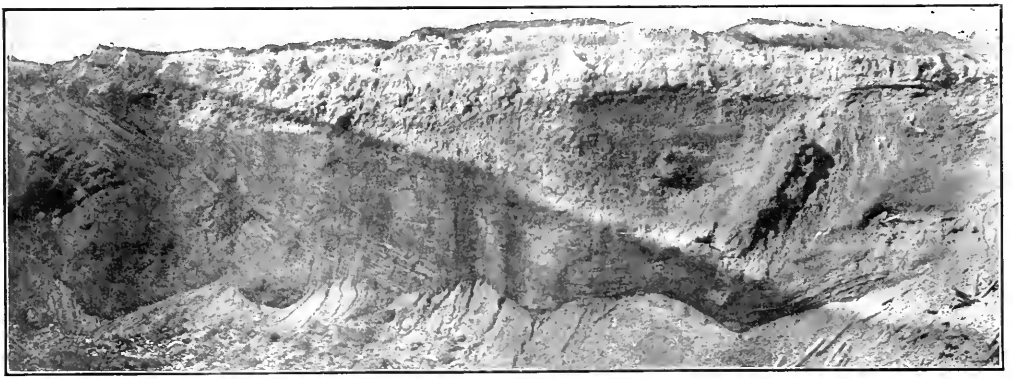

FIG. 3. FACE OF ORE AT NORTH END OF AGNEW MINE, HIBBING DISTRICT

Note the marked slump of ore layers. The orebody is a small trough tributary to a large one. At the right end is a drag fold. On top of the ore is a bed of Cretaceous conglomerate covered by drift

pal one of these slate layers is from 20 ft. to 75 ft. thick and its top is about 135 ft. to 175 ft. above the bottom of the Intermediate slate. There is danger of confusing this slate with the Intermediate slate in drill cores unless all the drill holes are correlated as drilling progresses. If the hole is put down through the Intermediate slate, the two slates will be distinguished readily because of the presence of the lower yellow taconite, usually considerably decomposed, beneath the Intermediate slate.

This slate and slaty-taconite series may be considered broadly as a slate horizon interbedded with the taconite. Its total thickness is 175 ft. or less and its lower 40 or 50 ft. usually is most distinct.

At its top the upper cherty taconite is interbedded with more slate and finally gives way to a fine black slate, the Virginia. Thus, as previously indicated, the taconite or Biwabik formation grades upward into Virginia slate, although the actual contact between the two is well defined. The interbedded slates represent periods when, due perhaps to the rising of the land area north of the shore line, the rivers became more rapid and erosion more active and increased amounts of mud were transported to the sea or lake in which the iron formation was being deposited.

In the eastern part of the district a marked conglomerate 10 to 30 ft. thick is found some distance above the top of the slate horizon just mentioned. Two distinct conglomerates are also found within the slate horizon.

An understanding of the structure just described, and illustrated in Fig. 6, is essential to the correct understanding of the structure of the orebodies to be described later, since the two are genetically related.

The source of the iron in the taconite need not be reviewed here; it is discussed at length in monographs 43 and 52. It is sufficient here to recognize the quartzite-iron-formation-slate series as an ordinary series of clastic sediments (except for the iron) deposited in fairly shallow water, contemporaneous with which an enormous quantity of iron was deposited or precipitated out of solution. It has been shown that most of the iron was originally in the form of ferrous silicate, $FeSiO_3$, occurring as minute green granules of the mineral greenalite, embedded in a matrix of chert. Iron carbonate is present in small quantities.

The iron formation probably was covered completely by the Virginia slate before earth movements caused the series to be raised above the water. When this occurred, erosion at once started, cutting through the overlying slate and exposing the iron formation and quartzite. Thus exposed to ground waters and oxidizing agencies, the ferrous iron of the iron formation became oxidized and the great mass of the iron formation was changed from a greenalite-chert rock to an iron oxide-chert rock, the present taconite or ferruginous chert. The iron oxide is in the form of minute granules (oxidized greenalite grains) and of small irregular masses and layers. This change or primary concentration must have taken an exceedingly long time. The earth movements which raised the Mesabi rocks above water also caused considerable folding, cracking and faulting of the rocks. Where cracks were numerous ground water found its way into the formation most easily. These waters, by means of the CO_2 and other solvents they carried in solution, attacked the silica in such favorable places, dissolved it to a large extent and carried it away in solution, leaving in place the stable iron oxide. This secondary concentration in favorable locations has produced the orebodies as we have them today. The process was a simple one; the leaching out of the silica left the iron oxide of the taconite in place. This removal of silica left voids or pore spaces and decreased the volume. The residual ore slumped or compacted itself of its own weight; this slump is a marked feature in almost every orebody (Fig. 3). Some further oxidization of iron probably occurred at the same time. The orebodies thus formed are of the greatest variety of size and shape. Their total known area is more than 15% of the total area of explored iron formation; their volume is a much smaller proportion. The size, shape and formation of the orebodies will be discussed at greater length in Part IV.

The average iron content of the taconite is about 26%.

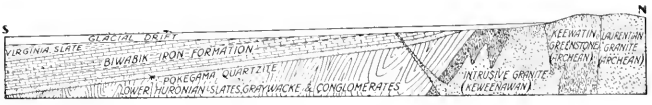

FIG. 4. GENERALIZED CROSS-SECTION OF THE MESABI RANGE LOOKING WEST

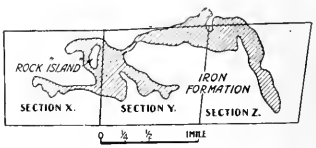

FIG. 5. TYPICAL SHAPE OF AN OREBODY

The average of all ores above 50% iron is between 58% and 60% dried at 212° F. The principal mineral in the ores derived from taconite is hematite; in those from slaty taconite, limonite. The alteration of the interbedded slates makes "paint-rock," a mixture of extremely fine, "powdery" hematite and limonite in a mass of soft clay.

Cretaceous Conglomerate and Shale

In practically all parts of the district are found remnants of a Cretaceous series overlying unconformably the iron formation and the Virginia slate. This series consists of a basal conglomerate of coarse pebbles of iron ore several inches or several feet in thickness, grading upward through a fine conglomerate into a true shale. In some places this shale averages 50% dried iron. Shells and vertebrae and teeth recognized as those of a variety of shark, mosasaur, are found in the shale. In most places the conglomerate is poorly cemented with a siliceous-aluminous material, a true clay. Several bodies of this conglomerate 15 to 30 ft. thick, each containing several hundred thousand tons, have been found by drill explorations. They overlie the Virginia slate or the contact of slate and iron formation; in a few places they cap the other orebodies. Their content is from 50% to 54% dry iron; their alumina content is high, from 6 to 12%. Phosphorus is also notably high, due to organic remains. In preglacial erosion channels and probably old shallow lake basins on top of the iron formation, poorly assorted

uncemented conglomerates of iron-ore pebbles are found. These conglomerates are much younger than the Cretaceous.

Glacial Drift

Covering the sedimentary rocks of the district almost entirely is a mantle of glacial drift varying in thickness from a few feet to over 300 ft. The average thickness over the orebodies developed as openpits is 50 ft. As can be seen in the banks of the openpits, this drift consists of a lower and an upper layer of typical glacial till, between which is a layer of stratified sands and gravels. These latter probably were deposited in a marginal glacial lake, while the former are the ground moraine of two different ice-sheets. This complete series is not found everywhere in the district.

With the foregoing statement of the general geology of the district as a basis, the detailed structure of the orebodies may be considered.

Typical Structure

Three types of orebodies are found in the district, namely, trough bodies, flat-layered bodies and fissure bodies, named in order of their importance. These three types and the conditions of their formation will be discussed in part IV. By far the greater part of the ore occurs in trough bodies; therefore the structure of the trough bodies will be described and illustrated as the typical structure of Mesabi orebodies.

The process of formation of the orebodies as explained in the foregoing discussion developed great troughs in the iron formation, in which the orebodies lie. Some of these troughs are small and isolated, but for the most part they are connected into enormous irregularly shaped bodies. Amoeba-form is the best descriptive word for their shape in plan. Fig. 5 shows the area of such a body. The main body has a trough basin and the individual fingers or lobes each has a trough structure. The main axis of each trough is roughly parallel to the strike of the formation, but the axes of the minor troughs are at all angles to the strike. For purposes of illustration the structure of the minor troughs will be considered. Fig. 7 is a section of a minor trough taken at right angles to the longitudinal axis; it shows the typical structure of a Mesabi orebody. Fig. 6 shows the typical structure of the iron formation where unaltered to ore. A comparison of the two figures discloses at once the direct relation between the structure of the country rock or unaltered iron formation and that of the orebody. The Intermediate slate becomes intermediate paint-rock, the upper slaty taconite and lower yellow taconite become upper nonbessemer and lower nonbessemer ore layers respectively, and the upper and lower cherty taconite are altered to upper and lower high-grade (generally bessemer) orebodies, respectively.

The ore of these high-grade bodies is generally referred to as blue ore, from a slightly bluish cast which it has in the bank.

Fig. 7 is an actual section of an orebody now nearly mined out, except that the width has been reduced 200 ft. in the figure. As is evident, a large thickness of the formation above the Intermediate layer has been removed by glacial and preglacial erosion. Attention is called to the marked slumping of the layers in the middle of the trough and at the contact of the ore with the rock walls. This was previously explained and, as stated, is a marked feature of Mesabi orebodies. At every rock and ore contact it is observed. The seams of ore often can be followed turning up and connecting with ore seams in the rock. In deep troughs the ore layers have slipped down many feet along the rock wall. So persistent and pronounced is this slumping that the presence of underlying rock pillars or the outline of a lower rock wall can be known quite accurately by observing the slump of the ore layers in either underground or openpit workings.

The ore of the upper high-grade body is characteristically fine grained and contains numerous seams and layers of paint-rock, resulting from the alteration of the interbedded slate seams and layers. Little rock, taconite, is found in this body. Mineralogically hematite predominates, but many of the paint-rock seams are limonite.

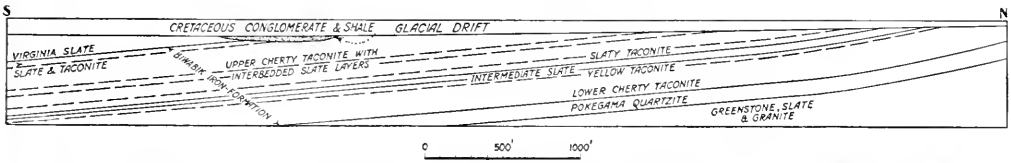

FIG. 6. GENERALIZED CROSS-SECTION OF THE MESABI RANGE, SHOWING GEOLOGIC FORMATIONS AND SUBDIVISIONS OF BIWABIK IRON FORMATION

The ore of the lower high-grade body is much coarser than that of the upper and contains but few seams of paint-rock as compared with the upper. It consists principally of hematite. Most of the lower orebodies so far developed contain considerable rock; their silica content for the same grade of iron is higher than in the upper orebody. This indicates that the alteration and concentration have not been so complete below the intermediate layer as above it. The rock occurs as layers or lenses and as pillars. If large, the pillars are called "horses" of rock or taconite islands. In some cases these rock pillars stand up like slender pyramids. In others the base is found to be altered to ore and they fall over or are blasted down in mining operations in openpits. In many orebodies the lower 10 to 25 ft. of the lower high-grade orebody is exceedingly sandy, making it really a low-grade ore. In such bodies the high-grade ore grades downward through sandy and decomposed taconite to the bottom solid taconite. In other bodies the contact of high-grade ore and bottom rock is sharp. Monograph 52 states that in no place does an orebody rest upon the quartzite. Recent drilling has shown that several orebodies in the western part of the district rest directly upon the quartzite. As early as 1906 part of the orebody of the West Gilbert mine was known to rest on the quartzite. Mining operations have shown that the top 5 ft. of the quartzite, not the conglomerate above it, is so impregnated from the ore above that it analyzes over 50% iron, dried.

The upper nonbessemer layer is an alteration of slaty taconite, is quite soft in texture and finely laminated. It is composed of layers of limonite and a little hematite, the latter occurring in the layers of purplish paint-rock.

The lower nonbessemer ore differs from the upper nonbessemer chiefly in texture. It is derived from a true taconite or chert rather than from a slate. The ore is chiefly hematite; but there are enough limonite streaks in it to give it a yellow color. In texture it is nearly as coarse as is the underlying high-grade ore. Both upper and lower nonbessemer layers are called locally yellow or brown ores, from their appearance. The lower nonbessemer ore cannot in any way be considered as the alteration of the lower part of the Intermediate slate, because the break between the latter and the yellow taconite from which the lower nonbessemer ore is derived is the sharpest division in the Biwabik formation. In fact, as will be shown later, this very break is used to work out the structure of orebodies from drill records and drill cores. As previously indicated the upper nonbessemer ore is a gradation from the Intermediate paint-rock layer into the upper high-grade ore.

The Intermediate slate layer becomes altered to the Intermediate paint-rock layer in an orebody. The paint-rock is a soft, clayey layer, from 5 to 50 ft. thick. The predominating color is red, although there are numerous thin yellow, brown and purplish layers in it. It has a high moisture content and samples taken from it are exceptionally high in alumina and usually in phosphorus also, although there are local exceptions to the latter rule. The iron analyses for the paint-rock layer given in Fig. 7 cannot be compared directly with those of the yellow and blue ores because the moisture in the paint-rock is 50% to 100% more than in the blue ores. Analyses given in Fig. 7 are dried at 212° F. The paint-rock is not a commercial ore; its natural iron is too low, ranging from 35% to 43%.

The high-grade bodies have been referred to as generally bessemer orebodies. In many cases, however, the phosphorus is too high to class them as bessemer. The lower orebody is more uniformly bessemer than is the upper. This is probably due to the greater abundance of paint-rock seams in the upper body (the slates carry higher phosphorus than does the chert), and also to phosphorus precipitated out of solution from ground waters.

Since a 40-acre tract is the unit of ownership on the Mesabi range the complete typical structure does not appear in every such tract. In many places glacial and preglacial erosion has removed part or all of the upper orebody, intermediate paint-rock layer and lower nonbessemer, leaving only part of the lower orebody. In places such erosion leaves the paint-rock layer capping the orebody. In a few cases, including one exceedingly large orebody, there is no alteration below the Intermediate slate, and this layer is the foot wall of the orebody. Then there are extensive flat-layered orebodies which are below the Intermediate slate and there is little or no ore above it.

In Secs. 2 and 3, T. 58 N., R. 15 W a granite intrusion in the iron formation below the Intermediate slate forms the foot wall of the orebody of the Meadow mine.

The typical structure above described applies to the orebodies from one end of the range to the other. It was first recognized by John Uno Sebenius, now general mining engineer of the Oliver Iron Mining Co., in the early days of Mesabi exploration. He carried samples of the Intermediate slate from one part of the range to another in order to establish the continuity of this layer. He compiled the first map of the district and the map published by the U. S. Geological Survey is practically a copy of his map, which has been added to and corrected as explorations progressed. His geologic and mining work in the district make him the foremost authority on the Mesabi range. I am indebted to him for permission to use much of the information contained in these articles. I am also indebted to the officers of the Oliver Iron Mining Co. for permission to publish these articles and to use data from which they have been prepared. The great mass of information collected by them since the early exploration of the Mesabi range has been accessible and without such data the facts presented in these articles could not have been worked out. I take credit only for the close study and correlation of this information and observations in operating mines all over the range. Special acknowledgment is due also to associate engineers in the Duluth office for helpful suggestions and criticisms.

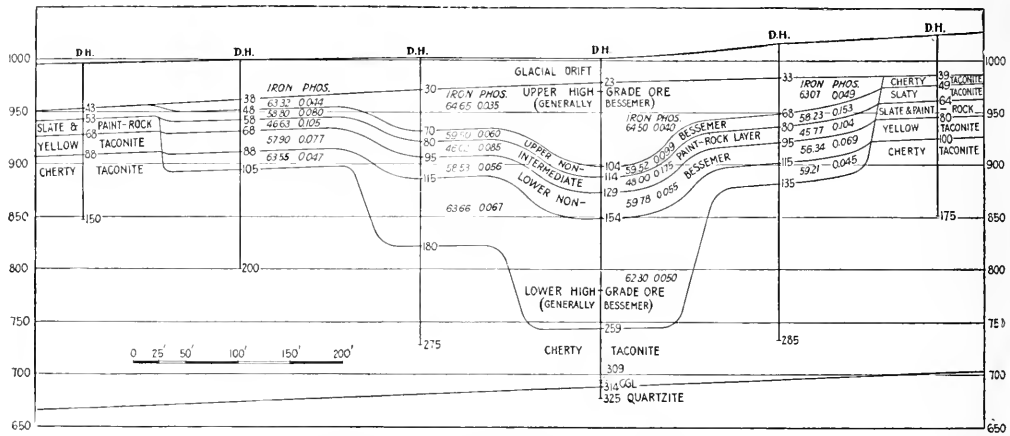

FIG. 7. CROSS-SECTION OF A TROUGH OREBODY, SHOWING TYPICAL STRUCTURE AND ANALYSES OF ORE

(To be continued)

Zinc Corporation and the War

SYNOPSIS—Besides financial tension and disturbed markets, the war closed the outlet for the Zinc Corporation's zinc concentrates which had been smelted in Germany. The chairman reports that the corporation's effort to dispose of its products was further embarrassed by the inability to get a decision from the British courts as to whether its contract with an alien enemy was merely suspended or was canceled.

The difficulties arising out of the war for Australian companies that were having their zinc concentrates smelted in Europe are set forth in an interesting address by Chairman F. A. Govett to stockholders at the recent annual meeting of the Zinc Corporation in London. The chairman said in part:

This company is one of those which has suffered very hardly with the incidence of war—a world-wide war, with all its diverse and far-reaching effects. Some companies and some individuals are making largely increased gains, while others, like ourselves, have been condemned to struggle with adverse conditions to maintain some decent profit, some even to keep alive. Not only have we had to deal with direct troubles in total suspension of our sales of zinc concentrates and in difficult markets for our lead production, but also indirectly, in that we were involved in legal difficulties in our contract with an alien enemy, while, in full and reasonable anticipation of continued peace—for who last summer thought of war, and such a war as this?—we found ourselves surprised, with our financial resources tied up, with our wealth unrealizable, even if our credit was and still is unimpaired. This position, of course, entailed, as we informed you in our circular, the postponement of the final instalment of the preference dividend, which now we pay.

When confronted by factors of sufficient magnitude and great complexity, it is fair to say that none of us are more than theorists or empirics in times like those at the beginning of the war. There was no man—banker, merchant, chancellor or financier—who could do much better than make a hesitating guess at what would happen as a result of any step; consequently, we have passed through many stages of moratorium and questionable relief, including national assumption of hundreds of millions of doubtful bills and attempts to establish here the industries of other countries with no determination to protect them till established; in fact, we have passed through a whole gamut of tentative expedients, and even now the exchanges of the world are in disorder and the financial conditions in some countries—certainly in one, in which we are financially interested, Canada—are still difficult, uncertain and confused.

Lead-Smelting Contract Suspended

I will come back to this point in dealing with our financial position, but first I must trace our history from the outbreak of the war. At that time it was in our judgment probable that while our sale of zinc concentrates was obviously totally suspended, some considerable demand for lead would be continued, and with that idea we kept our lead concentrator in full operation and closed down the zinc. That view was not shared by other people; in fact, I think we were alone in taking it, for the other mines at Broken Hill only worked half time, and that only in order to keep labor employed, while the Broken Hill Proprietary, with whom we had our contract for the sale of our lead concentrates, notified us in consequence of war of suspension of our contract. At first we were under the impression here that they must actually have stopped smelting, in which case the suspension, of course, was justified. Under this impression we issued our circular last September.

It was only later, to our intense surprise, that we found they had never ceased to work full time. Then we protested, for, as the war had not interfered with their working at Port Pirie, the war clause in the contract plainly could not apply. I do not like to suggest that they seized a very thin opportunity to rid themselves of an onerous contract, but we regard the suspension simply as outrageous. The result was that we were forced into a position of either having to put up with what we considered an illegal and unwarrantable suspension of our contract—for the group with whom they had made a working arrangement during the war would not admit us to share in the arrangement for smelting at all unless we accepted that position—or we were left with no possibility of smelting our present output, and with our sole remedy an action against the Proprietary, which, under the circumstances, would have placed us in a most invidious position. In Australia such an action would have been regarded as mean and unpatriotic, for this arrangement with the North and South was primarily an arrangement to keep labor employed, although it has turned out very profitably for those companies. We do not like law, however sure we feel; we wanted to keep our labor employed; we had to sell our concentrates, and therefore we had to put our pride in our pockets and to accept the share which they offered. We were just in a cleft stick.

Coöperative Smelting Arrangement

I am not going to reargue further before you our view of this question, but under this compulsion and our immediate necessity we accepted a four-eighteenths participation and again began to earn some revenue. But I would like to call your attention to the fact that our view of the future of lead sales was right; the demand, of course, has not been normal, but at this moment the price of lead is much higher, and the demand, I think, is going to continue. Now, however badly we may think we have been treated by the Proprietary people, I think this is going to work out "somehow good," for at least there is some sign of real concerted action in lead production and in the selling of lead from Broken Hill. While I am on this subject I may as well deal with the proposal which was before us and which we have accepted. It is this: A company has been formed of £700,000 issued capital, to take over and work the Proprietary smelting works. The purchase price is £450,000, payable as to £300,000 in cash and £150,000 in shares. It appears there is £250,000 working capital. Toward this £550,000 cash the Proprietary subscribed £50,000, which leaves £500,000 in cash to be provided. This is subscribed by the North and South and ourselves.

It is understood that this is to be regarded more as a coöperative scheme than as a commercial enterprise to pay large profits, its object being to treat the Broken Hill output as far as possible as a whole. There will always necessarily be exceptions—for instance, the Sulphide Corporation has smelting works of its own; but this is the first genuine attempt at combined operation, and we regard it as most important, for it should establish the combination in a powerful position as regards the lead markets of the world. We had, therefore, no hesitation of any sort in accepting our share in this combination. The proposal is that this company will also smelt for outside companies, the returning charge being based on a reasonable profit to provide for interest on capital and amortization. That helps to make the money involved secure, and, even if we get no extravagant dividends from our investments, we shall get the equivalent in whatever increased profit there may be in the realization of our concentrates, for the smelting company will control the operations of marketing the lead, and this is an important move in the direction of shaking free from the domination of foreign control of the metal markets of the world. Our participation was necessary, for if we did not participate we could not smelt our concentrates; no matter how we raised the money, we had to take our share, and, therefore, we did not worry you with earlier discussion of this matter.

Alien-Enemy Contracts

I now pass to the zinc position, and here there is involved the question of alien contract. Prior to the war, as indeed you know, we sold our concentrates to German buyers, who, of course, at once notified us of suspension. I think the first three months of the war was spent by H. C. Hoover and myself in a continuous study of this zinc position with a view to finding other outlets, and in consideration of the question of the erection of smelting works here, while Theodore Hoover was in America studying the position of zinc smelting there. Counsel's opinion was at once taken as to these contracts being void, and while the authorities over here seemed all agreed that the contracts actually were void, it was not a positive fact, for there had been no decision and there seemed no way to get a decision, which first was absolutely necessary, seeing the magnitude of the sums involved. We made a gallant effort to get a declaration from the Special War Court of Appeal, but when we appeared in court before six judges they pleasantly told us they could not hear the case as we had not brought the alien enemy into court. While this embarrassing and paradoxical decision may have pleased and satisfied the legal mind, it fairly blocked our road, and the only alternative before us was to wait for state declaration that such contracts are void. The Australian Federal Government appeared to be anxious to take this course, and I interviewed the High Commissioner and bombarded the Colonial Office and the Board of Trade to take joint action, but so far without effect beyond this, that a short act was passed in March making it possible to bring an alien enemy into court by substituted service, and we are now engaged in another attempt to grapple with the difficulty.

This question of the alien-enemy contract was and is of the last importance to this company, for if these contracts were not void beyond all question, but possibly only suspended, it was not open to us to build smelting works for ourselves, nor could we make other contracts, and lastly, unless happily we can get our declaration of avoidance by the act of the Federal Parliament, or by assistance of this short act of which I spoke just now, it looks as if we may be sooner or later involved in lengthy litigation and this litigation might keep us out of business for another period. So much for the legal point. It is not easy to see the present price of spelter and not to feel wild that we are not able to sell our concentrates and take advantage of the price; but one should reflect that the price exists only because we cannot sell, and that if we could the price would not be there.

Temporary Zinc-Smelting Works Impracticable

It has been suggested to us once or twice that in order to get some benefit from this abnormal price, we should run up a cheap temporary zinc smelting plant quickly. I fear the answer is that it would take a year to erect any kind of a new plant, and there is no such thing as a cheap make-shift smelting works; so that unless you think the war is going to last, that suggestion is no use, while as regards the practical point of erection of smelting works, it would be difficult here to get the labor to erect, or when erected, the skilled labor required to operate; while generally, apart from war conditions in England and Australia, frankly I doubt if this policy can be justified. There were in existence before the war even more smelting works than were required to produce the consumption of the world in spelter. To add to their number, except perhaps to a small extent by way of a "control" plant, which would enable us to compare results, would simply mean to increase the competition and depreciate the price of spelter. Before the war many of these plants in America and Holland were actually shut down, and except for patriotic desires it would not seem sense to increase the number unless it be to supply our home consumption, and this only with a full determination to protect the industry, when established, from destructive, certain competition.

These plants are expensive to erect; a plant to handle our production of concentrates alone would cost £500,000, leaving out of consideration the capital necessary to carry and finance the business. Notwithstanding these portentous figures, we spent the first three or four months of the war practically in this continuous study of the problem; we examined various sites all over England, and have had negotiations with the leading smelting people, and others, in the United States, here in London and elsewhere. The president and the engineers of one of the leading companies specially came over, but we could not agree on remunerative terms. But so far as the erection of works is in question, our conclusion is that in the absence of protection or some state assistance, our policy must be, on conclusion of the war, to make some new contract on equitable lines with some existing smelting works. This perhaps may seem a pity, for, in our group, which includes the Burma Mines, we have two mines which look like a sufficient permanent assurance of supply of zinc ore. That is one of the difficulties—the permanence of supply. That, we think, is one of the conclusive reasons why smelting works of any size cannot be erected in Australia, for as the accumulated mountains of tailings disappear—and the progress of disappearance is fast—the current supply of tailings would be insufficient to justify erection, the later supply not being assured. Be-

sides this, there would be the expense of highly paid labor, and the business would not stand it. I think that explains the position as it is likely to be at the end of the war.

Sale of Zinc Concentrates

So far as regards the present we have also had plenty of negotiations for temporary contracts, but without result. We put forward what was admitted to be a reasonable plan with one of the leading American companies, whereby both we and the purchasers could share equitably in the profit resulting from high-priced spelter, but constantly we were met with the objection that other Australian concentrates were offering on very much easier terms. As recently announced, the Amalgamated Zinc has made one small sale—I fear on not good terms—so that I can only conclude that the other companies between them previously must have all but spoiled the whole business, for the only definite terms which I have heard, and on which a contract was actually effected, were such as we should not accept. None the less, I am pleased to say we think we have succeeded in selling 14,000 tons on terms which are satisfactory to ourselves, and we have some hope that this may be followed by other sales. I am not in a position at present to say more than that, for the business is not definitely complete; still I hope that it may enable us to start working, at any rate on some reduced scale or for a time. But it would be no use estimating possible profits under present conditions.

Lead Operations Profitable

We are, however, doing well with lead, for with the present demand for lead we suppose the full production of the smelters is being sold. Against that, however, at present we are working short time, for the production of concentrates has overtaken the smelting works which will be enlarged. Before this, at £20 lead, we calculated we were making profits of about £7000 a month, while each £1 rise in price would mean about an additional £1400. But we did not like to make a monthly definite statement, as the sales of lead were very slow and we did not know that all the lead was being sold. This is the reason for the form of return adopted up till now, but for the future I think we might give some estimated profit based on a given price, say £20 a ton, leaving you to calculate the additional profit if the current market price should be maintained till realization, which, I presume, is three months forward. At the present moment, when we get it, we stand to receive a large sum of money, probably £80,000 or more, and therefore we have no hesitation in declaring the final preference dividend for 1914.

Idaho's Mineral Exhibit

The Idaho mining exhibit at the Panama-Pacific Exposition is not merely a display of ores and mineral products, but a practical, comprehensive exhibit so arranged that the visitor, with the aid of the large relief model, is able to obtain a good conception of the mining geology of the entire state. The relief model stretches across one side of the exhibit space, 60 ft. long, 50 ft. high and 15 ft. deep, forming a background for the various table displays. The model presents a series of cross-sections delineating the various vein types and fault systems within the state. The table displays embrace all the various crude ores, accompanied by the inclosing wall rocks and also the mineral products. It is all arranged by counties or districts, so that one may take up the study of the ores and rocks and products of a district or a county and, with the aid of the labeling and other printed data, quickly gain a comprehensive view of mining in Idaho.

The Coeur d'Alene display is the largest, occupying a table 60 ft. long and 4 ft. deep. This presents an interesting study of the lead-silver and zinc ores, their accompanying rocks and products. Massive pieces of lead sulphide weighing 300 to 1100 lb. from the Coeur d'Alene, and also massive pieces of zinc blende from the Interstate-Callahan mine, form an interesting and attractive feature. The lead-silver, the zinc and gray copper ores from Idaho, Bonner and Boise Counties are arranged on a separate table, thus presenting these characteristic ores so distributed that they form an instructive display and enable the visitor to make acquaintance with the situation and occurrence of this character of ores. The copper display occupies a table 27 ft. long, 5½ ft. deep and contains samples of all the copper ores produced in Idaho, including malachite, azurite, black and red oxides, native copper, disseminated copper and the porphyry ores. The gold display contains ores from Lemhi and Idaho Counties and the free-milling and sulphide ores from Owyhee, Lemhi, Idaho and Blaine Counties. Included with the gold display are samples of gold in an iron mass (limonite).

MINERAL EXHIBIT OF IDAHO AT SAN FRANCISCO

The chief attraction in the structural materials division is a massive piece of sandstone, illustrating the progress from the quarried rock to the finished product, showing in the one piece the stone as originally broken out from the quarry, a portion of it roughly dressed and another part highly polished. The figure presented by the work part of the sandstone describes one-half of an arch. There is a series of photographs illustrating interesting features of Idaho mining and also the mills of the Coeur d'Alene district. Altogether Idaho has given to exposition visitors a practical, comprehensive and sane display of the mineral resources of the state.

Pig Iron Production in the Electric Furnace is carried on successfully at Tinfos, Norway. Coke is used as the reducing material and the ore carries 44 to 47% iron. The power in the furnace is from 1200 to 1400 kw. There are four furnaces at Tinfos, three being usually in operation while one is held in reserve. The output is about nine tons per furnace per day.

Solution of Pulp Problems by Graphic Methods

By W. J. McCauley*

SYNOPSIS—Proper solution and record of pulp problems are important, but are sometimes evaded on account of the time and trouble required for the somewhat abstruse calculations. Most of the problems, however, can be formulated in such manner that their solutions can be expressed in straight-line diagrams. The methods employed are explained in detail.

In many hydrometallurgical plants the importance of making accurate pulp measurements and keeping a systematic record of them is too often overlooked. The importance of such observations can hardly be underestimated, as they are essential to the proper working of any mill. The excuse for their absence usually is that no one on the job has time to look after the work, and as the mill is apparently running pretty well as it is, there seems to be no real need of keeping such records. Most mill men will admit, however, that if such information is systematically kept through several years, it is valuable and often a money maker. The trouble encountered in the taking of such measurements and the difficult nature of the subsequent calculations are sometimes causes for inattention to such details.

Customary Use of Formulas

It is the custom in most mills where such observations and measurements are taken to first determine the constants of the ore treated—the density and such others as the practice of the mill and the systems of measurement make possible. These constants are substituted in the various formulas as one of the three factors of pulp problems. The second quantity is found by measurement and the formula is solved for the third.

It is not the purpose of this article to give methods for making pulp measurements or to derive the formulas necessary for the solution of the problems. This subject has already been thoroughly discussed.

The drudgery of solving each problem every day is eliminated by solving once all the problems concerning a certain measurement which are likely to occur in practice. Tables or curves from which the desired results of any observation may be read directly are then made. Such conveniences are somewhat difficult to formulate because to have them accurate it is necessary to solve substantially every problem within the range of the table or curve. This is usually a task of no small proportions, and should one of the previously determined constant quantities become changed at any time, the labor must all be repeated.

Graphs to Facilitate Operations

With the idea in view of rendering the making of such charts simpler I have undertaken to produce a method of graphic analysis for the solution of pulp problems, and to make a system of straight-line charts which may be drawn in a few minutes and with little or no calculation.

*Mining engineer, Lemmon, S. D.

The basic principles of this system were suggested in an article published by George B. McLain in the *Mining and Scientific Press*, Aug. 3, 1912. In this article the method of making and using a straight-line chart for the determination of the percentage of solution and solids in mill pulps is explained; the density of the ore being a constant and the gravity of the pulp being known.

The equations may be divided into two general classes: First, those in which it is possible to assume one quantity as constant so that when a second is made to vary by equal increments the third will also be found to vary

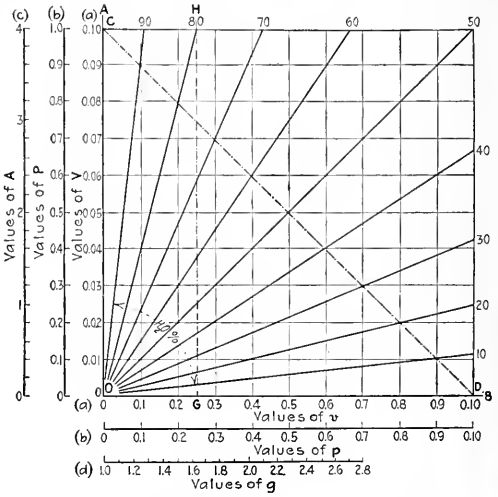

FIG. 1. CHART FOR SOLVING PULP PROBLEMS

by equal increments. Equation (1) is of this character. If in this equation either s or x is held constant it will be found that if y is varied by equal amounts, then will x or s also vary by equal amounts.

$$y = sx \qquad (1)$$

The second class consists of those equations in which the above relationship does not exist. In this case it is impossible to select any one value as constant so that if a second be varied by equal amounts the third will also vary by equal amounts. Equation (2) is of this nature.

$$y^2 = sx^2 \qquad (2)$$

The distinction between these two cases is really that of degree. The equations of the second class are formed usually not by the occurrence of the higher powers of the three variables, but by the way in which these quantities are related to one another and to the constants of the equation.

Let us now consider the nature of such equations and methods for their graphical solution, following up by some practical examples of their applications.

Formula (1) is the equation of a straight line passing through the origin, in which s is the tangent of the angle that this line makes with the axis of x. Such a problem

may be solved for all varying values of x and y, when s is a constant, by simply drawing on cross-section paper a straight line through the origin of points, which makes an angle with the axis of x whose tangent is s. A series of such lines radiating from the origin may be drawn to represent varying values of s, as in Fig. 1. All problems of this nature may now be solved by inspection of the chart.

One or two such practical pulp problems may be worked out. In explaining these charts there will be no attempt to make mathematical proofs of their correctness or the formulas used in making them.

The following symbols will be used throughout:

a = percentage of water by weight, in any pulp, expressed as a decimal.
c = a constant.
d = density of the dry pulp or ore.
g = gravity of the wet pulp.
p = number of pounds of cyanide (KCN or NaCN) per ton of solution.
P = number of pounds of cyanide per ton of solids.
R = water ratio.
t = a length of time measured in seconds.
T = tons of dry pulp discharged in 24 hr. by a pulp stream.
v = dissolved metal (Au or Ag) per ton of solution in any wet pulp.
V = Dissolved metal per ton of solids in any wet pulp.

Determination of the Dissolved Metal in Mill Tailings

The dissolved metal in discharged tailings is usually expressed as a value in cents per dry ton of pulp discharged, the value per ton of solution and the percentage of solution being known. This is accomplished by taking a sample of the tailings and determining the percentage of moisture by the gravity bottle, or other convenient method. The slime is allowed to settle from the solution and a known amount is decanted and assayed. The following formula is then employed:

$$V = \frac{av}{1 - a} \qquad (3)$$

This is of the form of equation (1). Here $s = \frac{a}{1 - a}$, and a chart, similar to the one above described, may be used.

To make this chart lay off along OB, Fig. 1, to any convenient scale, values of v, and to the same scale lay off along OA values of V. Now draw a 45° line CD and divide it into 100 equal parts. Through each of these points of division and a draw diagonal lines as shown. Number these lines from 0 to 100, starting with OB as 0 and ending with OA as 100. These numbers and the lines to which they are attached represent the varying percentages of water or solution in a pulp.

This method of drawing in the diagonal lines is evidently correct. In formula (3) let V and v be made to vary in such a manner that their sum is always a constant. The equation representing these changing values is $V + v = c$. This is the equation of a 45° line intersecting OA and OB in points other than O, such as CD. It will now be found that a varies by equal increments.

To use the chart, follow vertically up the line representing the value of v found by assay until it intersects the line representing the percentage of water previously determined. Thence follow horizontally to the left. On OA will be found the value of V sought.

In practice it is desirable to assay more than one assay ton of the decanted solution from the pulp, and it is usually desired to express V in terms of cents per ton. In this case it is better to lay off values of the actual weights of gold or silver found in milligrams along OB, and to lay off values in cents per ton along OA. Here CD will probably not be a 45° line, but will be one connecting two points, C and D, which have values such that

$$\frac{OD}{x} = \frac{OC}{y}$$

where x is the number of assay tons of the solution taken for assay, and y is the value in cents per ounce of gold or silver.

It sometimes happens that the pulp is too thick to make practicable the method just described of direct decantation and assaying of solution for the value of v. For notes on a method recommended in such cases, and the explanation of a chart for the calculations of same, the reader is referred to the *Engineering and Mining Journal* of Mar. 27, 1915.

Determination of Cyanide Loss

The cyanide loss in tailings is usually expressed as a number of pounds per ton of dry pulp discharged. The number of pounds per ton of solution is found by titration and the following formula applied:

$$\frac{ap}{1 - a} = P \qquad (4)$$

Formula (4) is of exactly the same nature as formula (3) and the same chart, Fig. 1, may be used for both.

It is often desired to know the water ratio of a pulp; that is, the number of tons of solution per ton of solids. The water ratio of any pulp is expressed by the formula:

$$R = \frac{a}{1 - a} \qquad (5)$$

Now, as has been shown, the quantity $\frac{a}{1 - a}$ has the value of s in the equation of a straight line passing through the origin. It is the tangent of the angle which the diagonal line makes with the axis of x, or in Fig. 1 with the line OB. Hence the water ratio is the tangent of the angle which the percentage water line makes with the line of zero percentage water, or OB of Fig. 1. This being the case we may lay off on OA values of R, and to the same scale lay off OG, on OB, equal to unity, and draw GH parallel to OA. Now the percentage water lines will cross GH on that horizontal line corresponding to the desired value of R.

A chart similar to the water ratio chart may be used to determine the number of cubic feet of solution per ton of dry pulp and many other similar problems.

Making Pulp-Stream Measurements

The tonnage measurement of pulp streams of nearly constant volume, such as tube-mill discharges, offers a considerable problem to the metallurgist. Such measurements are usually made by taking the time required for the stream to fill a given volume, such as one cubic foot. The following formula may then be applied:

$$T = \frac{2700\, d\, (g - 1)}{t\, (d - 1)} \qquad (6)$$

in which t is the time in seconds required to fill one cubic foot of volume.

For any ore d is a constant and hence the quantity $\frac{2700d}{d-1}$ is a constant. Once d is known for the given ore the formula becomes:

$$T = \frac{c\,(g-1)}{t} \qquad (7)$$

This equation is a rather special case of equation (1), but it can be solved by the same general methods.

Referring to Fig. 2, on OB lay off values of T to some convenient scale, starting at O as zero, and on OA lay off values of g, starting with O as the point where $g = 1$. Or, which is the same thing and practically more handy, OA may read the actual weights of the cubic-foot volume taken, starting at O with the weight of the container when full of water.

Diagonal lines, similar to those of Fig. 1, may now be drawn representing values of t, so that the horizontal line representing the value of g, or weight found, will intersect the diagonal representing the observed time of filling (t) vertically above the desired value of T.

Now if $g = 1$, T will equal zero and it follows that all the t lines intersect at O. If t is equal to zero then will T equal infinity except for the case where g is equal to unity; here T is equal to zero divided by zero which

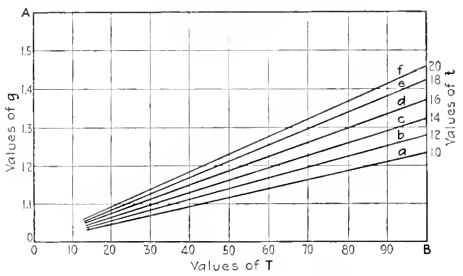

FIG. 2. CHART FOR PULP-STREAM MEASUREMENTS

is an indeterminate and may have all values from zero to infinity. Hence the line representing t equals zero and coincides with OB. If t equals infinity, then will T equal zero, and the line representing t equals infinity and coincides with OA. All other values of t are diagonals lying between OA and OB.

The t lines are all straight lines; because if t be held constant and g varied by equal increments, then will T vary by increments. If g is held constant and t is made to vary by equal amounts, then will T vary along a curve. Practically the best way to draw in the t lines is to solve the equation for each value of t liable to occur in the practice for which the chart is made, holding g constant. By this method a series of other points besides O, such as a, b, c, d, etc., on each desired t line, is found. It now only remains to draw in the t lines and number them.

In the second case the three quantities going to make up the equation bear such a relation to one another that if any one of the three quantities be held constant and a second varied by equal amounts, the third would be found to vary by unequal amounts, or along a curve. In problems of this kind it is impossible to construct a simple chart on the lines previously outlined, for we have no longer the simple equation of a straight line, but that of a curve. It may, however, be solved by a straight-line graphic method by drawing in two sets of diagonal lines, radiating from different points, so as to cross each other. These sets of lines represent two of the three values of the equation, while ordinates or abscissas represent the third. The lines representing any two of these factors meet on that point where the proper value of the third factor, necessary to balance the equation, meets them both.

There is at least one pulp problem of prime importance which falls in this class. By referring again to Fig. 1 it may be discussed.

Percentage of Water in Pulp

This problem was solved graphically in a very ingenious way by Mr. McLain. My method is similar, but in many respects the reverse of that given by McLain. My three quantities entering into this equation are a, d and g. The relationship between them is expressed by the formula:

$$a = \frac{d-g}{g\,(d-1)} \qquad (8)$$

which is evidently of the form of the second case.

On a chart constructed in accordance with Fig. 1, lay off on OB to some convenient scale, the density, d, of the ore. Let this be OF. Now on OA lay off, to the same scale, OE equal to the gravity of the solution; that is, unity as a rule. Divide OF into equal parts varying from unity at O to d at F. These divisions represent the gravities, g, of the pulps which are possible from the ore whose density is d. Draw EF. Now when g is determined by the gravity bottle or other method, the vertical line representing this value of g intersects EF at the same point as does the diagonal line representing the percentage of solution, a, sought.

This last described chart, giving the relation between a, d and g, may be made according to the method outlined only when CD is a 45° line. If the dissolved value chart be made along the line previously suggested; that is, wherein CD is not a 45° line, it is necessary that OF and OE bear a relationship different to one another than that of $OE : OF :: 1 : d$. If the chart is constructed in this manner the relationship between OF and OE will be such that

$$\frac{c}{x} = d\,\frac{1'}{y}$$

where x and y have the same values as that assigned to them in the discussion of the dissolved value chart.

In discussing the various charts a single figure has, for the most part, been used. In the actual use of this method of analysis it is better to make individual charts for each problem to be solved; thus avoiding unnecessary lines and figures.

In what has gone before I have attempted to give the outline of a method of graphic solution of pulp problems, and explain the same by giving methods for the analysis of a few of the more commonly occurring ones. The scope of this field has only been touched; but the underlying principles of the method may be applied to nearly every pulp problem, and little difficulty should be encountered in extending them beyond the scope of this paper.

By drawing such charts to large scale and exercising care in their construction, they may be made as accurate as, or even more so than, the measurements can be taken, and fully accurate enough for all practical purposes.

American Institute Meeting at San Francisco

Elaborate arrangements have been made for the meeting of the American Institute of Mining Engineers, in San Francisco, Sept. 16-18. It will be followed by a series of excursions, which will leave those members who desire to do so free to attend the International Congress at San Francisco, Sept. 20-25. A large number of papers have already been offered for this meeting.

Several other papers of value are now under consideration by the committee, and will be distributed in advance of the meeting. The technical programs have been arranged for several simultaneous sessions on September 16 and 17, in order to allow ample time for the discussion of the various subjects.

Papers to Be Presented

The papers accepted and now in the hands of the printers follow:

Mining Methods and Law—"Fire-Fighting Methods at Mountain View Mine, Butte, Mont.," C. L. Berrien; "Underground Mining Systems of Ray Consolidated Copper Co.," Lester A. Blackner; "Mining Conditions on the Witwatersrand," W. L. Honnold; "Ore Tramming and Hoisting at the Copper Queen Mine," Gerald Sherman; "Churn-Drilling Costs, Sacramento Hill," Arthur Notman; "Application of the Apex Law at Wardner, Idaho," Fred T. Greene.

Mining Geology and Mineralogy—"Formation and Distribution of Residual Iron Ores," C. L. Dake; "Occurrence of Covellite at Butte, Mont.," A. Perry Thompson; "Formation and Distribution of Bog Iron Ores," C. L. Dake; "Geology of the Burro Mountain Copper District, New Mexico," R. E. Somers; "Additional Data on Origin of Lateritic Iron Ores of Eastern Cuba," C. K. Leith and W. J. Mead; "Method of Making Mineralogical Analysis of Sand," C. W. Tomlinson.

Milling Methods—"Kick vs. Rittinger," Arthur O. Gates; "Concentrator of the Timber Butte Milling Co., Butte, Mont.," Theodore Simons; "Hardinge Mill Data," Arthur F. Taggart.

Copper—"British Columbia Copper Co.'s Smelter, Greenwood, B. C.," Frederic K. Brunton; "Hydro-Metallurgy of Copper," L. D. Ricketts, et al.; "Hydro-Electrolytic Treatment of Copper Ores," Robert Rhea Goodrich; "Roasting and Leaching Concentrator Slimes Tailings," Lawrence Addicks.

Gold and Silver—"Metallurgical Practice in the Witwatersrand District, South Africa," F. L. Bosqui; "Mill and Cyanide Plant of Chiksan Mines, Korea," Charles W. De Witt; "Electric Furnace for Gold Refining at the Alaska-Treadwell Cyanide Plant," W. P. Lass; "Cyaniding Practice of Churchill Milling Co., Wonder, Nev.," E. E. Carpenter; "Notes on Homestake Metallurgy," Allan J. Clark; "Zinc-Dust Precipitation Tests," Nathaniel Herz; "Recovery of Mercury from Amalgamation Tailing, Buffalo Mines, Cobalt," E. B. Thornhill; "Slime Agitation and Solution Replacement Methods, West End Mill, Tonopah, Nev.," Jay A. Carpenter; "Amalgamation Tests," W. J. Sharwood; "A Rule Governing Cupellation Losses," W. J. Sharwood; "Tonopah Plant of the Belmont Milling Co.," A. H. Jones.

Lead—"The Salida Smelter," F. D. Weeks; "Lead Smelting at El Paso," H. F. Easter; "Advantages of High-Lime Slags in the Smelting of Lead Ores," S. E. Bretherton; "Mellen Rod-Casting Machine," R. C. Patterson, Jr.

Miscellaneous—"Conversion Scale for Centigrade and Fahrenheit Temperatures," Hugh P. Tiemann; "Thermal Insulation of High-Temperature Equipment," Percy A. Boeck; "Radiography of Metals," Wheeler P. Davey; "Metallurgical Industries as Possible Consumers of Electric Power," Dorsey A. Lyon and Robert M. Keeney.

Petroleum and Gas—"Gasoline from 'Synthetic' Crude Oil," Walter O. Snelling; "Correlation and Geological Structure of the Alberta Oil Fields," D. B. Dowling; "Oil, Gas, and Water Content of Dakota Sand in Canada and United States," L. G. Huntley; "Sliding Royalties for Oil and Gas Wells," Roswell H. Johnson; "Possible Occurrence of Oil and Gas Fields in Washington," Charles E. Weaver.

Iron and Steel—"Duplex Process of Steel Manufacture at the Maryland Steel Works," F. F. Lines; "The Electric Furnace in the Foundry," William G. Kranz; "Some Suggestions Regarding the Determination of the Properties of Steel," A. N. Mitinsky; "Commercial Production of Sound Homogeneous Steel Ingots and Blooms," E. Gathmann.

One of the sessions of the Institute will be a joint session with the American Electrochemical Society, at which papers of mutual interest will be presented and discussed. The Committee on Arrangements for the San Francisco meeting consists of C. W. Merrill, chairman; E. H. Benjamin, F. W. Bradley, Abbott A. Hanks, H. C. Hoover and W. C. Ralston.

The list of special excursions offered to members, from which they can make their selection, is as follows:

Sept. 18, special boat trip around San Francisco Bay, and visit to Selby Smelting Works. Sept. 18, the San Francisco high-pressure fire system, and the gas and electric works. Sept. 18, Spring Valley water works. Sept. 17 and 18, gold dredging and hydroelectric development. Sept. 18 and 19, the Grass Valley mines and hydroelectric development. Sept. 17 to 19, oil fields of Coalinga. Sept. 19, Spring Valley water works reservoirs and pumping stations. Sept. 19, the delta lands of the Sacramento and San Joaquin rivers.

Greene Cananea and Greene Consolidated

The combined reports of the Greene Cananea Copper Co. and the Greene Consolidated Copper Co., Cananea, Mexico, for 1914 show that the Greene Cananea now owns 959,378 shares of the outstanding issue of 1,000,000 shares of the Greene Consolidated. The mines and works owned and controlled by the Greene Cananea produced 21,858,920 lb. of fine copper, 907,310 oz. of silver and 6055 oz. of gold, including production from purchased ores. Dividends paid by this company aggregated $972,645. The average price received for copper was 13.8382c. per lb. during the year, and the total cost of refined copper, after deducting the value of precious metals and miscellaneous revenues, was 10.724c. per lb. This cost includes depreciation charges and all shutdown and other expenses.

A consolidated statement for the two companies shows total receipts of $3,852,998, made up of copper sales,

$2,794,140; silver sales, $471,792; gold sales, $115,741; miscellaneous revenue, $243,202; inventory of copper in process, $228,123. Charged against this revenue is $3,237,206, made up of operating expenses, $2,845,964; legal and general expenses, $41,990; taxes, $49,433; depreciation for 1914, $160,071; inventory of copper in process at Dec. 31, 1913, $139,748. The net income carried to balance sheet was $615,792. During the year $23,717 was added to fixed assets for new machinery, construction, etc. The following table gives details of tonnages treated and production:

STATEMENT, GREENE CONSOLIDATED COPPER CO.

Tonnage	
Wet tons domestic ore mined	384,690
Wet tons of domestic ore treated	383,380
Wet tons foreign ore treated	28,204
Wet tons custom ore treated	6,996
Wet tons Miami concentrates treated	21,007
Total ore treated	439,587
Wet tons domestic ore milled	147,131
Wet tons foreign ore milled	263
Ratio of concentration, tons of ore milled	3646 : 1
Production	
Returnable fine copper in bullion produced from company mines, in lb.	16,169,067
Returnable fine copper in bullion produced from Miami concentrates and foreign and custom ore, in lb.	20,269,226
Silver in domestic bullion, in oz.	636,113.62
Silver in bullion from Miami and custom ores, in oz.	180,278.38
Gold in domestic bullion, in oz.	3,136.468
Gold in bullion from Miami and custom ores, in oz.	1,132.901

Recovery from domestic ores was: Copper, 2.109%; silver, 1.659 oz.; and gold, 0.0082 oz. per ton.

Of the ore 68,000 tons was mined on contract. The total cost of mining, including this ore, was $3.09 per ton. Development work aggregated 31,859 ft. at a cost of 65c. per ton of ore mined and is included in the mining cost. The total cost of smelting new copper-bearing material to the production of converter bars, f.o.b. at Cananea, was $2.678 per ton. The net cost of refined copper was 10.613c., made up of 13.635c. for gross costs less 0.1816c. for gold and silver values and 1.206 for miscellaneous revenue.

Bolivian Copper Concentration

By F. A. Sundt*

Concentration of copper ores is carried on by the Compania Corocoro de Bolivia in a 200-ton mill by a process which is comparatively simple because of the softness and docility of the ore. The ore in question is brought from the Remedios, Capilla and San Agustin mines by means of tramway and ropeway, and is delivered to an 11x18-in. Blake breaker. In this breaker the ore is reduced to 2- or 3-in. pieces and delivered to chilean mills, where it is crushed to $\frac{1}{16}$ in. There are three of these mills, each having two rollers of granite with steel tires. Each roller is 1.5 m. in diameter, while the tire is 4 in. thick and 18 in. wide. The mills make 12.5 r.p.m. and each grinds 3 tons per hour.

From the chilean mills, which grind the ore in water, the pulp is taken to an elevating wheel 9 m. in diameter. This delivers the pulp, at a higher elevation, to a vibrating screen 2x6 ft., working at 240 strokes per min. The screen material is $\frac{1}{16}$-in. ton-cap copper wire. The oversize from the screen returns to the chilean mills for further grinding, and the undersize is taken to a hydraulic classifier of the Lake Superior type. This classifier has six spigots, which feed the three Harz jigs. The jigs have each three compartments and operate at 260 strokes per min. The screens are perforated copper plates, having apertures of $\frac{1}{8}$ and $\frac{1}{16}$ in. Middlings from the jigs are taken to the chilean mills, where they are reground, while the overflow water is used for grinding fresh ores.

Concentrates from these jigs contain about 50% copper. These are reconcentrated in another Harz jig having 280 strokes per min., the final concentrate product from which contains about 85% copper. Overflow from the hydraulic classifier goes to the table classifier, a V-shaped trough-type machine which has no hydraulic water. There are five Overstrom tables which catch practically all the copper. The overflow from the table classifier goes to waste, as also do the tailings from the tables. Middlings are elevated by a Frenier pump to another Overstrom table, where a final copper product is obtained. The middlings of this table return to the Frenier pump.

Concentrates Exported

Copper in the original ore is principally in the native state and amounts to 4 or 5%. The gangue is sandstone and there is very little clay. The concentrates produced have an average of about 85% copper, while the tailings sent to the river contain only 0.3 to 0.4%, thus making an extraction of more than 90%. The concentrates are called *barrillas,* and are put into sacks containing 50 kg., and then exported. The impurities in the concentrates consist principally of sand, and they contain but little iron and no sulphur, arsenic or other impurities, a fact which is due to the clean character of the ore. When smelted, the concentrates yield a copper which is so pure as not to require electrolytic refining.

To smelt the concentrates at Corocoro or on the coast is not economical because fuel is expensive and the export tax on copper bars is, say, 100%, while for concentrates it is only 70%. Milling is comparatively high because the cost of fuel is high and the steam plant is an old one. The company contemplates the installation of a Diesel motor plant with electrical generators. Labor is cheap, varying from 1.40 to 2 bolivianos per lift. Freight charges from Corocoro to on board the vessel at Arica is 24 bolivianos per ton of concentrates. The freight from Arica to England is now 45s. per ton.

Each of the jigs consists of three compartments, each having an area of 82x45 cm. The screens are of $\frac{1}{8}$-in. copper plate with perforations $\frac{1}{8}$ and $\frac{1}{16}$ in. diameter, and they last about 120 days. The bed of the jig is self-made and is 4 in. deep. Concentrates discharge through the screen, while the middlings go to the chilean mills. The length of stroke on these jigs is 5 to 15 mm., and the number of strokes 260 to 300 per min. The hutch product of the third compartment of the jig is low grade and is returned to the same jig for reworking. Classifying for the tables is done in a classifier 4800 mm. long with six spigots. It is 720 mm. wide at the head and 540 mm. at the end and its height is 1400 mm. The angle of the bottom is 60° and the spigots are 1 in. diameter. Its capacity is 200 tons per day of 24 hr. Water for the mill is supplied by a 4-in. centrifugal pump elevating 4 m. The elevator wheel is 9 m. in diameter, has 48 buckets and revolves at 2 r.p.m., average speed.

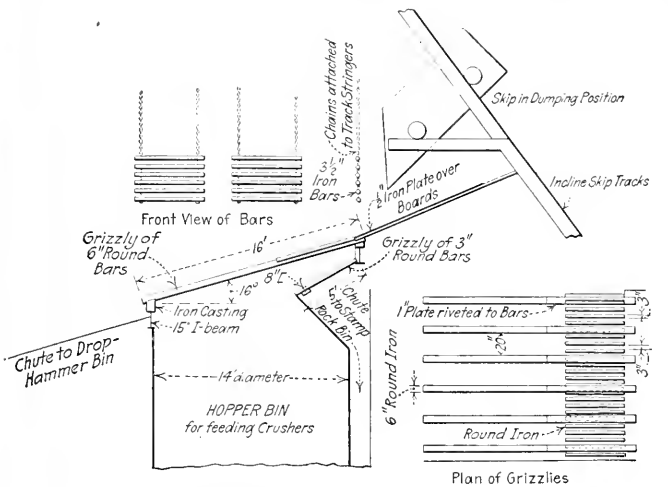
*Manager, Cia. Corocoro de Bolivia, Corocoro, Bolivia.

Details of Practical Mining

Quincy Dump and Grizzlies

By L. Hall Goodwin*

In the Lake Superior copper district it is the custom to break the rock big in the stopes; the sizes sent to the surface range up to the maximum jaw-opening of the crusher, which is generally 24x36 in., or even larger. These large boulders are reduced to about 4-in. maximum size in the rockhouse. The usual practice is to dump the contents of the skip on a heavy iron dumping plate, from which the rock passes over a single set of grizzly screens to remove 4-in. undersize before it is fed to the crusher. The Quincy mine has modified this method in several ways, the principal object being to separate the largest boulders from the rest of the rock. I outlined its practice briefly in a paper describing the rockhouse methods of the company appearing in the *Journal* June 19 and 26 and July 3 and 10, 1915. A more detailed description follows, with a sketch of the dump and grizzlies.



QUINCY DUMP AND GRIZZLIES

The rock from the dumping skip strikes a battery of 3½-in. round iron bars horizontally suspended in front of the dump from chains attached to the track stringers. There are two of these batteries, one for each skip; they serve to deflect the rock downward upon the grizzlies and to spread it evenly over them. Two sets of grizzlies are used. The first one consists of 6-in. round iron bars, 16 ft. long and inclined at 16°, having 20-in. spaces. This allows the larger boulders of copper rock and mass copper to pass over to a bin in front of the drop hammer used to break them before they are fed to the crusher, and the mass copper to be cleaned. The second grizzly set below consists of 3-in. round iron bars, 5 ft. long, inclined at 30°, having 3-in. spaces. The undersize which goes through this grizzly passes directly to the stamp-rock bin; the oversize passes to the hopper bin in front of the crushers. The dump and grizzlies are located high above the crusher floor, as they must be above the hopper bin. They are sided by iron plates 3 ft. high and above this is sheet iron to prevent flying rocks from injuring the men on the crusher floor.

The Advantage of Tamping

Exhaustive tests by the Bureau of Mines as to the efficacy of stemming on the effect of explosives have proved conclusively that confinement of the charge in the hole by the use of some inert substance on top increases its efficiency to a marked degree. The Bureau chooses to use the word "stemming" in place of the term "tamping," so commonly used, to differentiate the latter from the name of the operation of placing the stemming. In other words the Bureau favors the adoption of tamping the stemming in the hole. There is always a certain amount of opposition among miners to tamping a hole and some very prominent mining engineers question the advisability of so doing. It is probable, however, that the data on which they formed these conclusions were not carefully and exhaustively drawn.

Tamping a hole has the same effect as putting a wad in a shot-gun shell or inserting the bullet in a rifle cartridge and is easily determined. For instance, take two ordinary rifle cartridges and crowd the bullet $\frac{1}{16}$ in. nearer the base in one than in the other. Then fire the two. The "kick" against the shoulder will readily demonstrate the appreciable difference between the loose and the tight tamping of the powder charge. The same thing happens on a much larger scale when confining the explosive in a drill hole, and the kick of the explosive against the rock to be broken is much increased by close tamping in the throat of the hole.

Safety First in Reloading a Hole

It is not uncommon practice among miners who return soon after a blast to the heading to see the result of their round, and who find a hole which has not broken properly, to reload immediately and shoot it over. This is dangerous practice unless the hole is filled with water and thoroughly cooled, or unless a sufficient time is allowed

to elapse in order to effect the same cooling by air. Instances have been known where a miner loading a hole with gelatin without observing these precautions was blown to atoms through the ignition of the explosive by the heat remaining in the rock.

Mine Messhouse Operation

The mine messhouse is a troublesome adjunct to a mining operation. It is rarely given the attention it deserves, and except for providing good food it is left to take care of itself. Accurate data and details of messhouse operation are therefore of value.

The Arrowrock dam was constructed in Idaho by the United States Reclamation Service under conditions sufficiently resembling mining operations to make the figures for messhouse operations, published in *Engineering News*, June 24, worth while for the mining engineer.

A sufficient charge is made against messhouse operations each month for rental to absorb the cost of messhouse building during the time of construction. A monthly charge is also made to cover depreciation of equipment.

It is very necessary that a careful record of cost be kept and reports prepared each month to show the results accomplished. The principal items of cost should be classified, so that they may be compared from month to month. The following cost-accounts have been used in connection with the messhouse operations at Arrowrock: Labor, cooks and helpers; labor, miscellaneous; subsistence; supplies; utensils; rental; fuel; lights; depreciation of equipment; general and overhead expense.

After the mess has been operated for a sufficient length of time certain standards of cost will be established, and effort can then be made by watching the cost reports to maintain these standards.

From data kept under this classification it is possible to prepare at the end of the month cost reports in the following form:

FIELD REPORT OF MESSHOUSE OPERATIONS AT MAIN MESS, ARROWROCK, SEPTEMBER, 1914

Debits		Account Nos. 730 to 739	Credits	
Inventory			Collections:	
Subsistence	$533 46		Cash	$135 40
Supplies	26 22		Coupons	96.00
Utensils	1500 00	$2,059 68	Meal tickets	$231 40
Received during month:			Deducted on timebooks:	
Subsistence	8134 89		Arrowrock	10,479 25
Supplies	344 71		B. & A. Ry.	598 50 11,077 75
Utensils	35 52	8,515 12		
Labor:				
Cooks and helpers	1559 10		Deductions on disability claims	12 75 12 75
Miscellaneous	21 50	1,580 60		
Miscellaneous expenses:			Miscellaneous credits	
Rental	169 00		Meals served to hospital patients	173 80 173 80
Fuel	247 50			
Lights	15 00			
Depreciation on equipment	50 00	472 50		
			Inventory:	
			Subsistence	788 49
			Supplies	26 15
			Utensils	1,350 00 2,164 64
Profit		1,032 44	Total	13,660 34
Total		13,660 34		
Total cost for month		$10,463 26	Total number men, days	16,249
Total number of meals furnished		48,718	Unit cost per man, day	$) 644
Unit cost per meal		$) 215	Labor cost per man, day	097
Pounds of meat used		21,171	Supplies cost per man, day	021
Pounds meat used per man, day		1 3	Misc. exp. cost per man, day	041
			Gen. exp. cost per man, day	060
			Subsistence cost per man, day	.485

This is on a scale much larger than that appertaining to the usual mine boarding house, so that the cost per man per day of 48.5c. is much lower than the average cost at a mine where the usual charge is $1 per man per day and where the manager is reasonably satisfied if his boarding house breaks even at the end of a year.

Another innovation at a messhouse of this kind was in the use of small tables and serving food in family style—that is, all food is on the table at the time the meal is called. At Arrowrock small tables accommodating eight persons are provided, as this number may be served from one set of dish-ups. With this method one waiter can attend to five tables of eight persons each in an efficient manner. These small tables have been found to be a decided improvement over the long tables commonly used in construction camps.

Sinking Shoe for Soft Ground*

The sinking shoe shown in Fig. 1 was recently used in sinking a shaft in soft ground on the Mesabi Range. In operation, the dirt along the shoe was removed from the inside and the shoe jacked down until sufficient room had been gained for a set of timbers. While this shoe set was a success, it was evident that its design could be improved. As the shoe set was made of the same size as the shaft set, the ground excavated did not give the space required for the lagging. The open space between the shoe set and the last shaft set was unsupported, and to hold the ground it was necessary to drive short spiling. The corner construction was weak, and the wall plates of the set tended to turn over under the pressure from the jacks.

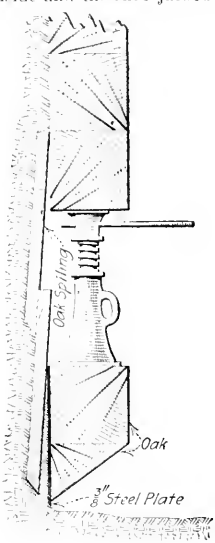

FIG. 1. SECTION THROUGH OLD SHOE

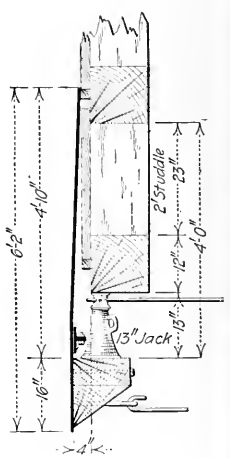

FIG. 2. SECTION THROUGH NEW SHOE

To remedy these defects, an improved sinking shoe was designed, as shown in Figs. 2 and 3. The method of operation is the same, but the set is much heavier; the corner construction has been strengthened; tight rods at

*"The Wisconsin Engineer," April, 1915.

the end correct the tendency to overturn under the jack pressure, and the shoe is 4 in. larger all around than the regulation set, which gives plenty of room for putting in the lagging or lath. Attached to the cutting plate are

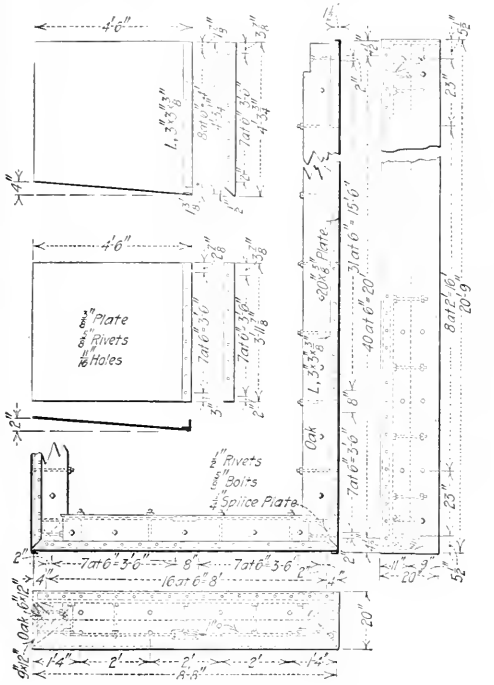

FIG. 3. DETAILS OF NEW STEEL SINKING SHOE

side plates of ⅜-in. steel, long enough to permit installing a full set of timbers with 2-ft. studdles.

This shoe gave perfect satisfaction under the conditions for which it was designed.

Jackhamer Drifting

At the Colby iron mine, Bessemer, Mich., drifting is done by use of Jackhamer auger machines, using two men for one machine. These two men do only the drilling and are followed by a blasting gang and a tramming gang for each drift of the six different headings where this system is used. The size of the drift outside of timber is 8x9 ft. During the period in question 2547 ft. of drifting was accomplished in 112 shifts, which is equivalent to 11.3 ft. per man per shift. The costs per foot are as follows:

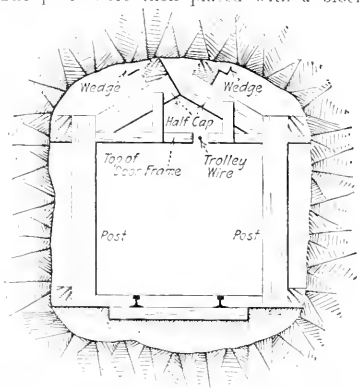
LABOR		
Miners	$0.412	
Trammers	.990	
Timbermen	.360	
Trackmen	.121	
Blasters	.116	
		$1.999
SUPPLIES		
Lagging	$0.094	
Timber	.210	
Explosives	.330	
Light, steel, shop labor, etc.	.060	
		.694
Total		$2.693

The foregoing figures include cost of breaking the ore, tramming it to the chute, timbering the drift, laying track and necessary supplies for the same except the cost of rails.

Timbering for Air-Check Doors in a Motor-Haulage Drift

By Frank S. Crawford*

In the Calumet & Arizona Mining Co.'s mines there are places where the natural air current is so strong that it was decided to place air-check doors to direct the air current into some of the hot, badly ventilated stopes. One of these doors was placed in a motor drift. The frame of the door had to be made so as to allow free passage for the trolley and the trolley wire. To accomplish this the top of the frame was made in two pieces. The posts had to be blocked out securely against the ground, and as it was not desirable to put in an extra cap above, with the necessity of longer posts and the taking down of more ground, the problem was solved by taking two pieces of square timber cut with a bevel on the ends to fit against the tops of the posts and form an arch. The bevel on the ends joining each other was such as to leave a small opening, a couple of inches, on the upper side. The posts were then placed with a block behind



TIMBER SET PLACED FOR AIR-CHECK DOOR

each to hold them in place out from the ground. The two pieces were then set in place and wedges and blocking driven in above to force them down from the roof, causing the gap to close between the ends and forcing the posts tightly against the ground.

These spreaders served to support the top of the door frame rigidly and allowed space for the trolley wire to play up and down.

A "consin-jack" miner ran it and said, "Blawst me, it looks like a bloomin' 'ouse."

Mine Accidents in Arizona

During the year ended Dec. 1, 1914, there were, according to the 1914 annual report of the State Mine Inspector, 62 fatal accidents at the Arizona mines, which is at the rate of 6.6 fatal accidents per 1000 men employed. There were 758 serious and minor accidents, which is at the rate of 80.6 per 1000 men employed.

*Lowell Station, Bisbee, Ariz.

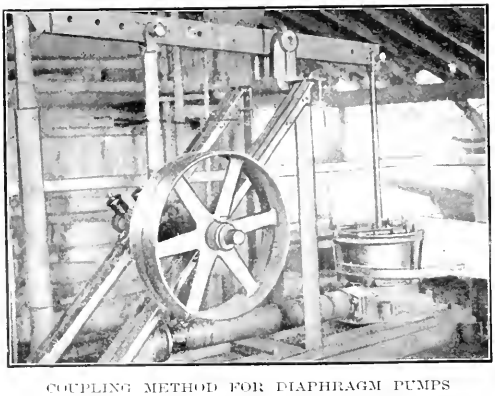
Details of Milling and Smelting

Diaphragm Pumps for Slimes

By Jesse Simmons*

With the adoption of Dorr thickeners and the counter-current system of continuous decantation, mill superintendents were forced to accomplish the economical handling of slimes. At first air lifts were almost universally used. Some installations of centrifugal pumps were made, but most operators now install diaphragm pumps. The chief objection to these pumps seems to be that the manufacturers have not studied the application of their goods to the uses to which they are now put and invariably send out a pump with the drive and gearing close-coupled. Spattering slimes cause excessive wear on the gears and pinions, necessitating large repair bills and entailing a consequent loss of service.

Of many means of overcoming this difficulty, the illustration, which shows the type of drive developed at



COUPLING METHOD FOR DIAPHRAGM PUMPS

the Golden Reward mill, at Deadwood, S. D., is one of the most noteworthy. The frame is made of light angle-iron and I-beams, with a jackshaft at one end about 5 ft. from the pump and far enough away to escape the spatterings of slimes. This shaft is belt-driven. Attached to it is an eccentric which drives a walking-beam that operates the pump. The whole mechanism rests on a bed composed of a rectangular frame of 1x6-in. timbers.

*Mining engineer, Deadwood, S. D.

Potassium Permanganate as a Cyanicide

In some recent tests made on the action of potassium permanganate as a cyanicide (abstracted by the *Journal* of the Society of Chemical Industry from the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa) normal solution from a sand-filling plant, containing 0.0013% of potassium cyanide and 0.0015% of potassium sulphocyanide, was treated, as were also solutions of sodium cyanide (strength equivalent to 0.2% of potassium cyanide), sodium thiocyanate of the same strength, and sodium-zinc cyanide of the same strength. The first three solutions were considerably affected by the permanganate, but the reaction was still incomplete after four days. Sodium-zinc cyanide, which is present in large proportions in working solution, appeared to be only slightly, if at all, affected by the permanganate after four days' contact.

Vogt Process of Recovering Rare Elements

A new process which relates to the recovery of rare elements, particularly radium, uranium and vanadium, from ores such as carnotite ore, is that invented by Louis F. Vogt (U. S. pat. 1,129,029). In following out this process the ore is first concentrated according to any approved manner, or if of a suitable character it may be merely ground. The ground ore is then roasted in the presence of salt and steam, the latter being employed for oxidizing purposes. It is then leached with water to remove the greater part of the vanadium content. A small amount of sodium carbonate is added to the water to convert any possible radium or barium chloride to the carbonate form and prevent the formation of radium or barium in soluble form in the sodium-vanadate solution.

The remaining ore from this leaching treatment is then leached with some acid, principally sulphuric, to recover the uranium and such vanadium as may remain. If other than sulphuric acid is used, sufficient sulphuric acid must be added to form an insoluble radium sulphate, and thus prevent the radium content of the ore from going into the solution. At this stage the remaining solids contain insoluble radium and barium salts and the liquor contains uranium and vanadium salts and impurities in solution.

The liquor is neutralized with sufficient sodium carbonate to precipitate such impurities as iron, alumina, silica, etc., together with most of the uranium and vanadium. If the solution contains impurities in sufficiently large quantity, all of the uranium and vanadium content will be precipitated.

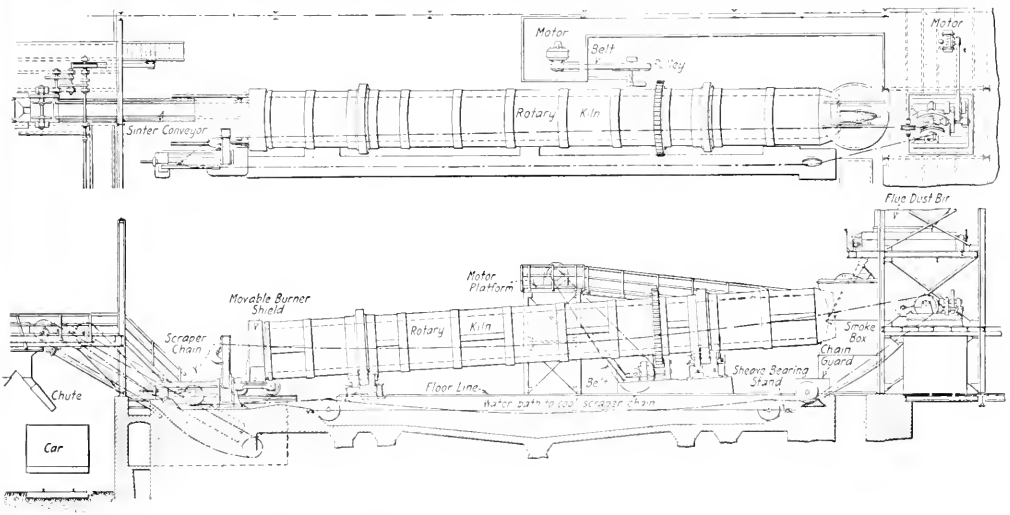
To the solution and precipitate resulting from the neutralizing step an excess of sodium carbonate is added and the mixture boiled, to leach out the uranium and vanadium contained in precipitate, leaving only the impurities. The solution is separated by filtering and is treated to recover the uranium and vanadium. Boiling with a lead salt forms lead vanadate, and the remaining solution is boiled with sufficient sodium hydrate to completely precipitate uranium as sodium uranate.

The solid ore residue is then washed, filtered, dried, mixed with sodium carbonate and fused. The resulting matte, containing carbonate of radium, barium, iron, lime, etc., is treated with water and agitated, taking out the soluble carbonates and leaving the insoluble ones. After filtering, the insoluble carbonates are washed with

water to remove any remaining sodium silicate and free alkali. The carbonate mixture is then treated with a mineral acid, preferably hydrochloric, to dissolve the carbonates, and then by adding sulphuric acid, radium and barium sulphates are precipitated. The dried sulphates of radium and barium are thoroughly mixed with fine coke and a suitable chloride and roasted. The roasted mixture is leached to dissolve the chloride, leaving radium and barium chloride in the solution. Uranium is separated from the barium and impurities by systematic fractional crystallization.

New Sintering Plant at Gary

The new plant for sintering flue dust at Gary, Ind., has a capacity to treat the dust from 12 iron blast furnaces. At present, however, there are only eight stacks at Gary. The sintering plant now comprises two rotary inclined kilns, 90 ft. long by 9 ft. in diameter, a 12-in. brick lining



PLAN AND SECTIONAL ELEVATION OF GARY SINTERING PLANT

reducing the effective inside diameter of the kiln to 7 ft. The accompanying drawing, reproduced from *Iron Age* of May 27, 1915, shows one of the sintering kilns in plan and cross-section. The steel shell is made of $\frac{11}{16}$-in. plate with butt seams, quadruple-riveted. Each kiln is fitted with two annular bearing rings and mounted on idler rollers. The kiln is rotated at about 1 r.p.m. by means of an annular gear near the upper bearing ring, power being supplied from a 60-hp. motor placed on an overhead platform. The motor runs at 715 r.p.m., but this speed is reduced by means of a belt-drive and bevel gears which drive the pinion that engages the annular gear on the kiln.

At the lower end of the kiln is a movable burner shield, mounted on trucks so that it may be drawn back from the mouth of the kiln when not in service. The kiln will be gas-fired, gas being obtained from the nearby coke ovens of the Gary plant.

An interesting feature of the kilns is the drag-scraper chain which passes through the kiln from end to end, returning below the kiln through a bosh, for cooling. The chain has an approximate speed of 70 ft. per min., and is expected to loosen material which may stick or hang in the kiln, keep it moving toward the discharge end and thus prevent the formation of accretions within the kiln.

The flue-dust is frequently handled, owing evidently to the necessity for storage. It is brought to the plant in hopper-bottom cars, and deposited into steel-and-concrete track hoppers. From these hoppers the dust is fed by screw conveyors to a bucket elevator, which carries it up to the overhead hopper at the end of the kiln house. The dust then passes by gravity to a revolving screen having 1-in. mesh and into either of two 230-ton cylindrical bins. From these steel storage bins, another motor-driven screw conveyor feeds the dust directly into the kiln, the speed of the conveyor being under close control.

The flue dust works its way down through the kiln toward the firing end and encounters the zone of greatest heat a short distance in front of the discharge end. The sinter drops through a floor-grating on an inclined conveyor, which elevates it into hoppers immediately above the loading track. Each hopper has two delivery spouts so that the sinter may be discharged into cars on two tracks. Sprays are provided for cooling the sinter as it drops into the cars.

Making Arsenic Compounds

A process for making arsenic acid has been patented by George P. Fuller, of Niagara Falls, assigned to the National Electrolytic Co. This consists of subjecting a suspension of arsenious oxide in an aqueous solution of an alkali-metal halide to electrolysis. The anode must be insoluble and therefore platinum is usually employed. The cathode is best made of copper, although cathodes of other metals may be employed. Since the ordinary form in which arsenic is employed in the arts is as sodium arsenate, it is best to make the alkaline halide a sodium-chloride solution; otherwise the final removal of the arsenic salt will be impracticable, owing to the difficulty of separating sodium from any other base.

The Cost of Doing Things

Drilling Costs in Potash Prospecting

By E. E. Free*

During the summers of 1912, 1913 and 1914 the Railroad Valley Co. of Tonopah, Nev., carried out an extensive prospecting campaign for potash deposits in various parts of the Great Basin and especially in Railroad Valley, Nye County, Nevada. In that vicinity the existence of a buried saline body was suspected, and the prospecting took the form of drill holes designed to reach and explore the supposed saline horizon. Five of these holes were located on the mud flat or *playa* left by the ancient lake which once occupied the valley, and these five holes were sufficiently alike in materials penetrated and in general conditions to be possible of discussion together. Although the general conditions surrounding the work were somewhat unusual, it is possible that the cost data of the accompanying table may have some general interest. The prospecting proved negative, so far as potash is concerned, and has been discontinued.

The work here reported was done between June 20 and Nov. 10, 1913, but during this period there were two shutdowns aggregating 45 days, leaving a total of 99 days' actual work. Field operations were in charge of D. H. Walker, superintendent of the Railroad Valley Co.

Railroad Valley is southeast of the center of Nevada in a sparsely settled desert country without towns, railroads or other facilities. All supplies for the work were hauled by wagon or auto truck from Tonopah, 120 miles west, or from Ely, 75 miles northeast. Drilling was by the rotary jetting method, using an American Well Works rotary attached to a steam-driven Keystone portable rig No. 5. Water circulation was maintained by two American Well Works steam pumps supplied by a separate boiler. The entire outfit was already in the possession of the company and cost approximately $7000, including drill rod, all tools and general equipment, also camp equipment consisting of four tents, boarding house, office, wagons, water tank, etc. No depreciation or interest on this equipment has been included in the costs given. The holes were 5½ in. in diameter and were not cased except for 20 to 50 ft. at the top.

The materials penetrated were essentially the same in all five holes. The upper portions were in smooth clays with little or no sand. The hardness was somewhat variable and a few cemented layers were encountered, but never of such induration as to create serious obstacles to drilling. In their lower portions holes No. 2 and No. 6 encountered beds of solid, crystalline gaylussite[1] alternating with beds of clay. The crystalline material was fairly hard and drilled like soft sandstone or shale. Similar beds were encountered but not entered by hole No. 4. The thicknesses of the beds penetrated by the individual holes are given in the table.

*Chemical engineer, 1105 Madison Ave., Baltimore, Md.

[1]The mineral gaylussite is the hydrous double carbonate of sodium and calcium ($Na_2CO_3 CaCO_3 5H_2O$). It is a member of the saline series for which search was being made. For details concerning the occurrence see Free, "Min. and Sci. Press," Aug. 2, 1913.

culty. No water was available at or near the drill sites and preliminary 100-ft. holes had proven dry. When a preliminary 250-ft. hole (sunk with hauled water) at the site of hole No. 2 also proved dry, it was decided to bring water by ditch from an artesian well seven miles north. Water supplied by this ditch was used for all subsequent holes. In the table the item of water-supply for hole No. 2 includes the cost of the main ditch and of all preliminary work. For the other holes only the cost of ditch maintenance and of necessary extensions is included. The cost for hole No. 3 is high because the extension of the ditch to it had to be carried through a sand ridge nearly a half-mile wide and several feet high.

The item of drilling includes the actual cost of drilling only. The usual crew was: One driller, one helper, one fireman and one sampler. Occasionally two helpers were needed. Usually there were two drilling shifts of ten hours each, the firemen working three 8-hr. shifts and looking to the pumps during the 4-hr. shutdown. For a part of hole No. 2 three 8-hr. drilling shifts were used. In addition, one or two men were employed on repairs and general mechanical work and one to three teamsters were hauling drinking water and supplies and keeping the ditch in order. The wage scale was $6.50 to $5 for drillers and $5 and $4.50 for helpers, fireman and teamsters, all on the basis of an 8-hr. day with pay for overtime at the same rate. Lodging in tents was furnished free. The boarding house was run by the company and a charge of $1 per day was made for board. The deficit on the boarding house appears under general expense in the table. Teams were hired at $7 per day for team and driver and $5 per day for extra teams, not found. Fuel was wood, no other being available at reasonable cost. It consisted largely of scrub pine and juniper, and was cut and delivered by contract at from $10.50 to $12 per cord.

General expense includes all items which extended over the whole work and cannot be assigned with accuracy to the different holes. These items have been totaled and the total divided between the holes on the basis of the working time for each hole. The item for communications includes the maintenance of the company's automobiles and the hire of other automobiles when necessary. The employer's liability insurance is that required by the law of Nevada. The item for chemical work covers the cost of an accurate chemical control of the drilling, this being necessitated by the object of the work. It includes the salary of a chemist at $7 per day and the expense of the field laboratory. The laboratory equipment was borrowed from the general laboratory of the company and is not charged for. It would have cost about $300 to duplicate it.

*

Smelting Costs at Greenwood, B. C.

In connection with a description of the smelting plant of the British Columbia Copper Co., at Greenwood, B. C., Frederic K. Brunton, who was assistant superintendent prior to the shutdown in 1914, gives[1] some operating costs at this plant which smelted the lowest-grade copper ore of all American works. The plant comprises three blast furnaces—two 51x360 in. at the tuyeres and the other 51x240 in.—and two converting stands using 84x126-in. acid-lined shells. The furnaces smelted daily about 2250 tons (6.62 tons per sq.ft. of hearth area) of ore carrying 0.85% Cu; the coke used varies between 12 and 14% of the charge.

In a month when three furnaces were running and the average smelted daily in the plant was 2224.2 tons, the following operating costs were attained—these do not include overhead, depreciation nor insurance:

COSTS PER TON OF ORE SMELTED TO MATTE*

Coke	$0.851
Flux	.114
Labor	.15
Power	.033
Supplies	.03
	$1.178

Cost of coke per ton f.o.b. works bins	$6.00
Cost of flux per ton f.o.b. works bins	2.75
Cost of power per kilowatt-hour	.0065

*The furnaces were slowed up with an excess of silica on the charge because of shortage of ore, smelting only 6.55 tons per sq.ft. of hearth area as against 6.66 tons per sq.ft. when the cost of smelting was $1.084.

The working costs for turning a ton of ore into blister copper during this month amounted to $1.23. There was an average of 125 men employed and the tons handled per man-day amounted to 17.8. The cost and distribution of labor throughout the plant are shown below. The payroll amounted to $12,496 for the month in question.

LABOR COSTS AT GREENWOOD PLANT

	Labor Cost per Ton of Ore Handled
Sample mill	$ 0.00462
Bins	.01060
Briquette mill*	.00546
Furnaces	.0958
Slag disposal	.0206
Converters	.0147
Linings	.0078
Crane	.00403
Water system	.00326
General surface	.00624
Power house	.00850
Total	$0.18161

*The briquette mill made 398 tons of briquettes at a labor cost of $0.945 per ton.

Converting at this plant cost $9.60 per ton of copper produced, or $0.0048 per lb. The converters were run on two shifts only.

*

Smeltery Brick-Laying Costs

The following interesting figures on the cost of laying brick were obtained from a large amount of construction work at a Salt Lake Valley smeltery:

Buildings. Based on bag-house construction:

Cost of brick per 1000	$5.75
Cost of lime per 1000 brick @ 18c. per bu	0.335
Cost of sand per 1000 brick @ 65c. per yd	0.193
Wages of masons per 1000 brick @ $5 per day	3.205
Wages of helpers per 1000 brick @ $1.75 and $2.25	1.530
Total cost per 1000 brick	$11.013

Average brick laid per 8-hr. day per mason, 1560.2
Average number of helpers per mason, 1.285

Foundations. Based on H. & H. pot foundations:

Cost of brick per 1000	$5.75
Cost of cement per 1000 brick @ $1.64c. per sack	6.625
Cost of sand per 1000 brick @ 65c. per yd	0.495
Wages of masons per 1000 brick @ $5 per day	5.164
Wages of helpers per 1000 brick @ $1.75 and $2.25	3.184
Total cost per 1000 brick	$21.218

Average brick laid per 8-hr. day per mason, 968.3
Average number helpers per mason, 1.877

Flue Construction, over forms. Based on section of Fogh catenary flue 21-ft. base:

Cost of brick per 1000	$5.75
Cost of lime per 1000 brick @ 18c. per bu	0.35
Cost of sand per 1000 brick @ 65c. per yd	0.21
Wages of masons per 1000 @ $5 per day	7.353
Wages of helpers per 1000 @ $1.75 and $2.25	6.327
Total cost per 1000 brick	$19.99

The above includes bricklaying, tending and materials only. It does not cover freight, unloading, forms, etc.

It consists, as usual, of a general review of the technical and financial conditions underlying the fertilizer trade, followed by a complete guide to buyers and sellers of all classes of material used in the fertilizer industry.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALKALI COMPOUNDS—Process of Obtaining Alkali Compounds Useful for Fertilizing. Thomas L. Willson and Maximilian Mattheus Haff, Ottawa, Ont., Canada, assignors, by direct and mesne assignments, to Southern Investment Co. of Canada, Ltd., Montreal, Canada. (U. S. No. 1,144,405; June 29, 1915.)

ALLOY-COATING PROCESS. Jay C. Beneker, Cincinnati, Ohio. (U. S. No. 1,144,524; June 29, 1915.)

CLASSIFYING—Process of and Apparatus for Sizing or Classifying Comminuted Materials. Henry M. Sutton, Walter L. Steele and Edwin G. Steele, Dallas, Tex. (U. S. No. 1,141,852; June 1, 1915.)

CONCENTRATOR—Pan-Motion Concentrator. Charles H. Muhleman, Western Springs, Ill., assignor of fifty-five-one-hundredths to Frank Low, St. Louis, Mo. (U. S. No. 1,141,972; June 8, 1915.)

CRUSHING—Ore Grinder. Edward F. McCool, Victor, Colo. (U. S. No. 1,144,305; June 22, 1915.)

ELECTROLYTIC APPARATUS. William E. Greenawalt, Denver, Colo. (U. S. No. 1,144,538; June 29, 1915.)

FILTER. William Poole Lass, Treadwell, Alaska. (U. S. No. 1,144,854; June 29, 1915.)

FLOTATION—Ore-Concentrating Apparatus. John M. Callow, Salt Lake City, Utah, assignor, by mesne assignments, to Metals Recovery Co. (U. S. No. 1,141,377; June 1, 1915.)

JIGGING APPARATUS. James W. Neill, Pasadena, Calif. (U. S. No. 1,144,494; June 29, 1915.)

LAMP—Miner's Acetylene-Gas Lamp. Justus A. Gustafson, Idaho Springs, Colo. (U. S. No. 1,142,699; June 8, 1915.)

MAGNETIC-SEPARATING APPARATUS. Edward H. Rothert, Leavenworth, Wash. (U. S. No. 1,144,383; June 29, 1915.)

METAL-COATING PROCESS. Jay C. Beneker, Cincinnati, Ohio. (U. S. No. 1,144,523; June 29, 1915.)

PULVERIZER. Frederick R. Cornwall, St. Louis, Mo., assignor to Williams Patent Crusher & Pulverizer Co., St. Louis, Mo. (U. S. No. 1,144,352; June 29, 1915.)

PURE IRON—Method of Producing Practically Pure Iron. Arthur P. Scott, Brackenridge, Penn., assignor to Allegheny Steel Co., Pittsburgh, Penn. (U. S. No. 1,144,256; June 22, 1915.)

SCREEN—Pulsating Screen. Edgar B. Symons, Milwaukee, Wis. (U. S. No. 1,141,153; June 1, 1915.)

SCREENING CONVEYOR. Thomas F. Webster, Sewickley, Penn., assignor to Link-Belt Co., Chicago, Ill. (U. S. No. 1,142,648; June 8, 1915.)

SEPARATOR—Magnetic Ore Separator. Sven Ragnar Salwén, Grangesberg, Sweden, assignor to American Grondal Co., New York, N. Y. (U. S. No. 1,141,833; June 1, 1915.)

STAMP MILL. Norman Taylor Harrington, Lansing, Mich. (U. S. No. 1,144,126; June 22, 1915.)

STEEL—Process for the Treatment of Steel. Federico Giolitti, Turin, Italy, assignor to Società Anonima Italiana Gio. Ansaldo & C., Genoa, Italy. (U. S. No. 1,144,034; June 22, 1915.)

SULPHIDE ORES—Process for Treating Complex Sulphide Ores. George E. Kingsley, Spokane, Wash. (U. S. No. 1,144,480; June 29, 1915.)

Gold Production in Australia

Official returns of gold production in the Commonwealth of Australia, in fine ounces, for the four months ended Apr. 30, Tasmania being estimated, were as follows:

	1914	1915
Western Australia	406,954	421,951
Victoria	133,425	104,601
Queensland	70,012	76,635
New South Wales	44,250	52,985
Tasmania	10,000	8,500
South Australia	2,500	2,000
Total	667,141	666,672
Total value	$13,789,804	$13,780,110

For the first time in several years the Australian production has held its own. In the period covered by the tabulation the decrease was only 469 oz., or $9694, being only 0.07%. The results in the different states, however, show considerable variation, the gains in Western Australia, Queensland and New South Wales being balanced by decreases in Victoria and in the other states. New Zealand has not reported monthly production this year, so that the official returns are confined to the Commonwealth.

Power Plant of Granby Mining & Smelting Co.

SYNOPSIS—An 800-kw. plant furnishing light, heat and power for the Granby Mining & Smelting Co.'s new zinc-smelting and acid works at Rose Lake, near East St. Louis, Ill.

About two years ago the Granby Mining & Smelting Co. built a large plant at Rose Lake, in East St. Louis, Ill., designed for the manufacture of spelter and acid. In the various processes of manufacture large quantities of steam will be required. Producer gas is to be used for smelting and calcining, and in the making of acid there will be large demand for water. The pumps and various other machines around the works are electrically driven, and current will be furnished from a central power plant. Direct and indirect heating for the various buildings, pottery rooms, etc., and the feed-water heater will take all of the exhaust steam, summer and winter. It is the intention to start manufacturing at an early date, and even now the power plant is running under a light load created by the preparations under way.

A general view of the works is shown in Fig. 1. The power plant appears at the center of the picture. The interior plan dimensions are 89x98 ft. and the height from the floor to the roof trusses, 31 ft. The structure rests on massive concrete foundations designed to bear only two tons per square foot, owing to the presence of quicksand.

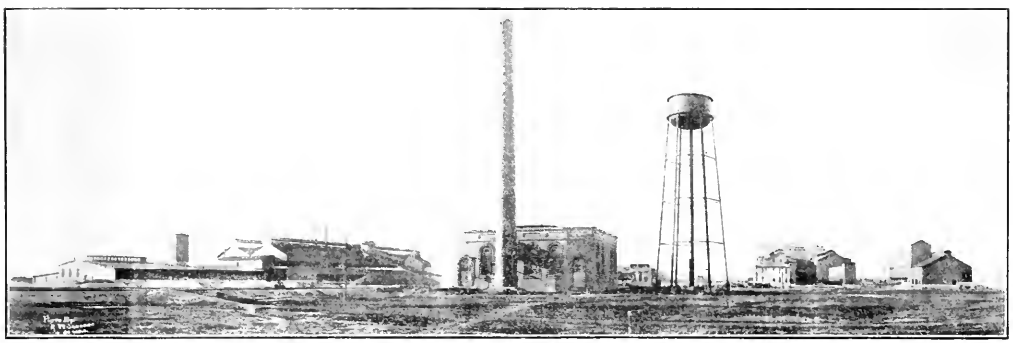

FIG. 1. GENERAL VIEW OF THE GRANBY PLANT AT ROSE LAKE, NEAR EAST ST. LOUIS, ILL.

Liberal Boiler Installation

In the boiler room, shown in Fig. 2, the equipment consists of 1050 hp. in boilers divided into three 350-hp. units of the horizontal water-tube type. The settings are of the marine type, consisting of fire-brick, 3-in. asbestos blocks and a steel-plate covering. Steam at 150-lb. pressure is supplied to 800 kw. in generating capacity, an air compressor and the feed pumps, besides some required in the manufacturing processes. The uses for steam outside of generating electricity and the installation of a spare boiler account for the excess of boiler over generating capacity. The actual ratio is 1050 to 800, or 1.3 boiler horsepower per kilowatt.

Chain-grate stokers having an area of 70 sq.ft. serve the boilers. When compared to the 3500 sq.ft. of heating surface the ratio is standard at 50 to 1. The boilers are vertically baffled for three passes, and between the furnace and the first pass a restricted throat insures the thorough mixture of the gases so necessary for smokeless operation.

Details of Flue Design

The stack rises 185 ft. above the grates, the diameter is 8 ft. and the sectional area of the bore is a trifle more than 50 sq.ft. The ratio of stack to breeching area is thus 10 to 13, or 1 to 1.3. For every square foot of connected grate surface, there is 0.31 sq.ft. of breeching and 0.24 sq.ft. of stack. Per 1000 sq.ft. of boiler-heating surface the areas of breeching and stack are 6.2 and 4.7 sq.ft. respectively. A stack draft of 1.1 in. with a gas temperature of 500 deg. reduces to 0.8 in. at the breeching side of the damper on the boiler farthest from the stack. A drop of 45 to 50 per cent. through the damper and boiler setting gives a draft of approximately 0.4 in. over the fire.

Treating Boiler-Feed Water

Water for boiler feeding is taken from wells on the premises and is high in scale-forming matter. A hot-process system for treating it chemically before passing it along to the boilers was installed.

ANALYSIS OF WELL WATER

Chemical Impurities	Grains per U. S. Gal.
Suspended matter	1.00
Organic and volatile	2.12
Silica	1.45
Calcium carbonate	13.75
Magnesium carbonate	4.04
Magnesium sulphate	0.88
Sodium sulphate	0.35
Sodium chloride	0.29
Total solids	24.18

The apparatus in use at this plant is of the vertical type shown in Fig. 3. While the various parts going to make up the complete outfit are more or less standard, their arrangement and the combinations employed differ for each plant, so that a description of the present system

*Abstract of an article by Thomas Wilson in "Power," July 6, 1915.

may be of interest. The raw water from the service supply enters the heating section, shown at the top, through a balanced regulating valve operated by a float in the float box, which maintains a uniform level in the storage chambers above the filters. Within the heating chamber are trays for breaking the water up into a fine shower in order that the exhaust steam which enters through the separator attached to the heating chamber may heat the water to a point at or near boiling. The hot water set above the treating tank. In these are provided suitable supporting gratings carrying a wood-wool filter bed held in place by grids. The water from the treating tank may contain floating impurities that will not settle. These are caught by the filter and pure water passes up into the storage compartment above, where it is available for boiler purposes.

The filters are arranged in duplicate and so connected that one or both may be cut out of service for cleaning,

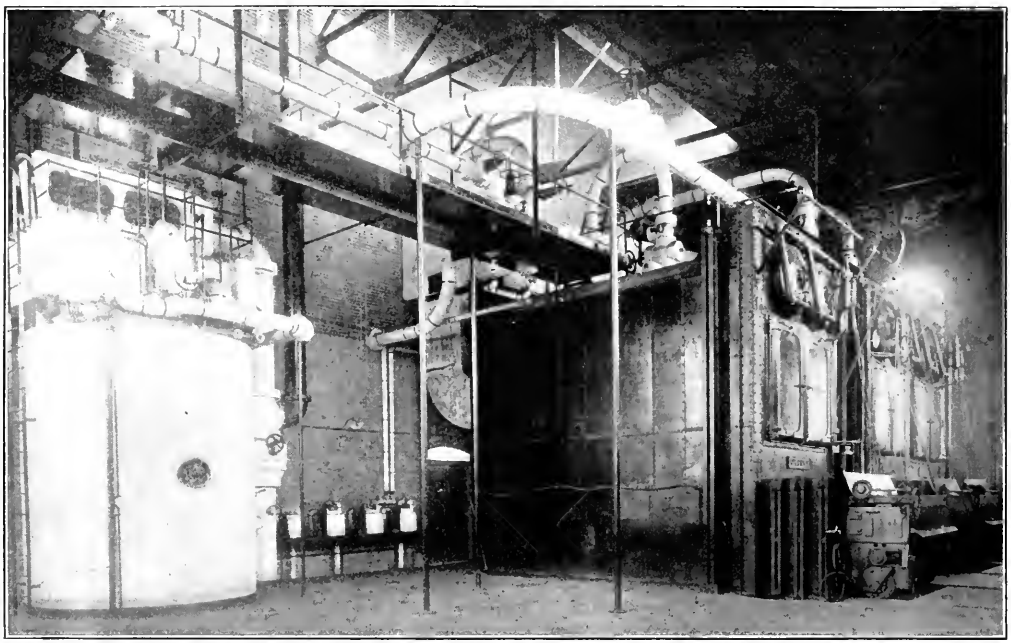

FIG. 2. THE BOILERS AND COMBINATION PURIFIER AND HEATER

then falls by gravity into the treating and sedimentation chamber, striking at the top a baffle which tends to distribute it uniformly and at the same time mix it with the reacting chemical which is fed into the raw water as at the same time leaving the heating section and the treating and sedimentation tank in service.

The amount of chemical to feed is determined by test, a simple equipment for the purpose having been provided.

PRINCIPAL EQUIPMENT UNITS OF GRANBY POWER PLANT

No.	Equipment	Kind	Size	Use	Operating Conditions	Maker
3	Boilers	Horizontal water-tube	550-hp.	Generate steam	150-lb. pressure, stokers, natural draft	Babcock & Wilcox Co.
3	Stokers	Chain grate	70-sq.ft.	Serve boilers		Babcock & Wilcox Co.
1	Stack	Tile and concrete	8x135-ft.	Serve boilers		Wiederholdt Construction Co.
1	Crane	Locomotive	10-ton	Unloading coal, etc.		Brown Hoisting Machinery Co.
1	Heater and purifier	Sorge-Cochrane	5420-gal. per hr.	Heat and purify feed water	Exhaust steam	Harrison Safety Boiler Works
2	Pumps	Duplex	10x6x10-in.	Pump boiler feed water	150-lb. steam	Epping-Carpenter Co.
1	Fire pump	Centrifugal	6-nozzle	Fire protection	Driven by 150-hp. Sprague motor	Alberger Pump & Condenser Co.
2	Engines	Simple Corliss	24x42-in.	Main units	150-lb. steam, 90 r.p.m.	Fulton Iron Works
2	Generators	Direct compound wound	400-kw.	Main units	440 volts, 90 r.p.m.	Sprague Electric Co.
1	Oiling system	Circulating and purifying		Serves main units and air compressor		S. F. Bowser & Co.
3	Oil pumps	Steam-driven	Two and six feed	Oil engines and compressor cylinders		Richardson-Phenix Co.
1	Air Compressor	Duplex	12, 19 and 12x14-in.	Compress air for tools, etc.	700 cu.ft. free air, 100 lb., 152 r.p.m.	Chicago Pneumatic Tool Co.
1	Crane	Traveling	10-ton	Serve engine room		Whiting Foundry Equipment Co.

it passes from the heating chamber to the treating and settling tank. This tank is made large enough to give the chemical time to act and the precipitate to settle to the bottom, where it can be drawn out through a sludge valve and discharged to any convenient point.

During this period the water passes down the outside and up the inside of the cone shown in the tank. At the top it is distributed between the two filter chambers

The proper proportion is then fed automatically into the system, which has a capacity to heat and treat 5420 gal. of water per hour.

When turning out the products for which the works was intended continuous service will be required from the power plant. The load night and day will run about the same, and reliability of service will be of the utmost importance, as discontinuance would entail a

large loss in the product under manufacture. For this reason duplicate generating units were installed, each capable of carrying the load while the other is held ready for service on short notice.

The engines are heavy slow-speed Corliss units, with cylinders 24x42 in., making 90 r.p.m., while the generators to which they are directly connected are really 600-kw. compound-wound direct-current machines, although rated at 400 kw., owing to the low speed. These massive units

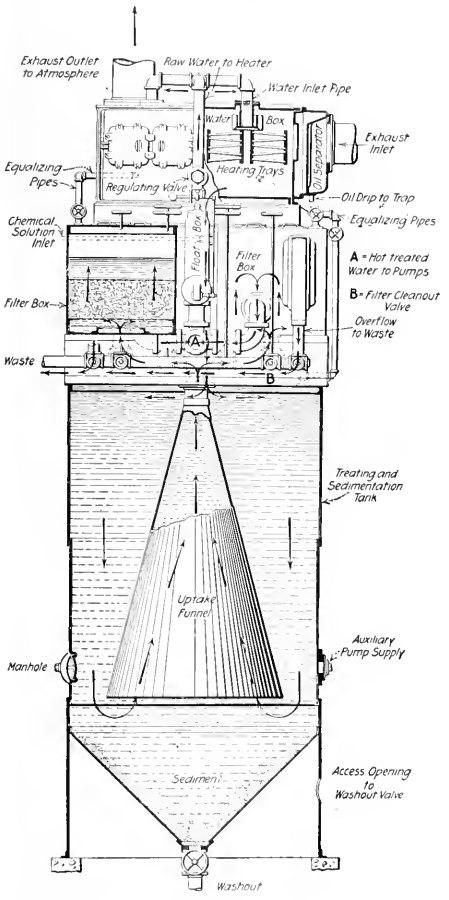

FIG. 3. SECTIONAL VIEW OF PURIFIER AND HEATER

are expected to care for the load with a minimum of upkeep and, above all, to give reliable service. The steam rate, although good for an engine of this type, is not of prime importance, as all of the exhaust steam will be utilized winter and summer.

Steam is supplied to each engine through an 8-in. pipe having a sectional area of 0.3171 sq.ft., or ⅛ sq.in. per kilowatt of rating. At 30 lb. per kw.-hr. the engine, at 50 per cent. overload, would require 18,000 lb. of steam, or 300 lb. per min. At 150 lb., and dividing by the area of the pipe, 0.3174 sq.in., gives for continuous flow a velocity of 2383 ft. per min. At quarter cutoff, however, steam would flow only one-fourth of the time, so that to supply the aforementioned amount of steam would require a velocity close to 9000 ft. per min. A receiver of course tends to equalize the flow. The longer the intervals between steam admissions, the larger this receiver should be. In the present case it was made 2¼ times the volume of the cylinder.

The exhaust piping is 10 in. in diameter, and for each kilowatt of rating it has an area of 0.197 sq.in. For 50 per cent. overload and continuous flow the velocity of the exhaust would be close to 12,000 ft. per min. At normal load this would reduce to 8000 ft.

Including building, chimney and all equipment, the total cost of the plant was $110,000, or $137.50 per kilowatt of rated output.

Granite Mountain Hoist*

The hoist now in course of installation at the Granite Mountain shaft of the North Butte Mining Co. is the largest electrically driven hoist of the Ilgner type on the two American continents. The hoist is designed to handle 7 tons of ore per trip. The ordinary hoisting speed will be 2700 ft. per min., but arrangements are made so that the speed can be increased to 3000 ft. per min. The equipment is designed to hoist from vertical depth down 4000 ft., and the cycles of operations have been chosen to give capacity from various levels approximately as follows:

300 tons per hour from the 2000-ft. level
250 tons per hour from the 3000-ft. level
200 tons per hour from the 4000-ft. level

The hoist has cylindrical drums 12 ft. in diameter and the rope to be used will be of 1⅝ in. plow steel.

The power required for hoisting will average about 1500 hp.; but to accelerate, the peak load will vary from 5500 to 4300 hp.

The direct-current hoist motor has a nominal continuous rating of 1850 hp., and has an intermittent rating of 2750 hp. It is guaranteed to handle 4500 hp. for a short time. The generator of the motor-generator set has a rating of 1500 kw. and can deliver 3750 kw. without trouble. The driving motor is 1400 hp.

The flywheel is 12 ft. in diameter, weighs 50 tons, and will have a speed of 400 to 500 r.p.m. The peripheral speed of the flywheel will be as high as 19,000 ft. per minute. In order to prevent any possibility of a flaw in this large wheel it is assembled out of sheets of rolled steel plate, each sheet being ½ in. in thickness. The total thickness of the combined plates is 21½ in. In designing this wheel the number of rivets was figured so that the plates are held together with sufficient pressure to hold any one plate by friction alone, eliminating any dependence on the shearing stress of the rivets. The entire wheel was carefully cut and finally polished and lacquered, so that it will present as smooth a surface to the air as possible and thus reduce friction. It was considered at one time that it might be advantageous to run the flywheel in a vacuum, but investigation proved that while such operation was feasible the application involved complications without sufficient increase in economy to compensate. The friction and windage losses of running the flywheel in the open air would amount to between 80 and 100 hp. This loss will be

*Abstract of a paper read before the Montana Society of Engineers, Butte, Mont., Apr. 10, 1915, by G. B. Rosenblatt, E. E.

reduced to about 50 hp. by enclosing the flywheel in a sheet-steel case carefully finished on the inside and fitting as closely as possible about the flywheel. Excluding the air from the cover and thereby running the wheel in a vacuum did not seem to reduce the loss by more than 12 or 15 hp., which would not justify the expense and complication of the necessary water-sealed glands, etc.

British Columbia Copper Co.

The report of the British Columbia Copper Co., Greenwood, B. C., for 1914 shows ore shipments from the company's mines tributary to the Greenwood smeltery amounting to 193,289 tons, of which 178,049 tons came from the Motherlode mine, 5332 tons from the Napoleon mine, 7920 tons from the Queen Victoria mine and 1988 tons from the Lone Star mine. No mention is made of the amount of metal produced or the average contents of the ore treated. The following statement of profit and loss is given:

Operating Disbursements	
Mining, smelting, freight, refining and selling charges, general office and administration expenses, maintenance and fixed charges and expenses incurred during the period the plant was closed down	$788,684.64
Custom ore purchased	162,434.84
Total	$951,119.48
Receipts	
Proceeds from metal shipments	$899,851.17
Miscellaneous earnings	11,503.76
Total	$911,354.93
Loss for year	39,764.55
	$951,119.48

A detailed analysis of the financial operations of this company is not possible from the condensed statements given by it, but it appears to us that, while a loss of only $39,765 is reported in the profit and loss statement just given, the company spent $540,330 more than it took in from operations. For example: At the end of 1913 it had a balance of quick assets of $122,406, and at the end of 1914 this balance had been spent, with an additional $417,925, this representing the excess of current liabilities over quick assets. This can be made clearer by the following figures as of Dec. 31, 1914:

Current Liabilities		
Accounts payable		$146,704
Amount advanced by Canada Copper Co.		340,000
Interest accrued to Canada Copper Co.		8,160
Loans and advances from banks		58,794
Reserve for sundry liabilities		500
Reserve for employer's liability		5,017
Total		$559,175
Current Assets		
Metals, smelter products, supplies, etc.	$112,801	
Prepaid insurance and taxes	4,693	
Sundry debtors	6,567	
Cash in banks	17,190	
Total		141,251
Current liabilities over current assets		$417,924
Balance of quick assets at Dec. 31, 1913		122,406
Total increase in current liabilities		$540,330
Loss reported in profit and loss statement		39,765
Other expenditures apparent		$500,565

This additional expenditure of $500,565 above those reported has probably been taken care of through the "Properties" account, but this account as given in the statement shows a decrease of $204,090.83 since the 1913 report was issued.

The report states that on account of the unsettled condition of the copper market during the last half of 1914 the company's smelter at Greenwood and operations at the mines from which the ore supply had been drawn were suspended in August. Development work was continued in a restricted way at the Copper Mountain property. It is stated that 6,200,000 tons of reasonably assured and probable ore of an average grade of 1.82% copper has been developed. There is also 750,000 tons of 1.54% ore developed. When this work has further progressed it is intended to arrange for improvements and equipment to treat these ores. The sum of $183,203 was spent in development work during the year. There are options outstanding on 11 claims for $188,000, upon which payments of $52,545 have been made. The amount shown in the financial statements of $3,400,000 for properties is the result of a preliminary valuation by the company's engineers of all its properties.

Extralateral Mining Rights

By A. L. H. Street*

In affirming judgment for defendant in a suit to recover damages for trespass upon a mining claim and wrongful removal of ore, the Supreme Court of Colorado lately decided in favor of the defendant in the case of Esselstyn vs. United States Gold Corporation (149 *Pacific Reporter*, 93). The defendant owned a senior lode mining claim on which a broad vein had its apex, but passed outside the side lines extended and under plaintiff's junior claim, where it was intersected by three veins, each of which had its apex on plaintiff's claim. It was decided that the defendant was entitled to the ore within the intersection by virtue of the provisions of Section 2336 of the United States Revised Statutes.

Anaconda-Amalgamated Distribution

The Amalgamated Copper Co. has issued notice that the statutory proceedings for the dissolution of the company have been completed, and the distribution of the assets can now be made on the basis stated in the company's circular of May 6. Each holder of one share of Amalgamated stock will receive one share of the new issue of the Anaconda stock, par value $50, and a cash distribution of $3. The transfer books of the Amalgamated Copper Co. will be finally closed on July 31 at noon, and the distribution will begin on Aug. 30 at noon on presentation of the certificates of stock at the company's office. Checks and Anaconda stock will be issued only to stockholders of record of July 31.

Costa Rica Production of Precious Metals decreased last year, according to a recent report from the Bureau of Foreign and Domestic Commerce, which says: "The following are the values of gold and silver mined and exported during each of the past five years: 1910, $811,186; 1911, $1,190,406; 1912, $817,565; 1913, $1,021,473; 1914, $888,599. The decrease during 1914 is partly explained by the fact that the Abangarez goldfield, the largest producer in former years, was shut down during nine months of 1914. In the early part of 1915 the Abangarez mines were placed under new management, and at present work is under way toward reopening these properties. The mines owned and operated by the Panama & Costa Rica Mining Co., the Aguacate Mines of Costa Rica, and the Montezuma Mines of Costa Rica were worked throughout the year with generally satisfactory results. These mines are mostly owned by American capital, and the entire product eventually reaches the United States."

*Attorney, St. Paul, Minn.

Editorials

Doctor Holmes

The death of Doctor Holmes on July 12 was not unexpected, inasmuch as he had been in poor health for a good many months and absent from his office in Washington. The latter is not to say that he had relinguished his duties. On the contrary, while he was at Fort Bayard, N. M., he kept a secretary with him and insisted upon directing many of the affairs of his bureau in spite of the solicitation of his friends who knew that he was overtaxing his strength and were apprehensive of what would be the outcome. This persistence on the part of Doctor Holmes was characteristic of him, however, and a fittting epitaph for him would be, "He lived with his work."

Doctor Holmes first attracted general attention by his services as chief of the Department of Mining and Metallurgy at the St. Louis Exposition. He filled that difficult position with an intelligence and suavity that charmed everybody; and he evinced a diplomacy that gave no ground for complaint to any jealous exhibitor. His particular interest, however, was in certain experimental technological work that was conducted at the Exposition, and upon the closing of the latter it was but natural that this work should be conducted by a technologic branch created in the Geological Survey and that Doctor Holmes should continue to direct it. When the Bureau of Mines was established upon the basis of the Technologic Branch it was equally natural that Doctor Holmes should become its first director.

The Bureau of Mines became his child. He practically created it, organized it and laid out its course. There is scarcely anything in it whereof the inception is not owed to him. He was ambitious for it and sometimes was criticized for the vaulting character of his ambition, although everybody recognized that there was never in his mind any thought of personal aggrandizement, but only thoughts for the prestige and public usefulness of his institution. For that institution he worked during every one of the 24 hours of the day except the few hours of sleep, traveling thousands of miles annually—enduring the hardships of railway tedium, poor food and miserable hotels—and holding intercourse with thousands of persons. The ability to get on well with people was one of his happy faculties, as also was his art of surrounding himself with able and loyal assistants.

He was never willing, however, to relieve himself of arduous duties by delegating them to his assistants. Their purpose, in his mind, was solely to enable his bureau to do more work, and he devoted himself indefatigably to finding it for them to do. With all of this he made the Bureau of Mines a great thing in remarkably few years, but in doing it he killed himself, leaving the mining and metallurgical industries of his country his eternal debtors. His special interest was the promotion of safety in mining. With keen perception he singled out the correction of the disgracefully high mortality in American mining as being the first big work that the Bureau ought to do.

Transition in Metallurgy

The present era is one of frequent and rapid changes in metallurgical practice. During the last three years—and this very likely will be repeated during the next three—processes have risen into prominence, enjoyed a superlative day and then begun to wane. If the prognostications of some of the most highly skilled of our metallurgists are to be credited, we shall soon begin to characterize the process of acid leaching of copper as the brightest and most transient of all the metallurgical stars. Because of practical necessity for a treatment system to fill in the bare places left by the better-known ones, leaching seemed to spring full-grown into being. Colossal plants have been built for its practice, but before even the completion of the greater plants a sturdy opponent has appeared to seriously question the economy of their working. Advocates of flotation maintain that there is no place for leaching in the copper field and that all that can be hoped for through leaching can be obtained with less cost, both of operation and of installation, through some flotation system. Whatever may be the truth of the matter, the fact remains that hardly any system of metallurgy—at least so far as wet treatments are concerned—is so firmly founded as to be able to disregard the advances of some other system. In Utah a highly economical system of roasting has made the return of chlorination possible. Even the cyanide process is challenged by flotation, and while not likely to be entirely supplanted, part of its field may easily be preëmpted. As to other processes, they are so many and so varied that it would be difficult to enumerate them, while the various combinations of two or more of them are almost without number.

*

Value of Money and Commodities

When the war began, prophecies about its effect upon trade and finance abounded. Some of these were good, but many of them—perhaps the major part of them—have failed of verification just as much as the military prophecies. Consequently it has become the tendency to express forecasts of the future now with a spirit of caution and humility. Yet in the forecasts of last fall there were many things foreseen fairly well. When England was demanding gold from us and sterling exchange was above $5, it was distinctly foretold that the gold would soon come back and that exchange would fall far below par. The enormous cost of the war, the tension in Europe's credit, and the gradual passage of some of the countries of Europe to a paper basis were prophesied and have come, or are coming, to pass. The purchasing of war material in this country is no surprise to us, although the magnitude of the transactions is indeed astonishing. Certainly the fulfillment of prophecies is such that the prophet of today should not be entirely without honor.

We may therefore listen with patience to the pronouncement that the warring nations of Europe, England perhaps excepted, are gradually going upon a paper basis and that a natural consequence thereof will be inflation; that the United States is being flooded with gold and through its new banking system will also possess the means for inflation. Assuming such to happen—and there is considerable evidence pointing toward it—the corollary is a decrease in the purchasing power of money and an increase in commodity prices. The index numbers show that some increase has already been experienced.

If this forecast indicates correctly the general trend of economics the lesson is that bonds will depreciate in value while stocks, especially the stocks of companies producing the staple commodities, will increase in value. In other words, it will be better for investors to own property than to lend upon it.

We have been startled by the extent of the rise in the prices of some of the metals—staple commodities of basic nature—especially spelter and copper; but while they will probably recede from their highest points, it may be that the world is entering upon a period during which the price for them, as well as the prices for all staple commodities, will prevail at a higher level than what we used to consider the normal previous to the war.

Lacing Method of Making Primers

Two methods of securing the cap and fuse in the primer stick of dynamite to obviate the liability of its pulling out were given in the *Journal* of June 19 and July 3. The first of these—lacing the fuse through the stick of dynamite—is so common that it may well be said to be the universal way of making primers. Almost everyone recognizes the danger of the fuse igniting the dynamite, with the resulting burned hole and all its disadvantages, and the likelihood of the powder train in the fuse being broken by the sharp bends where the fuse enters and leaves the stick of dynamite. When the latter is pushed into the hole with the tamping stick, the fuse on both sides of the dynamite is liable to be ground off by contact with the sides of the drill hole, breaking the powder train and causing misfires. However, the handicaps of this course, though commonly recognized, are often considered to be less than the disadvantages of some other method of inserting the cap. A practical miner sends the following brief in favor of lacing:

> About lacing the fuse in the powder, we shoot 30 and 40 holes in the winze and lace them all and never have more than 2 or 3 missed holes. They won't say it is the cap or fuse. I will bet none of them guys who say it makes the powder burn in the holes saw it do it. What do you think?

The writer of this letter makes the strongest argument possible against the method which he is advocating. If he has 2 or 3 burned holes out of a round of 30 or 40, he is losing 8 to 10% of his holes, and when the cost of shooting them over is considered, together with the additional time wasted in waiting for the powder smoke to dissipate, the blasting costs are going to be increased from 12 to 15%. In addition to this, it is obviously impossible to predict which holes are going to misfire, and if these misfires happen to be the cut holes, then the entire round is lost and will have to be shot again. The blasting expense is not only doubled, but the results from a round that is shot over are never so good as would have been obtained had the first shooting not misfired.

Lacing fuse through sticks of dynamite though common, easy and convenient, is bad practice. If other means suggested seem to have disadvantages out of proportion to the benefits they afford, some entirely new way should be sought rather than to stick to the old lacing method with its known faults and dangers. It was for this very purpose that the device described and installed in the later *Journal* article was devised. It is used advantageously in South Africa and could well be adopted in this country. It is simple, cheap and effective.

Charles Hayden, recently returned from an inspection trip through the West, stated that the policy of the copper companies in which he is an important factor would be to distribute in quarterly dividends such profits as the respective companies were earning if copper were figured at 13c. per lb. At the end of the year the surplus would be paid out as an extra dividend, always retaining in the treasury sufficient cash and cash assets to carry on the business of the company in a safe and independent way. This is certainly a very conservative policy. Adherence to it, or something like it, has enabled Utah to escape the necessity of ever having to reduce its dividend. Even during the disastrous second half of 1914 that company maintained its dividend while most of the others had either to cut or to suspend.

A well-known roller of sheet zinc wrote to the *Journal* with reference to an illustration used in an editorial in the issue of June 19 that a zinc stove-board blank would ordinarily be only about 36x42 in. of No. 9 sheet (0.018 in.) and not the larger size and heavier sheet that we stated. We plead guilty to an inadvertence. The instance that we had in mind was an occurrence, but in order to make the illustration more homely the case of a stove-board blank was substituted in rewriting the manuscript and the incongruity of what followed was overlooked. Nevertheless, the ratios remained the same of course; and so does the point that the high price for sheet zinc is seriously curtailing the consumption of it for many ordinary purposes.

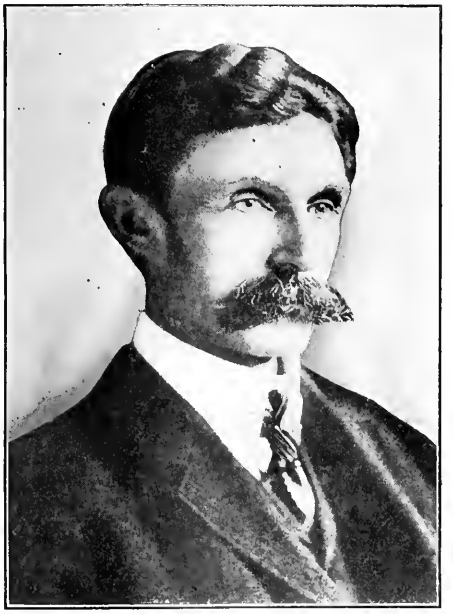
One European and neutral country has benefited by the war. The last report of the Bank of Norway shows the highest gold reserve ever reported by that institution, and the people are said to be unusually prosperous. In part this prosperity has been due to the high rates for ocean freights. Norway is a large vessel owner, and its ships are engaged in commerce all over the world. The boom in the freight business has been helped by an unusually good fishing season, adding to the prosperity of the kingdom.

It is understood that the new 2000-ton leaching plant of the Anaconda Copper Mining Co. is coming fully up to expectation. Since it was put into operation an average upward of 1900 tons of ore per day has been put through it and the tailings have averaged but 0.09% copper. The art of metallurgy appears to be making such progress that mammoth new plants are now put into operation without experiencing any of the infantile troubles that used to be expected.

Joseph Austin Holmes

Dr. Joseph Austin Holmes, chief of the Bureau of Mines for just five years past, or ever since it was organized under its present form, died at Denver, Colo., July 12, aged 55 years. His death was not unexpected by his intimate friends, but it will be the cause of widespread regret among the mining fraternity of all ranks, which he had served well for a number of years, since his work began long before the Bureau of Mines was constituted as a separate body.

Doctor Holmes was born in Laurens, S. C., in 1859. He was educated at local schools and at Chapel Hill, N. C., and graduated from Cornell University at Ithaca, N. Y., in 1880, taking the geological and scientific course. In the following year he was appointed professor



JOSEPH AUSTIN HOLMES

of geology and natural history at the University of North Carolina and remained there for 10 years. In fact, his connection with the university lasted very much longer, for he continued to lecture there for a number of years after he had given up the active duties of his professorship. In 1891 he was appointed state geologist of North Carolina and for three years devoted his time to the reorganization and improvement of the department. He had taken an active part in the geological exhibit at the Buffalo Exposition in 1901 and this pointed to his selection as head of the Department of Mines and Metallurgy at the St. Louis Exposition in 1904. While there, he originated the idea of a plant for testing fuels and structural materials, in the establishment of which he was ably aided by Messrs. Parker and Campbell. He continued in charge of the Geological Survey laboratories for three years, at first in St. Louis, then in Pittsburgh and finally in Washington. In 1907 he was made chief of the technologic branch of the Geological Survey and held that position until the Bureau of Mines was established by act of Congress on July 1, 1910. There were several candidates for the position of head of that bureau, but when Doctor Holmes was finally appointed, the universal approbation which greeted him in his new position was sufficient evidence of the wisdom of his selection.

Since his appointment, his activities had been incessant, all branches of the work receiving his constant attention and supervision, while at the same time he gave as much as possible of his time to outside societies and to committee work which would aid in the objects of the bureau. Thus he served on the International Mining Commission as representative of the United States to aid in the adoption of safety devices, both in this country and abroad. He was a member of the United States Conservation Commission and of the Mining Investigation Commission of the State of Illinois. The work of accident prevention and rescue, specially interested him, and it was largely owing to his influence that the plan of equipping a number of railroad cars as movable safety stations was adopted. He also used all his influence in favor of the measure for the admission into the United States free of duty of rescue and safety apparatus made abroad, in which he was finally successful. He had been suffering for some time from the disease of which he died, but it was not until the last few months that he allowed this to interfere with his varied activities.

Besides his official position, Doctor Holmes was a fellow of the Geological Society of America, member of the American Institute of Mining Engineers, of the Mining & Metallurgical Society of America, of the American Society of Mechanical Engineers, the American Society for Testing Materials, the Washington Academy of Sciences, the St. Louis Academy of Sciences and many minor scientific associations. He was a great traveler and was known personally to mining men in almost every part of the country. With many of these he first came in contact at the St. Louis Exposition in 1904, where the excellence and thoroughness of his work and his talents as an organizer were first generally recognized. From that time on, it may be said that he took the prominent position to which his ability and devotion to his work entitled him. Naturally, he was an able teacher, and his promotion was a serious loss to the University of North Carolina, which he had served faithfully for more than ten years and to which he continued to be much attached, although he was absorbed in his wider field of action.

Three years ago a friendly critic in *Coal Age* said of him—and his words have been amply justified since:

> Only his force of character, united to dexterity of action and ease of manner, could have secured from Congress the recognition, financial and otherwise, which has so far been accorded the Bureau of Mines. Many men have weight; Doctor Holmes has momentum. Lots of people know what to do; he knows how to do it. His diplomacy is the sort that enables a man, without deception or hypocrisy, to be seemingly the same to all men, yet varying with each, according to his peculiarity and according to the mind of the man at the time.

Doctor Holmes was married in 1887 to Miss Jeanie L. Sprunt, of Wilmington, N. C. He leaves two sons and two daughters.

PERSONALS

Sydney H. Ball is in Tennessee for 10 days on professional business.

H. W. Hardinge has returned to New York from an extended trip through the West

A. M. Plumb of the American Zinc Ore Separating Co., has been in the Silverton district, Colo., on business.

J. B. Tyrrell, of Toronto, Ont., will shortly go to examine some silver properties in the Port Arthur district of Ontario.

G. A. Loomis, representing New York parties, is making an inspection of some of the Big and Little Cottonwood properties in Utah.

R. C. Coffey, formerly superintendent of the Uwarra mill in North Carolina has returned to the Cobalt-Porcupine country in Ontario.

Hennen Jennings has gone to Ruby, Mont., whence he will proceed to San Francisco, where he will spend the remainder of the summer.

Fred H. Nye, of Denver, has been made mine superintendent for the Boulder Tungsten Production Co. with office at Boulder, Colorado.

F. W. Sherman has resigned from his position as superintendent of the Daly West mine, and will leave Park City, Utah, where he has lived for the past 15 years.

Franz Juretzka, of Breslau, a well-known German zinc metallurgist and contributor to the "Journal," is now serving as a volunteer in the Ersatz battalion of Grenadier regiment No. 11.

Walter Harvey Weed is at Butte, Mont., on mining examination work and expects to make a trip to Newfoundland on his return to examine some large copper deposits in that region.

John A. Baker, formerly construction engineer for the Tough Oakes mill in Ontario, has accepted the position of milling superintendent for Moose Mountain, Ltd., at Selwood, Ontario.

Prof. C. L. Crandall, dean emeritus of the College of Engineering of Cornell University was the guest of honor at a banquet given July 6 at the University Club by Cornell alumni of Salt Lake City.

H. M. Montgomery, chairman of the Chicago section of the American Society of Mechanical Engineers, has been elected vice-president and director of the Powdered Coal Engineering & Equipment Co., Chicago.

N. L. Heinz, who designed the Langeloth plant of the American Zinc & Chemical Co., completed the first unit of it and made provisions for the remainder, is now engaged with the American Steel & Wire Co. in the designing and building of the new zinc and acid plant at Donora, Pennsylvania.

The gold medal awarded by the British Institution of Mining and Metallurgy to Dr. Willett G. Miller, provincial geologist of Ontario, was formally presented to him on July 7 by Hon. W. J. Hanna, acting premier of the province. This is the first time that the medal has been given to a Canadian.

Dr. Bailey Willis has been appointed professor of geology at Leland Stanford University in California, taking the place of Dr. J. C. Branner, who is now president. Dr. Willis was for a number of years on the U. S. Geological Survey; more recently he has been consulting geologist and has conducted explorations in China and for the Government of Argentina.

Dr. Rukard Hurd, secretary of the Minnesota State Tax Commission, will resign July 15 to devote his time to iron-ore assessments and kindred subjects. Doctor Hurd is an authority on valuation of iron ores and has guided the Minnesota Tax Commission in the adoption of taxation methods on unmined tonnages on the Mesabi, Vermilion and Cuyuna ranges. He will be succeeded by Henry A. S. Ives, a St. Paul newspaper man.

OBITUARY

William C. Squier died at Rahway, N. J., July 7, aged 70 years. He was concerned with his father in the establishment of the New Jersey Zinc Works, and was connected with them for many years, retiring 15 years ago.

P. J. Tallon, assistant secretary of the Silver King Coalition Mining Co. died at Park City, Utah, July 4, aged 40 years. He was born in New York and had lived in Utah since 1884. He was elected mayor of Park City last year.

William H. Gorman died at Bedford Springs, Penn., July 7, after a stroke of paralysis. He lived at Oak Forest Park, near Catonsville, Md., and was President of the Gorman Coal & Coke Co., the Cumberland Coal Co., and the Piedmont Mining Co. He was also a director of several banks.

T. J. Vandergrift died at Columbus, Ohio, July 3, aged 52 years. He was born in Pittsburgh, and his first work was in transporting oil down the Allegheny River. Later he became an oil operator and was prominent for many years in Pennsylvania, West Virginia, Ohio, in the West and in Mexico. He was the first to introduce the use of natural gas in Pittsburgh. He was one of the first to study the relation of petroleum to geology and also one of the first to follow out the theory of anticlinals and synclinals. He was foremost in discovering oil territory in Pennsylvania, New York, Ohio and West Virginia and took first rank as a prospector, or "wildcatter." For many years he was one of the most progressive and successful oil producers and his judgment was considered excellent by many of the most prominent operators. In fact, wherever it was known that "T. J." had started a well or was about to start a well, leasing in the vicinity at once became active.

SOCIETIES

American Mining Congress—Directors of the Utah chapter at a meeting held July 7 decided on a campaign for increased membership. It is planned to give all persons interested an opportunity to join in the chapter's organized efforts to develop and aid the mining industry of the state. Accurate local mining information will be collected and compiled, and will be available to those interested. A. G. MacKenzie of Salt Lake has been selected as secretary by the executive committee.

Colorado School of Mines—On July 8, the board of trustees appointed as president William Battle Phillips, director of the Bureau of Economic Geology in the University of Texas. Prof. Phillips graduated from the University of North Carolina in 1877, subsequently spending two years at Freiberg and obtaining a mining degree. He is a member of the American Institute of Mining Engineers. He has been connected with numerous mining enterprises in the Southwest and is endorsed by officials of the U. S. Geological Survey and the U. S. Bureau of Mines. His duties will commence Aug. 1. Prof. William G. Haldane, who has been acting president of the school for the past two years will resume duties on the faculty as associate professor of metallurgy.

TRADE CATALOGS

The National Tube Co. has issued a bulletin, No. 20, which carries an index to all the bulletins preceding it.

Locomobile Co. of America, Bridgeport, Conn. Catalog. Locomobile Worm Drive Motor Trucks. 43 pp., illus., 8½x11 inches.

Sanford-Day Iron Works, Knoxville, Tenn. Sectional Catalog No. 25. Mine Wheels, Mine Trucks, Cars, etc. Illus., 8½x 11½ inches.

The Esterline Co., Indianapolis, Ind. Catalog No. 364. Golden Glow Incandescent Headlights for Mine, Railway and Industrial Service. 32 pp., illus., 6x9 inches.

The H. K. Porter Co. has just issued the eleventh edition of its catalog, which is really a textbook on locomotives. Because of the expense of preparation this book cannot be sent out indiscriminately, but will be mailed to those not in the market for locomotives on receipt of $1, a low price considering the excellence of the book.

Multi-Metal Separating Screen Co., 68 East 131st St., New York. Catalog: Pulmosan Respirator. 8 pp., illus., 9x6 inches.

This company has for years been manufacturing fine wire screens, as fine as 100,000 meshes per square inch, hence they could logically undertake the problem of devising a respirator to fill the needs brought to the company's attention by Dr. Otto Glogan, oto-laryngologist, delegated by New York State to make research along these lines. The Pulmosan Respirator devised consists of a combination of screening materials supplementing each other to form a perfect air filter which keeps out the finest dust particles.

Editorial Correspondence

SAN FRANCISCO—July 7

Natomas Consolidated Deeds conveying properties to Natomas Company of California were executed June 15. On June 17 delivery of Natomas securities in exchange for interim certificates representing first mortgage bonds of Natomas Consolidated was begun by the Mercantile Trust Co. at San Francisco. Natomas Co. will begin operations with the following capital obligations: Five-year 6% notes (estimated) $2,500,000; general and refunding mortgage 6% bonds $8,398,200; preferred stock (68,363 shares) $6,836,300; common stock (92,405 shares) $9,248,500. Total $26,983,000. Organization of the Natomas Co. authorized $3,000,000 of five-year notes but improvement in operating conditions diminished the amount by $500,000. None of the common stock will be in the hands of the public. This issue will be held by a British holding corporation which will issue its ordinary shares to former holders of second mortgage bonds and common stock in the Natomas Consolidated. The old second mortgage bondholders will receive approximately 25% or 50 shares for each $1000 bond. The old common stock holders will receive one share for $100 share formerly held in Natomas Consolidated. There will be some ordinary shares to cover a bonus arrangement. The trust company will be unable to distribute securities to holders of second interim certificates for several weeks owing to the fact that the British end of the transaction is not entirely completed. Also the capital liabilities of the holding company, for the same reason, cannot be given out for two or three weeks.

Revision of Tentative Mine Safety Rules was begun at a public hearing provided by the California Industrial Accident Commission. The hearing was attended by members of the California Metal Producers Association and operators and managers of a number of the large productive deep mines. Changes agreed upon at the meeting and suggestions or tentative changes from the text will be prepared by the committee who formulated the initial rules and the corrected form will be submitted to another public hearing. The most important change insisted upon at the meetings was a revision of Sec. 41, providing for the elimination of dust. The section was amended so that "inhalation of dust" will be substituted for "escape of dust." This permits the use of respirators instead of requiring the use of spray and water drills. The use of "T" rails in place of strap iron was also objected to; and some other changes asked. Until the rules are satisfactory to a majority of the attendants upon these public hearings they will not be adopted by the commission. There is no danger of the present mining engineer of the commission, or the commission itself, nor the committee of mine superintendents and mine workers who formulated the rules endeavoring to accomplish anything to the detriment of mine operation or to the workmen. The rules in some respects appear to be rather drastic and it is natural that some of the mine operators object to such rules as will require considerable expenditure of money to insure the safety of men, when they believe that less drastic measures may be adopted with equal success. But there is no reason for anyone to grow restive or belligerent respecting the outcome.

SMARTSVILLE, CALIF.—July 3

Renewed Activity In Smartsville, Yuba County, is attracting attention. Johnson, Hite, and Kibbe have leased from the Excelsior Water Co. what is known as the Lone Tree Hill quartz ground and are sinking on a 20-in. vein of gold bearing quartz. They have some good rock in sight. This ground was worked a little about 35 years ago. Some of the rock was very rich and some was hauled to Grass Valley and milled returning about $35 per ton. It is a free milling ore. A. McRae and A. Spencer have reached bed rock and are drifting for pay on their lease from the Excelsior Water Co. at Smartsville. There are some good streaks in these old channels. The gravel is hard and has to be blasted and then ground in some kind of mill to get the gold which is mostly small and flakey and rather hard to save as "quick" does not take hold readily.

BUTTE—July 7

Workmens' Compensation—When the state compensation law went into effect July 1, it placed 32,000 employees in Montana under the protection of the provisions of the law. These 32,000 workers will be paid for accidents that may befall them while in the line of their employment; about 25,000 of the men are insured under plan No. 1 in which the companies carry their own insurance. The liability companies have taken the risk for 5000 employees and 2000 are insured under plan No. 3 directly by the state, the money coming from employers. The 9 Anaconda Copper Mining companies, the 10 W. A. Clark companies and other big concerns carry their own insurance, having produced satisfactory proof of their solvency. The first employee to receive the benefits of the new law is Samuel Shepardson, of Butte who on July 1 had his leg sprained while in the employ of the Jones Transfer company. During first two weeks insurance company will pay his doctor and medicine bills, after that he will receive $10 per week as long as he is incapacitated. Had he been killed his family would have received $4000.

DENVER—July 8

Thirty Tons of Titanium Ore have been shipped from the northern New York mining field to the Colorado School of Mines, Golden, to be tested in the metallurgical plant by several flotation, electrostatic and magnetic separation processes.

Highgrading in the Cripple Creek District continues under rigid ban. In the district court last week, Judge Sheafor sentenced Thomas Moynahan, an assayer, to a term of from 2 to 4 years in the penitentiary. Another assayer is awaiting similar trial.

Standard Chemical Company has suspended operations in its reduction plant, in the Paradox valley southwest of Grand Junction, until the close of the European war. This policy throws about 180 men out of employment since the vanadium mines supplying this mill with ore were also shut down. But there is a healthy condition in the tungsten camps of Boulder county and it is estimated that the daily production of WO_3 has a value of about $8250.

Recent Transfer of the Independence Mine to the Portland Gold Mining Co. created a stir in the Cripple Creek district. Citizens believe that the deal will prove advantageous to the district as a whole in that operations will require more men than heretofore. The Independence mill was closed down preceding the transfer, the dump material having practically all been treated. There is a scramble for leases in the Independence ground and it is probable that the new owners will grant such privileges upon the same terms as prevail in Portland leases. The deed making transfer of ownership states the total consideration as $325,000.

The Mineral Production of Colorado for first half of 1915 shows little change. Gold production has been somewhat greater than for the corresponding half of 1914, this being due to the marked activities in the Cripple Creek district and to an increased dredging business at Breckenridge. Silver output remains nearly constant. Notwithstanding recent high prices for lead and zinc, figures show that the production of neither metal has risen materially up to this time. Tonnage of ore in Cripple Creek has been increasing every month since last fall. The estimated tonnage for June is 81,430 with an average gross value per ton of $16. It is predicted that, before the close of 1915, the district will be producing 100,000 tons per month.

To Comply with the Workmen's Compensation Law passed by the last session of the legislature, employers of Colorado, especially those engaged in mining and metallurgy, have negotiated with insurance companies for rates. On June 29, thirty managers of metal mines met at the Capitol building to discuss their findings in this matter and they arrived at the conclusion that they would either organize a mutual insurance company or secure their insurance directly from the state compensation fund, if the old-line companies that had attempted to force high rates did not recede from their octopus-like attitude. A committee, consisting of Fred Carroll, state commissioner of mines, D. W. Strickland, attorney, Ex-Gov. Jesse F. McDonald, Leadville, R. M. Henderson, manager of Wellington Mines Co., Breckenridge, and C. E. Anderson, Aspen, was selected to conduct final negotiations with the insurance concerns or to proceed with other schemes. Subsequently to conferring with this committee, the state industrial commission announced that it would approve a rate

$3.73 for all underground workers and a rate of $2.39 for all surface workmen, this amounting to a reduction of practically 10% from rates that had previously been insisted upon by the insurance concerns. Where medical treatment is not included in indemnities, the above rates will be further reduced 25%. Now the coal-mine operators are busy along similar lines. Insurance companies insist upon a premium of $7.49 per hundred dollars of payroll in coal mines. Appeal to the state industrial commission by the coal operators resulted in a statement from the commission that it would approve a minimum rate of $6 per $100 of payroll. The operators believe they can form a mutual insurance fund and make money at the $6 premium rate.

SALT LAKE CITY—July 9

The Utah Copper Co.'s Output for the first five months of 1915 amounts to 52,183,908 lb. copper. Production has increased from 8,009,646 lb. in January to 14,053,765 lb. in May, which is the largest month's production in the history of the company. This is an increase of about 75%. The June output was larger, exact figures are not yet available. There are at present 1500 men on the payroll at the mine, 1500 men at the mills, and 250 in the employ of the Bingham & Garfield railroad—all told 3240 employees, who are paid over $200,000 a month in wages. The production in April and May amounted to 26,168,913 lb. copper as compared to 26,415,995 lb. during the first quarter.

Enterprising Park City Men have erected on Lincoln highway parting of roads east of camp a big sign reading: "Only seven miles to Park City, Utah's greatest silver-lead mining camp, elevation 7000 feet. Population 4500. Total mineral production $150,000,000. Dividends paid to stockholders over $45,000,000. See the wonderful mines, big reduction mills and a modern city." The sign has already brought scores of transcontinental autoists to camp. Many are attracted by the wonders of mining on a big scale and they are stopping over and visiting the mines, and incidentally leaving a little money at the hotels and restaurants. But better still, they are carrying away good words for the old camp, which is considered incalculable in dollars and cents.

GOLDFIELD—July 6

The Goldfield First-Aid Society has been organized with 16 charter members, all miners employed in the local mines. These men have been under instruction of C. S. Arthurs of the U. S. Bureau of Mines, for several weeks, in first-aid and mine-rescue work, and it was upon his suggestion that the organization was formed. The men have made excellent progress and have now two efficient teams capable of performing first-aid and mine-rescue work for the Goldfield district.

SEATTLE—July 6

Large Cleanup on Tolovana has recently been brought into Fairbanks by Harry Patterson operating a lay in deep channel claims on the third tier of the right limit, opposite claim No. 5 Above Discovery, a claim on Livengood Creek. It amounted to about $2500 in coarse gold. There are many nuggets weighing from $5 to $10. It is estimated that he has taken out about three fourths of the gold from his dump, the remainder of which cannot be sluiced on account of the lack of water. The largest previous cleanup was $180.

The Output of the Fairbanks Placer Mines for the first six months of 1915 was $300,000 greater than for the corresponding period last year. This was due almost entirely to the earlier season and the abundance of water. The greatest benefit of the lengthened operating season is to the opencut mines, which were handicapped by the backward season and the cold, wet weather last summer. Harry Atwood, on 5 Below Discovery, Pedro Creek, and Wm. Goodrich, on 3 Below, started sluicing in the latter part of May, whereas it has rarely been possible in the past to start before the first of July. Unless dry weather interferes by cutting off the supply of sluice water during mid-summer, the opencut mines should have the best season in the history of the camp.

Broad Pass Country Is Showing Well under prospecting, according to many who have come out for new supplies. Highly encouraging results have been obtained by practically all operators now working in the district on lode claims on the mineralized zone which penetrates the district for an unknown length. The indications are that the camp will be one of the richest in the north. The gold occurs with arsenides. W. E. Dunkle, a mining engineer representing the Guggenheims, is developing a group of claims which the big syndicate has taken under option to purchase at a large figure. The Guggenheims have options on some 20 other claims in the Broad Pass country. There are about 50 prospectors in that district now.

WALLACE—July 7

Cœur d'Alene Mines Cut in on Power from Thompson Falls Plant—The Frisco mine and mill, the Morning mine and mill, the Greenhill-Cleveland mine and mill, and the Tamarack mine and mill began to use power from the Thompson Falls plant July 1. The first three properties belong to the Federal Mining & Smelting Co. The litigation which preceded the use of the Montana current has attracted widespread attention but it was not generally known that the power line had been constructed. This work has been going on for the past year. The use of the Montana power is the direct result of the excessive rates charged by the Washington Water Power Co., which has had a monopoly on the power throughout the Cœur d'Alene district. Repeated efforts on the part of the mining companies to obtain a lower schedule always met with failure. Litigation in the state courts and before the State Public Utilities Commission was won by the mining companies and the state legislature enacted a provision to meet the situation in this district whereby the mining companies could build power lines to the state line to receive outside power providing that they would not become selling agents for the power. The defense of the power company was that they could not sell their current at a lower rate and operate at a profit. Since the new power is being used however new contracts are being offered at greatly reduced rates by the Washington Water Power Co.

The Continued Idleness of the Hercules Mine since the departure from the district of the representatives of the A. S. & R. Co. is regarded as an indication that the efforts to settle upon a new smelting contract for the Hercules ore have been abandoned. The old contract for the Hercules ore was at $14 for freight and treatment and, the lead content to be settled for at the full New York price for lead. This netted the Hercules company about $12 per ton more than the other companies for the same grade of ore. The Bunker Hill company has a long time contract but the terms are to be revised every five years and the revision to be based on the average of all contracts in the district. If the Hercules was given the same contract as they had had before it would have meant a material reduction by the smelting company on the Bunker Hill ore. It is believed that if the negotiations have been abandoned, the Day interests who control the Hercules will construct a smeltery in the Cœur d'Alene or might reconstruct the old Northport smeltery. They have holdings of several thousand acres near Osburn which were acquired recently. It is hardly possible that the Hercules mine would remain closed during the construction of a smeltery. In case the mine were operated the ore would have to be stockpiled unless some temporary smelting facilities could be obtained. The Northport smeltery might possibly be utilized in this case or the old Panhandle smeltery at Ponderay, four miles from Sandpoint, might be rehabilitated and the plant operated until the plant at Osburn could be constructed. There is a good water supply, and lime and coke are all that would have to be shipped in. There would only be a 2-mile haul for the concentrates from the mill and a 10-mile haul for the crude ore from the mine, both hauls would be downgrade.

JOPLIN—July 10

Strike Situation—East of the Missouri-Kansas state line the ore production this week did not exceed 800 tons, the strike extending to all the mines of Oronogo, Duenweg, Webb City, Alba-Neck and Joplin. In Kansas and Oklahoma no effort was made to extend the strike. Mines were started Thursday, Friday and today on the old scale of wages, and there are more than enough of the striking miners ready to go to work. It is estimated that 75% to 80% of the strikers will return to their old jobs Monday morning, and some of them are sore enough to cause trouble if any strikers attempt to interfere with their going to work. Representatives of the Metal Mine Workers Union were haranguing the men today, with the assertion that they can get $100,000 to back them up in their strike. It is asserted that all but the floating element are ready to return to work. The operators have made arrangements for a sliding scale of wages, based on the average base price of ore the preceding month, this rate to hold for one month. No trouble is anticipated.

TORONTO—July 9

Bees and Smeltery Smoke—Ten farmers in the neighborhood of Thorold, Ont., have brought actions against the Coniagas Reduction Co., for amounts varying from $950 to $10,000, on the ground that gas from the company's smeltery at Thorold has killed all the bees within a radius of several miles. They also allege that the poisonous vapors kill vegetation, rendering farming or fruit-growing in the vicinity of the smeltery practically impossible.

The Mining News

ALASKA

KENNECOTT COPPER (Kennecott)—Copper production in June was approximately 9,000,000 pounds.

HUBBARD ELLIOTT COPPER (Strelna)—A. G. Elliott on way to property, where he will plan installation of new equipment at Strelna on Copper River.

ALASKA COPPER CORPORATION (Strelna)—H. W. Du Bois, consulting engineer, of Philadelphia, is at property to go over ground in preparing plans for production on larger scale.

ALASKA-JUNEAU (Juneau)—J. H. McKenzie announces that 9000-ft. adit tunnel now being used to deliver ore to company's pilot mill may be double-tracked when new mill is built.

MOTHER LODE COPPER (McCarthy)—Is to drive lower adit tunnel to ore. President Godfrey is at present in New York on business in connection with mine.

PORCUPINE (Porcupine)—Large cleanup, first this year, has been made on this property consisting of $17,000 in gold dust, result of 15 days' labor of 22 men. Some rich ground has been opened up and force is being increased with view of rushing development.

ALASKA GOLD (Juneau)—Manager B. L. Thane announces that work will be continued this year and during winter to prepare Kensington mine for producing ore for 500-ton mill to be started in spring. Mine is situated at Berners Bay, about 60 miles from Juneau. Work being started on transmission line to bring power from new Annex Creek power installation now in process of construction to Thane. Sam Vuch, discharged miner at Perseverance mine, was given one year in jail for assaulting shift boss with candlestick underground.

ARIZONA

Greenlee County

ARIZONA COPPER (Clifton)—According to final court decision company must pay to Greenlee County $40,000 of back taxes.

SHANNON (Clifton)—Copper production in June was 1,018,000 lbs. which was 6000 lbs. less than in May. Average price received for copper sold in June was 19.47c.

Mohave County

LOST BASIN (Kingman)—Recently organized to take over Scanlon mine will immediately build first unit of 100-stamp mill.

UNITED EASTERN (Oatman)—Plans to begin construction of mill within next few weeks. On 565 level free gold has made its appearance in vein material.

ARIZONA SOUTHWESTERN (Yucca)—Shaft at Copperville being unwatered and will be sunk to 500 level. Mill now being overhauled preparatory to resumption of operations.

Pinal County

MAGMA COPPER (Superior)—Ore reserve said to be 95,000 tons, averaging 7.6% copper and $4 to $5 in gold and silver. Company hopes to develop porphyry orebody at depth. Full capacity of plant will not be reached until completion of three-compartment shaft about October.

AMERICAN SMELTING & REFINING CO. (Hayden)—Has taken over Christmas mine near Hayden. Will construct aërial tramway 1½ miles long, a high power transmission line and make other improvements. S. H Sterman is superintendent.

Santa Cruz County

DUQUESNE M. & R. (Duquesne)—Work being rushed on alterations of mill at Washington Camp, installing new flotation machinery. Plant will have 100 tons capacity and will be ready for operation soon.

CALIFORNIA

Amador County

PLYMOUTH CONSOLIDATED (Plymouth)—Reported that new oreshoot in 2300 level is wider and contains more gold than in upper levels.

Eldorado County

MONTEZUMA (Nashville)—Good progress being made in deepening shaft. Property is being developed by owners of Plymouth Consolidated at Plymouth, Amador County. J. F. Parks is superintendent of both mines.

Kern County

ANTIMONY CLAIMS have recently been located in Greenhorn Mountains by Miles R. Martin of White River and Pat McCloskey of Bakersfield. Samples are reported to assay 85%. Property is being prospected.

BUCKBOARD (Randsburg)—Fraser Bros. have purchased lease. Former leasers worked only few weeks and extracted 31 tons of ore that milled $21.75 per ton. Mine contains some good orebodies.

KERN COUNTY LAND CO. (Bakersfield)—Antimony mine in San Emidio mountains being prospected with view to operating during summer time. Mine was located several years ago and is reported to contain valuable deposits of antimony.

Mendocino County

MANGANESE DEPOSITS recently discovered at Potter on Busch ranch will be developed by Eastern men interested through Dr. Lewis Lee.

Mono County

NEYLON (Laws)—Controlling interest taken over by Joseph S. Giroux, of Ely, Nev. New road is being built to mine situated about ten miles northeast of Laws.

MAMMOTH (Mammoth)—Prospective purchasers examining mine which was formerly producer. Ore low-grade but it is reported that it can be worked with profit if it will average $4 per ton.

Placer County

FEDERAL DRIFT MINING CO. (Dutch Flat)—Agreement between surface property owners and mining company has been practically completed for mining operations beneath town. Only three owners have withheld their signatures. It is expected to start this new tunnel immediately. Recent bedrock strike made by company half mile below town added to interest in undertaking. Dutch Flat was, in early days of California mining, one of richest hydraulic camps and it is evident that there is large amount of drift gravel beneath town. Company recently installed 4-stamp mill and an electric device for saving gold.

Siskiyou County

JUDDRIGHT (Fort Jones)—A. H. Lindsay of Sacramento has bonded this property on Indian Creek. Initial work will be driving of 600-ft. tunnel. Mine was rich producer in early days.

Trinity County

GOLDEN JUBILEE (Coffee Creek)—Since reopening mine which closed down several years ago, good grade of milling ore has been disclosed and it is expected to start mill soon. Mine was large producer when in former operation.

Tuolumne County

NYMAN MINES (Jamestown)—Charles E. Schafer, manager, has received authority from owning company at San Francisco to begin unwatering Santa Ysabel mine.

SPRINGFIELD TUNNEL (Sonora)—New tunnel is now in 2400 ft. The last 104 ft. was driven in 19 days. Raise at 2230 ft. mark cut gravel and will be initially used as an airshaft. At 2800-ft. point, another raise will be made.

COLORADO

Boulder County

BOULDER TUNGSTEN PRODUCTION CO. (Boulder)—Development work is in progress in 1905 shaft, under direction of Fred H. Nye, superintendent of mines. Pay ore has been opened on 125 level and crosscutting is in progress to develop Midnight vein. It is company's plan to continue work in shaft and eventually make connection with tunnel driven from Boulder Creek.

Clear Creek County

CLEAR CREEK COUNTY SHIPMENTS during June were 88 cars of crude ore and concentrate. Argo mill purchased ore to value of about $26,000; Chamberlain samplery at Idaho Springs bought ore worth $25,000; and Georgetown sampler paid out $12,000 in settlements, making total of $63,000.

San Juan County

HIGHLAND MARY, SHENANDOAH AND TRILBY, old producers of copper-silver ore, have been consolidated and will hereafter be operated under one management. Shenandoah is under lease to J. B. Houston. Ores from these mines are amenable to flotation and a plant of this sort is contemplated.

SILVER LEDGE (Silverton)—Mill is running steadily concentrating lead-zinc ore accumulated during last winter's operation of mine.

BAGLEY MILL (Animas Forks)—Arrangements are made for starting up this old plant to treat ores from Hermes and other mines. Dan McNaughton will be superintendent.

EMMA (Silverton)—John Mattivi has begun sending out his accumulated winter stock of high-grade lead-silver ore by jack-trains; trails in Ice Lake Basin having been recently opened for season.

MAYFLOWER (Silverton)—American Ore Flotation Co., lessees, has reopened this mine and is exploring it. Body of sulphide ore 9 ft. wide carrying silver and gold is under development. Oil flotation is in continual use at the Silver Lake mill, treating ores mined in Mayflower and other leased mines. D. L. Thomas is metallurgist and Philip M. Collins is mill superintendent.

San Miguel County

TOMBOY (Telluride)—Mill ran 29 days in June; crushed 11,500 tons ore yielding $48,700 bullion and $54,500 concentrates. Operating profit $42,500.

COLORADO MANGANESE MINING & SMELTING CO. owns 10 claims in Dry Creek basin from which it ships very rich ore running less than 1% iron. Ore is hauled 40 miles in wagons to Placerville. Plans are made to maintain shipment of 25 tons daily. This very pure oxide has a ready market with manufacturers of electric batteries.

Summit County

FOUR DREDGES of district are working steadily. Estimated recovery of gold during June was $80,000.

DUNKIN (Breckenridge)—Shipped 50 tons carbonate ore to Chamberlain sampler. Ore runs about 35 to 40% lead, 15 oz. silver and 1 oz. gold. Lessees are O. K. Gaymon, of Denver; J. A. Sumner, of Salt Lake City; and Thomas H. Knorr and W. W. Wharton, of Breckenridge. Lawsuit with Queen Mining Co. over extra-lateral rights has been adjusted out of court and operations will be pushed.

Teller County

STRATTON'S INDEPENDENCE (Cripple Creek)—Cable advices give May production 4743 tons ore averaging 8 dwts., 13 grains; low-grade mine and dump ore milled 9617 tons.

LAST DOLLAR (Altman)—Lessees Crumby and Gibbons, who control ground between 1000 and 1200 levels, have opened vein on 1200 level that is 2 ft. wide and averages $30 per ton.

ORPHA MAY (Victor)—Dump is being worked over by Garstin and associates who have installed screening and washing machinery and are shipping product worth about $20 per ton

MARY McKINNEY (Anaconda)—Mine practically closed down during installation of new electric machinery. Repairs to shaft also being made and it is probable that shipments of ore will be prevented for two months.

AJAX (Victor)—In Worthington lease in Block 13 ore-body has been opened for distance of 50 ft. which has width varying from 2 to 5 ft. and test shipments of higher grade product range from $100 to $200 per ton in gold.

GRANITE (Victor)—Leasers Loss and Kaser are developing block of ground on 1200 level. New ore shoot has been opened which has width of 2 to 4 ft. and assays $30 per ton. Raise in ore shoot indicates that vein is becoming wider toward surface.

UNITED GOLD MINES (Victor)—In the various properties controlled by this company, at least 20 sets of leasers are working and shipments are being made from Trail and Trachite, on Bull Hill, May B on Squaw Mt., and the W. P. H. and Damon on Ironclad Hill.

C. O. D. (Cripple Creek)—This mine produced heavily in former times, but was closed down because of drainage difficulties. It has been secured by parties who have incorporated C. O. D. Consolidated Mining & Development Co. Col. T. B. Burbridge, James E. Hanley, Virgil Mann and Frank Vetters are among incorporators. Five sets of leasers are already working underground, while one set is preparing to handle mine dump.

IDAHO

Custer County

LOST PACKER (Mackay)—Smelting plant on Loon Creek being prepared for blowing in. Apparatus for 50-ton flotation plant is arriving.

EMPIRE COPPER (Mackay)—During June 169 cars, about 8450 tons of ore, were shipped to Utah smelters. On July 5, new record made at mine by shipping 18 cars, about 900 tons. Ralph R. Osborn is superintendent.

Shoshone County

C. & R. MINING (Wallace)—Edward Roberts, manager, will immediately purchase new compressor and other equipment for mine.

HORST-POWELL (Little North Fork)—Crew of 30 men are stoping and developing this copper property. Transportation difficulties have been solved and crude ore shipments will begin at once. Plans for erection of 150-ton mill have been completed.

SNOWSHOE (Mullan)—North-and-south fissure recently encountered has been followed for distance of 160 ft. and drift shows from 8 in. to 2 ft. of high-grade copper ore entire distance. Strike was first made at point 1600 ft. from portal of No. 2 tunnel and has vertical depth of 650 ft.

MICHIGAN

Copper

KEWEENAW (Calumet)—Loading station is being cut in Keweenaw at ninth level. Openings show good copper.

WINONA (Winona)—Is milling 600 tons per day at this time and is adding to milling and mining force daily.

CHEROKEE (Houghton)—Resumption of operations at Cherokee is expected in short time, both drilling and trenching.

FRANKLIN (Houghton)—Large compressor is in commission and production will be increased this week to 1000 tons daily.

MOHAWK (Mohawk)—Mohawk's new shaft rock-house will be in operation within month, if progress in construction continues at present rate.

NEW ARCADIAN (Houghton) — New Arcadian's further development in amygdaloid lode in south drift at 9th level shows as good if not better grade of milling rock than shown anywhere in mine.

ONECO (Hancock)—An assessment is expected on Oneco, if New Arcadian developments continue as sensational as in past few weeks. This company has 70,000 shares upon which $8 per share has been paid in.

AHMEEK (Ahmeek)—Sensational stories of rich strikes in exploratory drilling are untrue. One diamond drill is working. This drill is taking the first step in a cross-section. Yesterday it struck ledge, so utter absurdity of turning out a core from famous Calumet conglomerate is realized.

WYANDOT (Houghton) has unwatered shaft and is continuing drifts on 9th level with fairly good showing. They are making drill tests at present and orders are being placed for new machines. Resumption of sinking in winze will follow shortly. Assessment called last week was generally anticipated by shareholders.

NEW BALTIC (Houghton)—Shareholders of New Baltic are apparently pleased with plans for development of property through New Arcadian, and assessment plan is generally meeting with approval. In meantime development work at Arcadian continues to show most excellent stamp rock with each new blast.

Iron

TRADERS (Iron Mountain)—Mine will not be operated this season. It is an openpit and has shipped for several seasons.

INDIANA (Iron Mountain)—Several small lenses of high-grade ore have recently been found here. Considerable development work is being carried on. Regular shipments are now being made to docks at Escanaba. The inflow of water is greater than it was. About 800 gal. are now being taken care of. Eighty men are employed underground and on surface.

MAAS (Negaunee)—Cleveland-Cliffs Iron Co. has started shipping big stockpile here. Mine has been idle since last fall. There are about 300,000 tons of ore in stock. The bessemer is now being moved. This company has about 3,000,000 tons in stock on Marquette range. The sales for this year are close to 2,000,000 tons. Part of ore in stock runs high in silica and cannot be easily disposed of at this time. Production of the company's mines at present time is at rate of 1,500,000 tons per annum.

CHARCOAL IRON CO. OF AMERICA (Marquette)—This is title of company formed to take over Lake Superior Iron & Chemical Co. This latter company was placed in the hands of a receiver two years ago, when iron market became dull. Holdings were sold in Federal court in Marquette for $4,-000,000. Bondholders bought in property and will issue preferred and common stock to holders of bonds of Lake Superior Iron & Chemical Co. Management will remain the same and general offices will be maintained at Marquette. At present time only two of the company's six furnaces, Boyne City and Newberry plants, are in blast. Other plants are located at Chocolay, Ashland, Manistique and Elk Rapids. Ashland and Manistique furnaces will be blown in as soon as repairs now under way are completed. Concern has large timber holdings in upper Michigan and Wisconsin and owns lease of Yale mine on Gogebic range, which is owned by J. M. Longyear.

MINNESOTA

Duluth

MINNESOTA STEEL—Official announcement made that completion of Minnesota Steel Co.'s plant will be rushed. Already 500 men have been employed. Actual production of steel will begin by November. In addition, erection of 100 more employees' residences is planned.

Cuyuna Range

CUYUNA RANGE—On North Range, Rowe mine still leads in activity, having two hydraulic units at work stripping. Their concentrator will be ready by August 1. Hill Crest and Mahnomen stripping operations are progressing, as is also the stripping of part of Armour No. 1 orebody. Pennington pit is unwatered, although no work is being done. Inland Steel Co. is operating its Thompson pit and Armour No. 2 mine. Concentrator at Thompson is satisfactorily producing 600 tons daily. Circular concrete shaft at Croft mine is down 145 ft., being 40 ft. into ledge. Kennedy, at Cuyuna, is shipping 750 tons from skips, and will ship its 100,000-ton stockpile. On South Range, Wilcox is shipping steadily, and increasing its production. Brainerd-Cuyuna, at Brainerd, hoisted its first ore on Sunday, July 4, on which date the stockholders held a picnic on property.

MONTANA

Fergus County

SPOTTED HORSE (Maiden)—Plans being made for construction of cyanide plant. Property said to have been one of biggest gold producers in state since its discovery in 1881.

Hill County

HAVRE OIL AND NATURAL GAS (Havre)—Reports from Havre indicate that gas was struck June 3 in third well drilled by company, which flows between 7,000,000 and 10,000,000 ft. of gas every 24 hours. All efforts to cap flow failed because of great pressure of gas. Noise of escaping gas is heard mile away and precautions have been taken to prevent fire. Two lengths of casing were extended above ground so as to carry the gas further from danger. Town of Havre wild with excitement over strike.

Lewis and Clark County

SCRATCH GRAVEL DISTRICT NEAR HELENA—Operations in this district, which have been carried on by Helena Mining Bureau, have been discontinued for reason that claims leased by the Bureau have not come up to desired expectations. Machinery which had been installed on these claims is now being moved to near Clancy, where Bureau will start development work on Silver King claim. Of four claims developed by Bureau, Hawkeye mines, within city limits of Helena, is only one which has shown enough promise to warrant continued operations.

RICH STRIKE IN DRY GULCH NEAR HELENA—One of the richest strikes made in recent years in the gold district tributary to Helena is reported from a property a mile and a half south of Helena in Dry Gulch. Property is owned by Peter Rowan. There is a 450-ft. tunnel on the claim, in which a vein was discovered which is believed to be the much-sought-for "mother lode." Vein averages in width from 3 to 5 ft. and average values in previous operations ran from $7 to $8 a ton. Claim adjoins the Jumbo, a famous gold producer a number of years ago.

A. B. MELZNER VS. BRITISH-BUTTE MINING CO (Butte)—June 25 Judge McClernan finished hearing testimony in case of A. B. Melzner against W. E. Ward on injunction to prevent

Ward from interfering with big De Hora dredge at Rocker, which Melzner bought in at sheriff's sale last February, ordered to satisfy a judgment against the defunct British-Butte Mining Co. Judge McClernan granted temporary restraining order to prevent further interference with dredge by Ward, who had started to dismantle with apparent intention of selling it for scrap. Order will hold good until the final trial and determination of case involving ownership.

Silver Bow County

BUTTE & SUPERIOR (Butte)—Will proceed at once with development of Butte-New York properties of which Butte & Superior owns controlling interest. Butte-New York controls Butte-Milwaukee group which lies east and north from Butte & Superior's Black Rock mine. Butte-New York claims are zinc properties. Development will be carried on from 1200 and other levels of Black Rock.

MINING ACTIVITY IN WALKERVILLE DISTRICT—Great deal of work being done in and around Walkerville where some of first mining was done in Butte. Many leasers are busy developing and shipping ore and steps are being taken to unwater the old Lexington mine. Work has been started to repair the shaft and install pumps on the 300 and 500 levels. Contractors have been at work deepening Moose shaft, an auxiliary of Badger State. Work is being done to connect these shafts at a depth of 1300 ft. George Stephens, mayor of Walkerville, is making weekly shipments of gold and silver ore from Moulton. Development work is continued on Home Run mine and Frank Whitman is shipping ore regularly from his lease on Fraction which carries high silver and gold. Sam Hoar has several men working on his lease on Belle of Butte and is making preparations for regular shipments.

NEVADA

Elko County

BLUSTER CONSOLIDATED (Jarbidge)—New mill, started last month, now treating 40 to 45 tons daily; treatment by amalgamation.

ELKO MINING (Jarbidge)—Alpha mill closed down indefinitely. Small amount of development work will be continued in hope of opening more ore.

Nye County

TONOPAH ORE PRODUCTION for week ended July 3 was 10,100 tons valued at $207,760, compared with 10,642 tons week previous. Producers were: Tonopah Belmont, 3547 tons; Tonopah Mining, 2450; Tonopah Extension, 1820; West End, 1002; Jim Butler, 1100; North Star, 107; and miscellaneous leasers 74 tons.

MONITOR-BELMONT (Belmont)—New mill being constructed will have ten 1600 lb. stamps and one 6x10 tubemill. Flotation equipment will also be included. It required 18 horses 8 days to haul tubemill from Tonopah, distance of 50 miles.

Storey County

COMSTOCK PUMPING ASSOCIATION (Virginia)—Repairs finished to east crosscut drain on the 2700 level.

YELLOW JACKET (Gold Hill)—Mill received 1005 tons of dump rock. One bar of bullion shipped to smeltery.

UNION CONSOLIDATED (Virginia)—West crosscut on 2650 level in porphyry and quartz. Reopening north drift on 2500 level.

CONSOLIDATED VIRGINIA (Virginia)—Jointly with Ophir on 2500 level old main north drift reopened to Mexican line. Resumed work in east crosscut to 2700 level winze.

MEXICAN (Virginia)—Important prospecting started in west crosscut on 2700 level. On 2500 level ground in main Comstock reopened. Mill crushed 155 tons, averaging $14.25 per ton.

OPHIR (Virginia)—Saved 323 cars of mill ore from Central tunnel and shipped 250 tons to mill. Central tunnel continues to show large tonnage and 8-ft. body of quartz to be explored to the north. Machine drills are to be installed to continue Andes crosscut.

NEW JERSEY

Sussex County

NEW JERSEY ZINC (Franklin Furnace)—A 250% stock dividend has been declared payable on or after July 21 to stockholders of record at noon July 10. This increases the capital stock to $35,000,000.

NORTH DAKOTA

Mercer County

DRILLERS ENCOUNTERED GAS at depth of 75 ft. 1½ miles west of Expansion.

UTAH

Juab County

TINTIC ORE PRODUCTION during the first half of 1915 amounted to total of 2770 carloads estimated at 138,500 tons, valued at $3,480,000. Total for June was 568 carloads, estimated at 28,400 tons, and valued at $710,000. These figures compare with total yearly shipments from camp in 1914 of 6094 carloads, and fall little below average. Chief and Mammoth in June, exceeded any of their other monthly production so far this year. There were 22 shippers in June and 34 in first half of 1915. The individual productions for first half of 1915 are in carloads: Sioux mill dump, 241; Iron Blossom, 502; Chief Consolidated, 335; Mammoth, 110; Centennial-Eureka, 530; Eagle & Blue Bell, 245; Gemini, 103; Grand Central, 83; Dragon Consolidated, 91; Victoria, 36; Gold Chain, 42; Beck Tunnel, 34; Bullion Beck, 35; May Day, 61; Carisa lease, 16; Sioux Consolidated, 18; Uncle Sam, 12; Opohongo, 9; Colorado, 30; Eureka Hill, 25; Godiva, 9; Yankee Consolidated, 19; Black Jack, 4; Tintic Standard, 9; Lower Mammoth, 62; Ridge & Valley, 1; Utah Ore Sampler, 3; Minnie Moore, 4; Utah Mining-Continental, 3; United Tintic, 1; Clift lease, 1; Dubuc lease, 1; Salvador, 1; Copper Queen, 1.

OHIO COPPER (Bingham)—New leasing company is working at capacity, treating 2400 to 2500 tons of ore daily.

GRAND CENTRAL (Mammoth)—Shipments are being made from nearly all levels between 600 and 2200. Copper ore of good grade is coming from lower workings. June output amounted to 18 cars.

Piute County

MINERAL PRODUCTS (Marysvale)—Construction on the new mill to treat alunite for potash has been started. Work is under contract to Westinghouse, Church, Kerr & Co. Roads in cañon are being put in shape for autotrucks, and tramway mile long is to be built to loading station in Cottonwood Cañon. About 20 men are employed at mine on development. L. K. Kennedy will be mine superintendent.

Summit County

PARK CITY ORE PRODUCTION for month of June shows total of 8759 tons from five principal shippers and approximately 500 tons from others, making total for camp of 9259 tons, estimated at $370,360. Total for first half of 1915 is approximately 50,000 tons. Estimated valuation is $2,000,000 for six months. These figures may be compared with a total for the camp in 1914 of 75,000 tons, and is considerably above half-year average production. Principal producers were: Silver King Coalition, 22,498 tons; Daly-Judge, 11,636; Silver King Consolidated, 4594; Daly West, 7391; Ontario, 521; Daly, 520; D. W. Quincy, 100; American Flag, 25 tons.

WASHINGTON

Okanogan County

ARLINGTON MINING CORPORATION (Okanogan)—H. I. Stolfire states that company plans to install considerable new equipment in Arlington mine.

Stevens County

COPPER KING (Chewelah)—Judge W. H. Jackson, in the Superior Court of Colville, ordered accepted bid of $125,000 for property by J. W. Douglas of Orient. This will net shareholders about 5c. per share. Property was in receiver's hands.

WISCONSIN

Zinc-Lead District

MINERAL POINT ZINC (Mineral Point)—Construction of new sulphuric-acid plant at Mineral Point is under way. New methods will be used to protect surrounding vegetation from gas fumes.

ENTERPRISE (Platteville)—H. E. Stephens and Chas. Kistler are preparing to operate Enterprise roaster for custom work.

NATIONAL SEPARATING CO. (Platteville)—New equipment is being installed which will increase capacity of roasting plant 50 per cent.

VINEGAR HILL ZINC (Platteville)—New milling plant on Kittoe Mine at Lenton has been placed in operation.

FIELD (Scales Mound)—New 400-ton mill has just been completed on Thompson lease at New Diggings.

UTT-THORNE (Platteville)—This company has purchased roasting plant of Wisconsin Separator Co. at Benton and will engage in custom roasting.

CANADA

Alberta

SOUTHERN ALBERTA OIL CO. (Calgary Oil Field)—President Wm. Livingston announces that this company has flowing well. Rising oil burst safety valve at top of hole and is flowing over surrounding area. Depth of well is 3527 ft. and pressure when valve blew off was 350 lb. per sq.in.

British Columbia

BRITISH COLUMBIA COPPER (Greenwood)—After idleness of ten months Greenwood smeltery has resumed operations by blowing in one blast furnace. About 50 men will be employed at plant and 50 more at Mother Lode mine. Operations will be brought up to full normal capacity as rapidly as possible.

Nova Scotia

DOMINION STEEL CORPORATION—No. 7 blast furnace was blown in July 5, making four furnaces now in operation. Production for June: Pig iron, 22,552 tons; steel ingots, 28,680; rails, 13,044; rods, 6435; bars, 797; wire and wire products, 3167 tons.

Ontario

LUMSDEN (Cobalt)—Operations have been resumed on a small scale. Crosscutting will be undertaken on 50-ft. level in hope of cutting Timiskaming vein.

DOME (South Porcupine)—General manager has given out statement to effect that rich ore struck by diamond drilling when opened up by drifts is in richness and extent beyond expectations. He says "The mine-run showed better than 27,000 tons milled yield bullion production of about $121,000," and concludes by saying "we have openings now in the mine in such high-grade ore that we can make almost any production which you might feel justified in wishing to maintain."

SOUTH AMERICA

Chile

BRADEN (Rancagua)—Production for June was 2,542,000 lb.. Treated 91,000 tons ore averaging 2.1% copper. Average extraction was 77.21%.

AFRICA

Rhodesia

TOTAL PRODUCTION OF METALS in Rhodesia for the five months ended May 31, is reported as follows: Gold, 362,471 oz.; silver, 71,397 oz.; copper, 1313 tons; lead 12 tons. The output of other minerals was: Chrome ore, 17,543 tons; asbestos, 231 tons; coal, 151,558 tons. There were also 33 carats of diamonds reported.

The Market Report

Metal Markets

NEW YORK—July 14

All of the principal markets except spelter were dull during the last week, and were inclined to be reactionary, although the recession in quotations was but trifling.

Copper, Tin, Lead and Zinc

Copper—Exactly the same conditions continue to exist as were reported last week, but there was less business done. Such as was done by the principal producers was for special shapes, special brands, special terms or otherwise that were in no way indicative of the market. On regular business they maintained their asking prices of 20@20¼c., regular terms, but it was admitted that the actual market was below that, and, in fact, copper was offered during the week by outsiders as low as 19½c., regular terms. On the whole, however, the market during the last week cannot be characterized as otherwise than merely nominal.

Copper Sheets are understood to have brought 25@26c. per lb. The principal manufacturer makes no base quotations. Wire is quoted at 21½@22c. per lb. at mill.

Copper Imports reported by the Department of Commerce for the month of May included 10,389,201 lb. in ore; 655,041 lb. in matte; 9,495,690 lb. pigs, bars, etc.; 745,867 lb. old, scrap, etc.; total, 21,285,799 lb. Exports for the month included 39,637,810 bars and ingots; 8,623,823 lb. rods and wire; 2,130,402 lb. plates and sheets; 750,906 lb. scrap, etc.; total, 51,202,941 lb. In addition there were exported 2910 tons ore and matte, containing by values approximately 153,220 lb. copper. This brings the total imports for the five months ended May 30 up to 43,929 long tons; exports, 134,405 tons.

Copper Imports for the week ended July 3 are reported by the Department of Commerce as follows: Metal, 5,236,918 lb.; contents of ore and matte, 759,585 lb.; total, 5,996,503 lb. These imports were nearly all from Chile, Peru and Japan. Exports of copper for the week were 7,171,707 lb.; the chief items being 3,859,650 lb. to Great Britain; 2,477,231 lb. to France; 672,000 lb. to Denmark.

The Consolidated Arizona Smelting Co. is reported to be doubling its smelting capacity at Humboldt, Ariz. This company is said to be making money now for the first time in its history.

Tin—Deliveries were rather large and there was some pressure to sell, which caused the price to recede a little, buyers being already well provided.

Exports of tin from the Federated Malay States five months ended May 31 were 20,599 long tons in 1914, and 19,270 in 1915; decrease, 1329 tons.

Lead—The principal producers maintained a price of 5.75c., New York, which was realized on some transactions, but there was a reappearance of lead from second-hands which was offered in considerable quantity at rather large concessions from the producers' price.

Spelter—Relatively little business was reported done by first-hands, but there was rather a large tonnage reported sold in trading business, considerable spelter being offered for resale. The conditions of these transactions were rather curious. A moderate tonnage of spelter was reported sold for export

The London quotation for spelter continues unchanged at £100, but this quotation is purely nominal.

The number of new distillation furnaces being added at the Sand Springs smelting works is two. One furnace is being added at Chanute, and one at Bruce. The old plant at Nevada, Mo., is to be put in operation about the end of August with four Belgian blocks. E. V. Lanyon is building two Belgian blocks in connection with the east plant at Pittsburg, Kan., but on his own account.

The U. S. Steel Corporation is reported to be making good progress at Donora, Penn., with the construction of its new zinc and acid plant.

Exports from Baltimore for the week included 474,874 lb. zinc dross to Liverpool.

Spanish Exports of Metals and Minerals for the four months ended Apr. 30 are reported by the "Revista Minera" as follows in metric tons:

	Metals		Ores etc.	
	1914	1915	1914	1915
Iron	4,027	52,689	2,673,020	1,348,945
Copper	6,391	5,562	48,470	12,811
Copper precipitate	3,720	3,604	....	....
Lead	55,308	45,407	879	274
Zinc	502	1,400	29,958	5,194
Quicksilver	827	699	....	....
Manganese	....	....	5,913	2,326
Pyrites	....	....	1,070,727	461,764
Salt			201,600	144,268

Imports of coal for the four months were 455,159 tons, a decrease of 484,569 tons; of coke, 63,802 tons, a decrease of 62,699 tons.

DAILY PRICES OF METALS IN NEW YORK

July	Sterling Exchange	Silver, Cts. per Oz.	Copper Electrolytic, Cts. per Lb.	Tin Spot, Cts. per Lb.	Lead New York, Cts. per Lb.	Lead St. Louis, Cts. per Lb.	Zinc St. Louis, Cts. per Lb.
8	4 7650	47½	*19 15 @19 55	38¾	5.75	5 57½ @5.67½	19.75 @22.25
9	4 7681	47½	*19 30 @19 40	38¾	5.70 @5.75	5 55 @5.65	20.00 @22.50

*Nominal.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York, 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

July	Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos.	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts. per Lb.
8	22 15/16	77¼	79	93½	19 32	170	165½	23¾	5.17	100	21.73
9	22½	77⅝	78⅞	94	19 42	172	166¼	24½	5 22	100	21.73
10	22½	....	....	....	....	....	....	....	.....	....	....
12	22½	77⅝	79	93½	19 32	171¾	165½	25½	5 43	100	21.73
13	22½	78¼	79½	93½	19 32	172½	166¼	25 3/16	5 36	100	21 73
14	22 9/16	78	79¼	93½	19 32	171½	165½	25¼	5 35	100	21.73

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Other Metals

NEW YORK—July 14

Aluminum—The market has been fairly active, with some increase in sales. Prices are unchanged and firm, the current quotation being 32@33c. per lb. for No. 1 ingots, New York.

The latest London quotation for No. 1 ingots is £130@140 per long ton; the average being equal to 29.33c. per lb. The price is advancing.

Antimony—Fair sales are reported but the market is nervous and unsettled though there has been no material change in prices. Chinese and other ordinary brands bring 37½@40c. per lb. The special brands are nominal, 50@52½c. per lb. being asked for Cooksons.

Nickel is steady and unchanged at 40@45c. per lb. for ordinary forms, according to size of order. Electrolytic 3c. per lb. higher.

Quicksilver is strong and in good demand, with prices higher. New York quotations are $94 per flask of 75 lb. for large orders; $95@100 for smaller quantities, with sales chiefly at the higher figure. San Francisco price is reported by telegraph at $90@95 per flask, with business fair. London has had a sharp advance and the price is now £18 5s. per flask, with £18 2s. 6d. quoted from second hands.

Minor Metals—Current sales of bismuth are at $2.75@3 per lb. New York. The London price is quoted at 10s., or $2.40 per lb. there—**Cadmium** is quoted at 6s., or $1.44 per lb. in London; $1.50 per lb., New York.—**Tellurium** is reported sold at 80s., or $19.20 per lb. in London.—**Selenium** is quoted at $2@3 per lb. New York for larger quantities; $4.50@5 for retail lots.

Gold, Silver and Platinum

Gold in the United States July 1 is estimated by the Treasury Department as follows: Held in Treasury against gold certificates outstanding, $1,173,799,069; in Treasury current balances, $206,526,508; in banks and circulation, $600,777,874; held by Federal Reserve banks against notes, $12,445,564; total, $1,993,549,015. This is an increase of $78,765,019 over the June report.

Gold production of the Transvaal is reported by cable at 755,280 oz., or $15,611,638, in June. For the half-year ended with June it was $84,475,128 in 1914, and $91,114,352 in 1915; an increase of $6,639,224 this year.

Platinum remains quiet with moderate sales and quite steady. Dealers ask $37@39 per oz. for refined platinum and $41@44 per oz. for hard metal.

Our Russian correspondent writes that the market remains generally unchanged, but a slow decrease in prices is to be noted. The demand in Petrograd is good, but the difficulties in exporting the metal detain the business. At Ekaterinburg the speculators buy voluntarily small portions of platinum from the starateli. The quotations are: at Ekaterinburg, 8.20@8.30 rubles per zolotnik; in Petrograd, 33,000@33,200 rubles per pood, for crude metal, 83% platinum. These prices are equivalent to $31.02 and $32.44 per oz. average, respectively.

Silver continues quiet, with small fluctuations in price. Some silver is going to the East from San Francisco; shipments from New York are only moderate, but seem sufficient at present to satisfy the demand.

Exports of silver from London to the East Jan. 1 to June 30, as reported by Messrs. Pixley & Abell:

	1914	1915	Changes
India	£3,863,000	£2,647,000	D. £1,246,000
China	40,000	5,000	D. 35,000
Total	£3,933,000	£2,652,000	D. £1,281,000

Coined silver in the United States July 1 is estimated by the Treasury Department as follows: Standard dollars, $568,272,478; subsidiary coins, $185,293,874; total, $753,566,352. Of the standard dollars $493,459,000 are held in the Treasury against silver certificates outstanding.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—July 10

The base price paid this week for 60% zinc ore was $100@110 per ton. The base price paid for 80% lead ore was $70 per ton.

SHIPMENTS WEEK ENDED JULY 10

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	2,819,400	371,580	475,380
Year	97,973,430	3,888,470	14,261,270

Shipped during week to separating plants, 3,582,000 lb. zinc ore.

The net shipment of finished ore for the first six months of 1915 showed a gain of 18,513,630 lb. over the corresponding period last year.

JOPLIN, MO.—July 10

Blende, high price $112; base per ton of 60% zinc, premium ore $110, medium to low $105@90, in car lots. Calamine base per ton of 40% zinc, $58; average price, all grades of zinc, $100.01. Lead, high price $72; base $70@60 per ton of 80% metal content; average all grades of lead, $61.47 per ton.

SHIPMENTS WEEK ENDED JULY 10

	Blende	Calamine	Lead	Values
Totals this week	4,814,370	185,580	1,335,420	$291,090
Totals this year	303,970,400	26,144,080	46,101,670	12,667,270

Blende value, the week, $245,030; 28 weeks, $10,905,980
Calamine value, the week, $5030; 28 weeks, $550,310
Lead value, the week, 41,030; 28 weeks, 1,210,980

Production of the Missouri mines in the district was not over 800 tons. The miners are now gradually returning to work and the strike is almost over.

OTHER ORES

Chrome Ore—The latest quotations in London are, per long ton: New Caledonia ore, 50% base, $27.60 per ton, with a scale of 60c. per unit for variations. Rhodesia ore, base 48%, $26.40, variation 48c. per unit. Baluchistan ore, base 50%, $27.60, variation 60c. per unit. New Caledonia and Baluchistan ores generally run over 50%; Rhodesia 2 to 3% below.

Iron Trade Review

NEW YORK—July 14

Activity continues in the iron and steel trades, largely due to the volume of export business placed, but in some degree also to improving consumption at home.

The rate of operations at the steel mills has increased, and some of them are working well up to capacity. The Steel Corporation June report of orders shows that its new business for the month must have exceeded deliveries by a considerable amount. The Corporation is now reported to be buying billets from outside mills to supply some of its plants in the East.

Pig iron seems to linger behind. The increase in production shown this month is mainly from the steel works furnaces, the merchant stacks having only a small gain.

Holding that tariffs filed by 11 railroads proposing charges for hauling slag from furnaces in western Pennsylvania, Ohio and West Virginia, do not conform to the act to regulate commerce, the Interstate Commerce Commission has handed down a decision ordering the tariffs stricken from its files. The commission says, however, it sees no reason why this disposal service must be performed gratuitously by the carriers. It makes it plain that it expects the railroads to file appropriate tariffs conforming with other requirements attending business of common carriers. These tariffs are expected to be regular and be more specific than those which were on file.

Exports from Baltimore for the week included 2,703,610 lb. billets and skelp steel; 3,466,919 lb. bars and wire rods; 2,631,730 lb. wire and 3,330,949 lb. pipe, all to Great Britain.

Pig Iron Production—The reports of the furnaces on July 1, as collected and published by the "Iron Age," show at that date 218 coke and anthracite stacks in blast, having a total daily output of 80,400 tons; an increase of 7800 tons over June 1. Making allowance for the charcoal furnaces the total make of pig iron in the United States in June was 2,408,500 tons; for the six months ended June 30 it was 12,248,400 tons. Of this total 8,960,700 tons, or 73.2%, were made by the furnaces owned and operated by steel companies. Production now is at the rate of about 29,500,000 tons yearly.

Exports of Iron and Steel for which weights are given in the returns amounted during May to 138,514 tons in 1914, and 262,814 in 1915; an increase of 124,330 tons, or 89.8%, this year. The larger gains were in bars and wire rods, billets and ingots, plates and wire.

PITTSBURGH—July 13

Conditions in the steel industry seem to be improving even more rapidly this month than they did in May and June, a remarkable showing considering that July and August are usually dull months in the industry. Bookings by the steel mills have been heavy thus far this month, comparing very favorably with June, and prices are stiffening more or less practically all along the line, even including such items as railroad spikes, chain, shafting, rivets, etc., which are usually slow in showing price advances.

The pig iron and coke markets have become excited and there are predictions of almost sensational price advances. The pig iron market, however, is quite unsettled, on account

of the Lake front furnaces presenting such unusual competition with the Valley furnaces.

The Steel Corporation's contract obligations are reported at 4,678,196 tons at the close of June, showing an increase of 413,598 tons during the month, against a gain of 102,354 tons in May and small losses in April and March. The June increase was equal to about one-third of capacity, while the shipments were about 80% of capacity, so that bookings exceeded capacity by a wide margin.

The bi-monthly wage adjustment at the iron mills showed a realized price on bar iron shipments from the selected mills in May and June above 1.10c., giving the tonnage men in the iron mills 1 to 2% higher wages for July and August.

The steel mills are operating at more than 80% of rated capacity, and openhearth capacity is practically fully engaged, the chief idleness being in bessemer departments, and efforts are being made to divert orders from openhearth to bessemer.

Pig Iron—Two or three Cleveland furnace interests have been selling basic iron over a wider range of territory than formerly, cutting out the Valley and some detached furnaces, and $12 or less at Cleveland furnace has been done. The Youngstown Sheet & Tube Co. is reported to have bought 30,000 to 50,000 tons at a very favorable price. At the same time the Valley furnaces have advanced quotations and are holding basic at $13 and bessemer at $14 at furnace, foundry and malleable remaining at $12.75 and forge at $12.50. The freight to Pittsburgh is 95c. from the Valleys, but on account of the competition of Lake front furnaces foundry and basic seem to be obtainable at about $13.50, delivered Pittsburgh. About 50,000 tons of export bessemer are in the market, 40,000 tons being in one lot, and as copper is barred this seems to shut out eastern bessemer.

Steel—The Pittsburgh mills have been practically out of the billet and sheet bar market for weeks and now the Youngstown mills are withdrawing, being well sold up, at least on openhearth. Consumers in general are well covered by contracts, but odd lots inquired for are drawing higher quotations right along. We quote: Bessemer billets, $20; bessemer sheet bars, $20.50; openhearth billets, $21; openhearth sheet bars, $21.50, f.o.b. maker's mill, Youngstown, the market delivered Pittsburgh being $1 higher.

Ferromanganese—The situation seems to be a shade easier, as contracts are more readily accepted at the regular price, $100, Baltimore, and prompt lots can be picked up at $100@105, Baltimore.

IRON ORE

Lake shipments of iron ore from the Lake Superior region in June were 6,005,091 long tons, an increase of 502,724 tons over June, 1914. From the opening of the season to July 1 the shipments by ports are reported by the Cleveland "Iron Trade Review" as follows:

Port	1914	1915	Changes	
Escanaba	1,076,020	1,248,830	I.	172,810
Marquette	383,948	547,002	I.	163,054
Ashland	883,081	1,161,792	I.	278,711
Superior	3,733,502	1,777,600	D	1,955,902
Duluth	1,779,876	4,295,811	I	2,515,935
Two Harbors	1,767,689	2,490,248	I	722,559
Total	9,621,116	11,521,283	I	1,897,167

The increase from Duluth and the decrease from Superior are due to the termination of the Hill leases.

Sales of local iron ores to Eastern furnace have about reached the capacity of the mines. Foreign ores are nearly cut off by the ocean freight situation. This will probably result in increased sales of Lake ore in the East.

Imports at Baltimore for the week included 6490 tons of manganese ore from Brazil.

SAULT CANAL TRAFFIC

The total tonnage of freight passing through the Sault Ste. Marie Canals in June was 8,360,832 short tons, 7,990,390 tons using the American and 370,442 the Canadian Canal. For the season up to July 1 the total tonnage was in short tons: East bound, 13,006,133; west bound, 4,138,001; total, 17,144,134 short tons, an increase of 299,417 tons over 1914. The total number of vessel passages this year was 2581, showing an average cargo of 3075 tons.

The mineral freights included in the totals were as follows in short tons, except salt, which is given in barrels:

	1914	1915	Changes	
Anthracite	702,339	678,852	D	23,487
Bituminous coal	4,038,630	3,022,437	D.	1,016,253
Iron ore	9,112,500	11,072,607	I.	1,960,017
Pig and m'f'd iron	128,388	75,205	D.	53,183
Copper	18,287	41,272	I.	22,985
Salt, bbl.	343,204	232,173	D	111,031

Iron ore was 64.6% and coal 21.6% of the total freight reported this year.

COKE

Coke production of the Connellsville region for the half year to June 30, 1914, is reported by the "Courier" at 7,336,643 short tons; shipments, 7,310,855 tons. Production of the Greensburg and Upper Connellsville district for the half-year was 923,665 tons.

The U. S. Geological Survey estimates the production of bituminous coal in the United States in the first half of 1915 at about 185,000,000 short tons, a decrease of 10% from last year.

Connellsville—Operators have stiffened materially in their views, chiefly on account of better prospects in pig iron and steel, and instead of quoting $1.75 on contract furnace coke for the second half are quoting $1.75 for July or third quarter, and $2 for the half year. On a flurry caused by fear of insufficient supplies over the national holiday spot furnace advanced from $1.50 to $1.75, but has now receded only to $1.60. Foundry remains at $2@2.40 for prompt and $2.20@2.50 for contract, per net ton at ovens.

Anthracite Shipments in June were 5,316,102 long tons, a decrease of 814,084 tons, as compared with June, 1914. For the six months ended June 30 the shipments were 32,945,789 tons in 1914, and 31,595,304 tons in 1915; a decrease of 1,350,485 tons, or 4.1%, this year.

British Fuel Exports, five months ended May 31, in long tons:

	1914	1915	Changes
Coal	28,852,713	18,775,284	D. 10,077,434
Coke	444,446	366,996	D. 77,450
Briquettes	852,326	509,471	D. 342,855
Steamer coal	8,500,680	6,334,542	D. 2,166,138
Total	38,650,170	25,986,293	D. 13,663,877

The total decrease was 35.3%, and was due entirely to war conditions.

Chemicals

NEW YORK—July 14

General market conditions have not materially changed. In some lines there is a good deal of activity, but others remain rather quiet.

Arsenic remains quiet but steady, with supplies sufficient for the demand. Quotations are steady at about $4 per 100 lb. for both spot and futures.

Copper Sulphate—The market shows a good demand and prices are steady at $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller parcels.

Nitrate of Soda continues in good demand and the market is strong and steady. Current quotations are firm at 2.35c. per lb. for spot and for all positions this year.

Potash Salts—U. S. Consul T. J. Albert at Brunswick, Germany, reports that the German market for potash is weak for this season of the year. It is hoped that the demand for manure salts will be more active in the fall and that difficulties of railroad transport will not again occur. The ocean export to foreign countries has ceased, since the Government issued its decree forbidding such export. Shipments to Austria-Hungary were not affected by the decree, and shipments to the Scandinavian countries and the Netherlands are allowed. On the other hand, shipments to Italy have been limited. The value of the exports of potash for the first four months of the present year amounted to $8,277,650, as compared with $11,840,403 for the same period in 1914. The decrease in the month of April was $1,230,609 as compared with April last year.

Pyrites—Imports at Baltimore for the week included 6887 tons of pyrites from Huelva, Spain.

PETROLEUM

Exports of mineral oils from the United States in May were 225,254,580 gal., or 30,303,984 gal. more than in May, 1914. For the five months ended May 31 the total exports were 803,071,386 gal. in 1914, and 866,456,249 gal. in 1915; a decrease of 36,615,137 gal., or 3.9%, this year.

The London "Petroleum Review" says that the latest information available is that the situation on the Galician oil fields is very serious. The whole of the remaining staffs have hurriedly left the oil-field region, many of them now being in Lwow. According to the "Pester Lloyd," the stocks of oil on the fields and at the refineries have been destroyed, while a fire which has been raging round Boryslaw-Tustanowice for several days has completely destroyed the majority of the derricks. It is reported that practically every operating company in the fields has suffered very considerable damage to its property.

Arizona Copper Co.'s Dorr Thickener

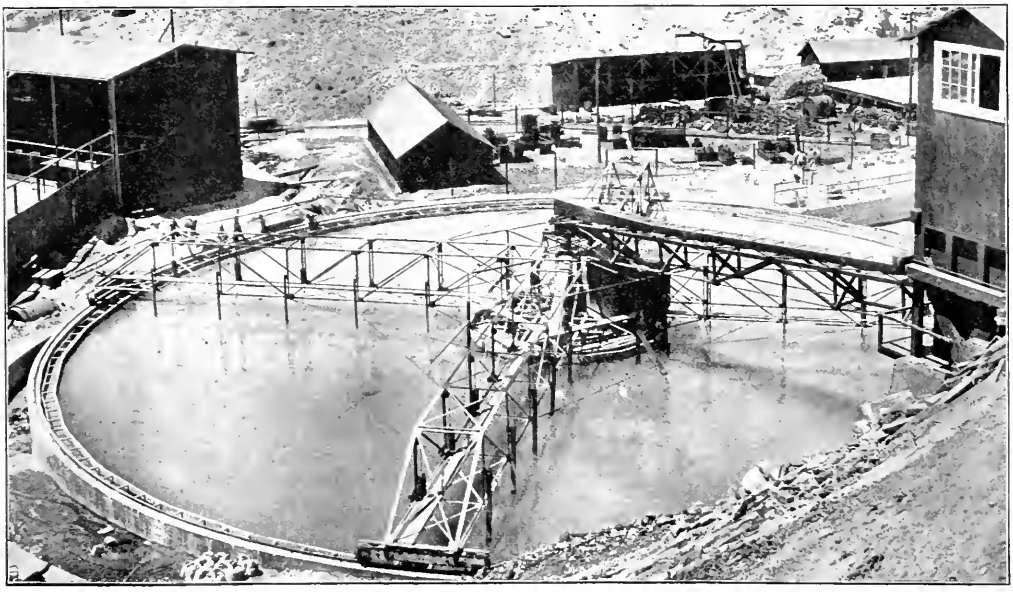
By David Cole*

SYNOPSIS—The largest Dorr thickener ever constructed, 130 ft. in diameter, is used to recover water from the tailings of the concentrating mill. The tank is built of concrete, with a central pier and a peripheral track for sustaining the trusses which carry the scrapers. The operation of the machine has been entirely successful.

All of the milling in the Clifton-Morenci district was primarily done in the drainage area of Chase Creek on rough ground so situated that the tailings would gravitate into the San Francisco River, which empties into the Gila within a few miles of Clifton.

On the Gila, below the mouth of the Frisco, a prosperous farming community has grown up, using the river water for irrigation purposes, and as the irrigation system became more fully developed and all of the low-stage water of the Gila used, the tailings became a menace to the operations of the farmers. Realizing this, the mining companies constructed impounding dams, but on account of the long drainage areas above them, and the precipitous ground upon which they were built, these dams could not be sufficiently protected against floods. A serious break in 1906 brought the matter into the courts and the companies were forever enjoined from allowing any of the tailings to enter the streams.

The Detroit Copper Mining Co. found it feasible to tunnel a small divide and, by using a long flume suspended on the sides of a cliff, reach suitable ground in the drainage area of Morenci Cañon, upon which the tailings could be successfully impounded; but the Arizona Copper Co.'s No. 5 mill was not so favorably situated and this company found it necessary, in order to reach suitable ground upon which to deposit tailings, to move its milling operation to Morenci. Since the mill and mine would then be close together it was decided to fill the square-set stopes of the



ARIZONA COPPER CO.'S DORR THICKENER

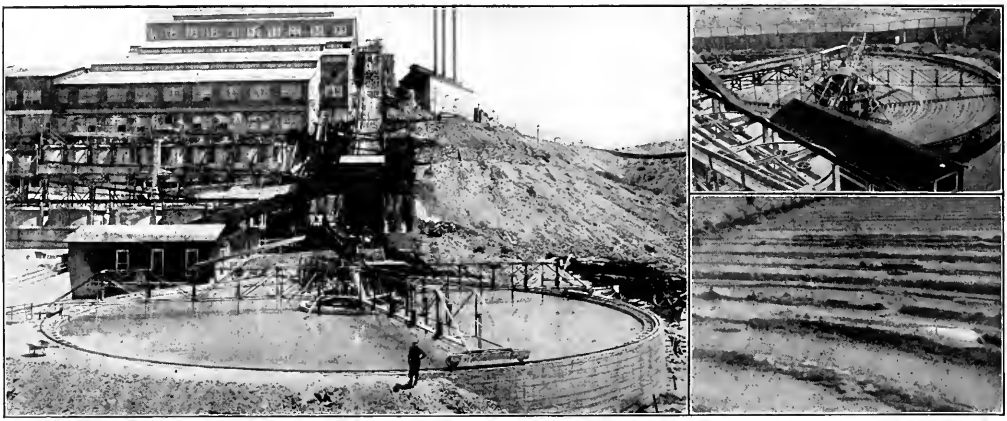
*Consulting engineer, Arizona Copper Co., Morenci, Ariz.

Longfellow mines with the coarsest part of the sand tailings made at the mill, and the large circular tank, which has now been transformed into the largest Dorr thickener and is the subject of the following remarks, was constructed as part of the apparatus devised for reclaiming the sands.

The tank is 130 ft. in diameter and 10 ft. deep, and is divided into several compartments so that one can be emptied while the others are filling. A hollow pier 21 ft. in diameter was constructed in the center of the tank, and a powerful revolving electric crane with long boom and grab bucket was put upon this pier and used for dipping out the sands and delivering them to the skips provided for hoisting the product to the mine level. It was soon discovered that the wet tailings were not good in the mine, and that earth embankments on the tailings ground made poor as well as expensive dams in which to impound slimes, and that the value of the sands in the construction of the tailings dams outweighed their value as filling material. So the electric hoist was removed from the pier and the round tank was arranged with a bottom as illustrated by the accompanying photographs, which show clearly the method of construction and how the thickener appears when in operation.

No trouble has been experienced with it, and although it has been in steady operation for more than a year, the repairs have been exceedingly small. The valves were originally made 8 in. in diameter, with a 3-in. plug opening in each. It was found advantageous to change these valves so as to make the openings 3 in. and dispense with the continuously spouting plug. The new 3-in. valves were arranged to have ball instead of flat seats, and bronze is used instead of old belting for the contact parts. These valves are opened intermittently and are controlled by cams which are adjustable as to number and period. The drive was originally by chain, but this was noisy and otherwise undesirable, and since it developed that a belt would have ample traction, the chain was changed to belt drive.

The rabbles are carried on 3x10-in. fir stringers and these are suspended from the bottom of vertical members hinged at their top ends as shown in drawings, and are

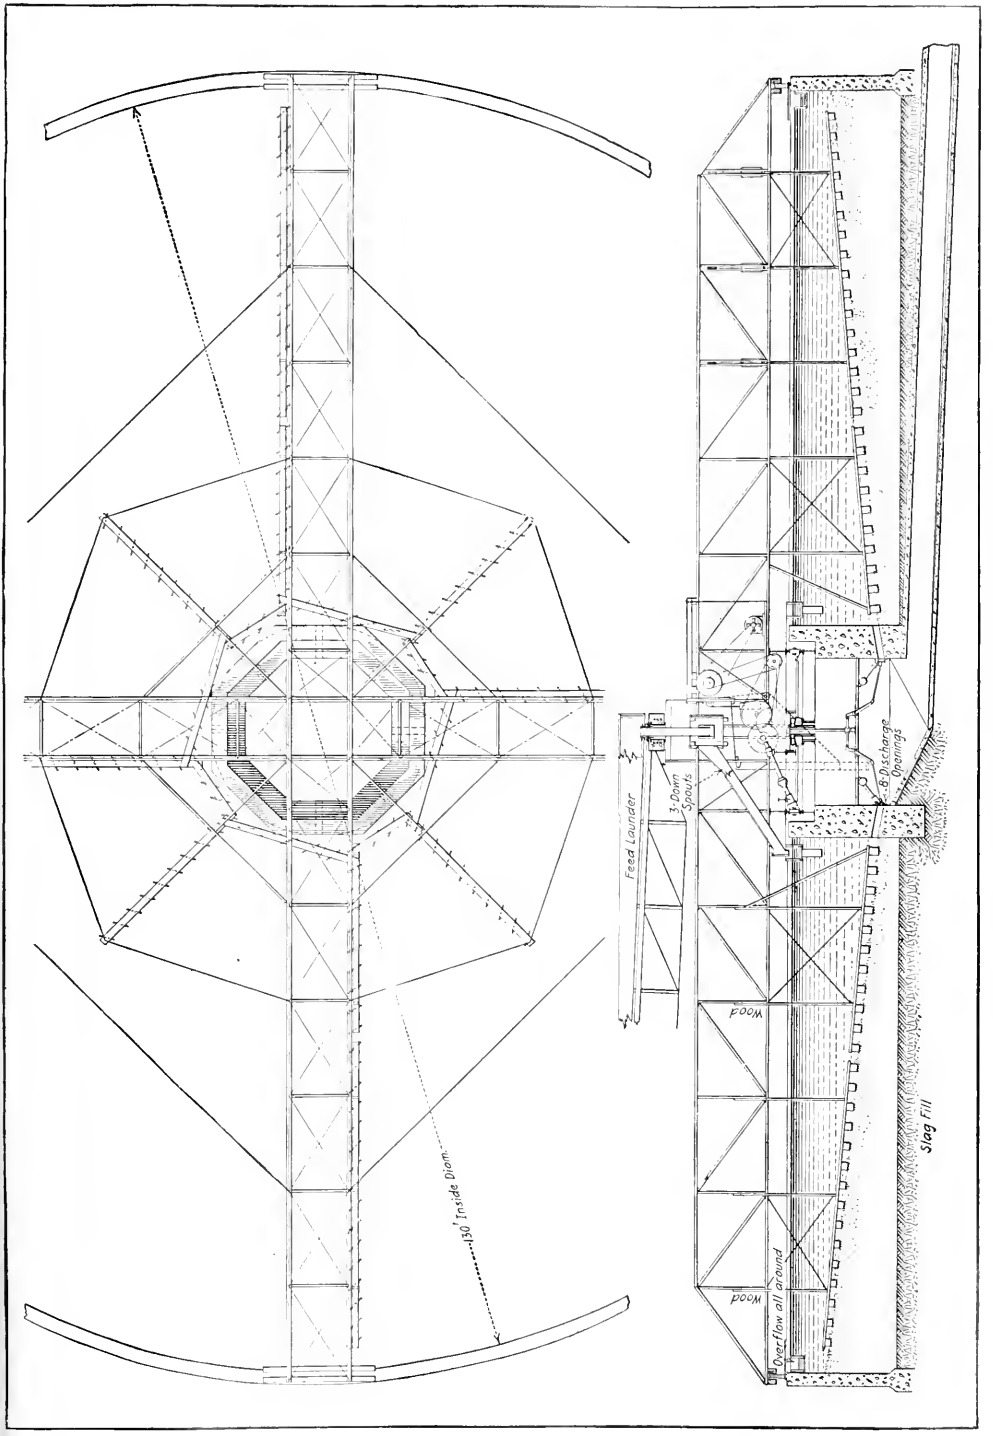


SITUATION OF THE THICKENER WITH REGARD TO THE MILL
The two smaller views show the thickener empty and illustrate the rake action

cut up into V-sections with a multitude of valves communicating with a drainage-pipe system, which did not meet expectations for reasons that are now entirely obvious.

In the work of remodeling and enlarging the milling plant, recently completed, I decided that the large circular tank could be made most useful by converting it into a Dorr thickener. It seemed rather bold to attempt one so much larger than had previously been tried, but conditions were favorable. It would be possible to use the central pier to advantage; the machinery provided for carrying the crane would carry the mechanism of the thickener; and much of the old crane framework and gearing could be used. There was a good T-rail around the rim of the tank to support the outer ends of the cruciform bridge required, etc., so the plans were drawn and the matter laid before Mr. Dorr, who was inclined to hesitate a little at first, but on further study decided that it was a splendid chance to try out the new questions involved, so we bought a nameplate of him, conditioned on the success of the "leviathan," and carried out our plans held back by using copper guy-lines with weights so that in case a rabble-arm should be caught or offer too much resistance, the weight would be raised and the arm would pass the obstruction through the operation of the hinge provided. This now appears to be unnecessary, for, in our experience, the vertical members have never moved from their seats against the trusses. A Reeves variable-speed countershaft was made part of the driving mechanism and experiments were made with several speeds. They all worked satisfactorily, but we finally settled upon one revolution in 30 min. as best for our work. There is little difference between two and three revolutions per hour in the results obtained.

The heavily reinforced-concrete wall of the tank was built upon a slag dump, which is substantial but notoriously porous. Sand tailings quickly sealed the bottom and the hardening slimes finished the job, so that there is no loss of water through seepage. It will be noted that since the bottom of the old tank is flat and the bottom maintained by the rabbles in the thickener is sloping, there is a deep deposit of slime near the outer wall afford-



DETAILS OF ARIZONA COPPER CO.'S DORR THICKENER AT MORENCI, ARIZ.

ing a good surface sloping toward the center with about 2 ft. of hardened deposit on top of the slag around the central pier. So it is at once suggested that these lines might be extended; the upper end of the slope of the cone rim could be extended to where it would be within one foot of the surface, and the central hollow pier could be decreased in size to, say, 10 ft. inside diameter, equipped to discharge the tank in the same way. Then a circular track supported by a small circular wall at the water's edge on the outer rim would support the light truss members of the cruciform bridge. The trusses would be tied together so as to move in unison and the tractive force would be applied on the outer circular track through wheel friction, the same as in railroad practice. The hollow central pier would be connected by large tile or reinforced-concrete conduit to a point of discharge outside of the rim. This may be a pit fitted with centrifugal pump or elevator for raising the discharge to sufficient height so that it may be handled to its destination by gravity. In this way Dorr thickeners up to 200 ft.

STATISTICAL DATA OF THE DORR THICKENER

Diameter of settling pond	130 ft.
Outer depth	4 ft.
Inner depth	8 ft. 6 in.
Diameter of pier (octagon)	21 ft.
Revolutions per hour	2-3
Number of 3-in. discharge valves	8
Number of rabble arms (4 long and 4 short)	8
Size of motor	5 hp.
Size of discharge conduit (to allow man to go in.)	2 ft. 6 in. by 2 ft. 6 in.
Settling area	13,000 sq.ft.
Average feed (tons dry colloidal slime per 24 hr.)	700
Average per cent. solids in feed	5.93
Average per cent. solids in discharge	30.65
Water recovery	85.75%
Gal. recovered per min. (approximately)	1,700
Power required (motor input)	4.7 hp.

Moisture in the discharge can be reduced to 50%, but the tailings are flumed two miles, for which reason the discharge is not made thicker.

in diameter or more can be installed on suitable ground at relatively small construction expense, and such machines should have large capacity, require little power and be cheaply maintained, thus giving the maximum results with the minimum expense.

It is, of course, much more expensive to house the large-diameter machines than the multiple units, but I believe that the large units consisting of relatively shallow ponds with conical bottoms built in the earth would be very readily kept from freezing by the application of the heat to the solutions being handled instead of to the air in contact with the solutions. I believe that less heat would be required by applying it in this way, and when so applied I believe that open-air construction and operation would be best, even in the North. Extremely large ponds should be fenced to break the force of the winds, otherwise a wave action is set up which interferes with settling to some extent.

The full capacity of our big thickener has not been determined. It discharges as much water as the electric pumps provided will handle, and if more feed is given the thickener, water would run to waste. Since this water has to be pumped seven miles against a pressure of nearly 1800 ft., it is expensive, and therefore carefully husbanded.

I have every reason to believe that with tailings as coarse as 40-mesh sand—when the coarse sand is not in larger volume than, say, 30% of the whole—the capacity in terms of tons handled would be found to be greatly augmented, nearly doubled, in fact. The amount of water clarified is, of course, dependent upon the percentage of colloidal material in the feed to the machine. Thus, much additional solids in the form of sands could be added to the present tonnage of real slime without changing any of the prevailing conditions except to greatly augment the tonnage handled.

In our case the man in charge of the pumping station oils the thickener and adjusts the cams controlling the discharge valves occasionally. Practically no labor is required.

Low Cost of Maintenance

The repairs required for 14 months' operations, including the changes mentioned above, are represented in a total sum of $682, which is 0.2c. per ton of dry solids handled in the period. Most of this expense is for valves destroyed by the water handled.

When the war broke out milling was reduced to six days a week and the thickener was stopped on Saturday night and started again Monday morning, and on one or two occasions the machine has stood idle for 48 hr., but it has always started again without difficulty of any kind and without lifting the weights which hold the rabble stringers against their seats.

There has been much interest manifested in the big thickener, and I had hoped to arrange temporarily feed- and water-handling facilities so that tests could be made definitely to determine the capacity, or range of capacities with different classes of feed, before writing a description of the apparatus; but this has not been possible. The extra recovery of water resulting from the use of the large thickener returned its cost in less than two months. It has therefore been highly successful and advantageous.

Dimensions, Weights and Costs of Steam Turbines*

Tables 1 and 2 were compiled from data supplied by manufacturers and should prove of value in connection with preliminary estimates. The dimensions, weights and cost data are for condensing units and include the turbines and alternating-current generators.

The values in Table 2 were plotted and the following equations were deduced, giving the cost in dollars (C) of the turbine and generator, in terms of the capacity in kilowatts:

Impulse types, C = 5040 + 9.2 kw. (Dollars)
Reaction types, C = 7400 + 8.26 kw. (Dollars)

Orebodies of the Mesabi Range—II

By J. E. Wolff*

SYNOPSIS—Vertical sections through developed orebodies from different parts of the range illustrate relations existing between orebody and unaltered iron formation; rock walls; "horses" and "islands"; faults; folds; the slump and other structural features. Western Mesabi orebodies differ in some points of structure, notably in the absence of slump.

Following the discussion of typical structure in Part I, there may be taken up some actual illustrative examples in the form of vertical sections through orebodies from various parts of the Mesabi range, including the sandy ores of the western end.

Figs. 11 to 16 inclusive show sections of orebodies actually developed in different parts of the range by drilling and mine workings. Some of the bodies are nearly worked out at the present time. The sections taken transverse to the long axis of the orebody, that is, across the trough, show the slump markedly; those taken along the axis of the trough do not show it. All of the sections show the typical structure illustrated in Figs. 6 and 7 (Part I).

Fig. 11 shows the cross-section of an orebody now partly worked out. The marked slump and sharp rock walls are features actually observed in the mine. Some idea of preglacial erosion of the taconite, and of ore also, can be formed by comparing this section with Fig. 6. A thickness of 350 ft. to 500 ft. of taconite has been eroded.

Fig. 12 shows two troughs separated by taconite. West of this cross-section these two troughs connect into a larger orebody. An anticline and syncline in the quartzite are shown. This was worked out from drill holes not occurring on the cross-section. Close study of drill records has disclosed many such minor flexures of the formations. Attention is called to the lower nonbessemer ore extending to the south under taconite. This is a characteristic flat-layered body, mentioned before. More frequently the ore occurs immediately below the Intermediate slate layer (Fig. 20).

Fig. 13 shows a cross-section of an orebody now nearly mined out. Notable features are the sharp rock walls, as actually defined by mine workings, and rock layers and horses or pillars in the lower blue orebody. Preglacial

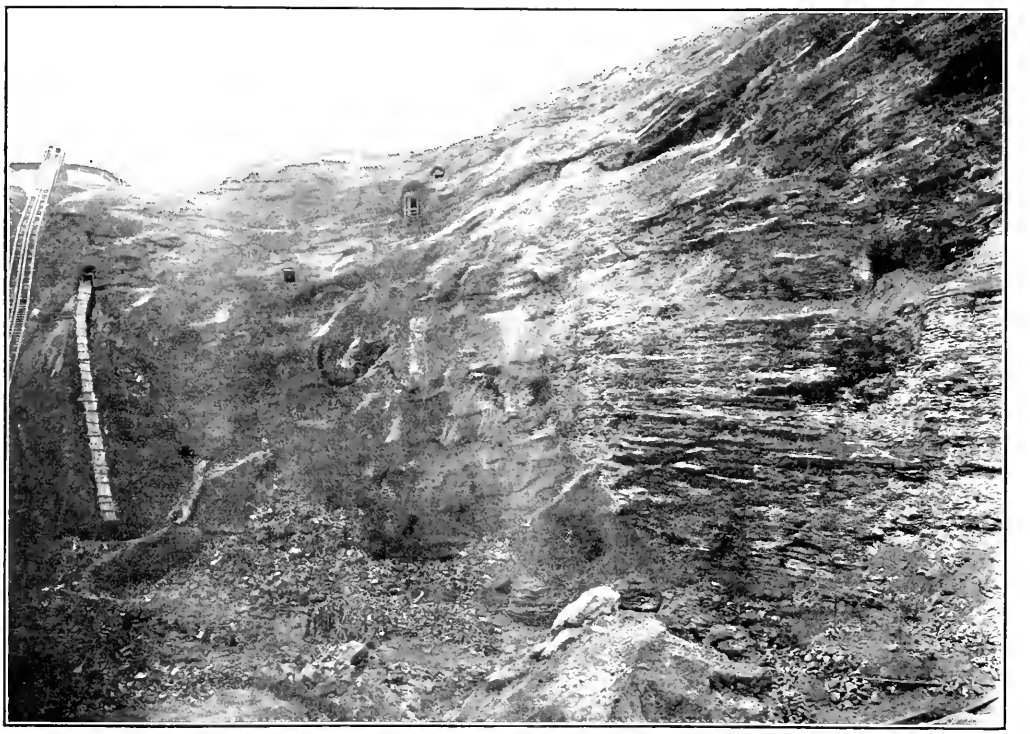

FIG. 8. SHARP ROCK-WALL OF A DEEP TROUGH OREBODY ON THE EAST CENTRAL PART OF THE RANGE
Note face of wall. Left half of picture shows ore

*Mining engineer, Oliver Iron Mining Co., Duluth, Minn.

erosion is marked here also. Note the slump at the rock walls and on both sides of the "taconite island." In connection with this compare Figs. 8 and 10.

Fig. 14 is a cross-section of an orebody of which the east wall is an altered granite dike. In places some concentration was found by mine workings east of the dike also. Samples of the dike assayed 3.65% titanium, which is practically unknown in the iron formation proper.

Fig. 15 is a section transverse to the length of an orebody but does not show the slumping feature except at its south rock wall, because of the steep dip of the formation. Attention is called to the ore "making" under the Virginia slate. This orebody with its eastern continuation is one of the few in which this condition is known to exist. In this body one drill hole showed ore to a depth of 900 ft., the deepest known on the range. This cross-section will be referred to later in connection with the fault shown by Fig. 17.

Fig. 16 shows a longitudinal section of a typical Western Mesabi washable orebody. A comparison of this section with any of the foregoing shows their analogous structure. A transverse section of a Western Mesabi orebody but does not show the sharp rock walls or marked slumping observed in bodies in the central and eastern part of the range. The western bodies are shallower than the central and eastern. In the western bodies the silica has been leached out of the taconite and the iron well oxidized and concentrated into seams and layers; the silica, however, has not been transported but remains as extremely fine, almost impalpable, white powder. This is the condition in both upper and lower blue orebodies. The upper slaty taconite becomes altered in a washable orebody to decomposed taconite which yields a fairly good product after being washed. The lower yellow taconite alters to an extremely sandy washable ore. The upper 10 ft. of this layer contains so much silica and so little ore as to be worthless by itself as washable ore; it resembles common building sand. The upper and lower blue ores in a washable orebody are known as typical washable ores. The silica separates easily from the pieces of hard hematite and the problem of concentration is a simple one.

From the sections presented, covering all parts of the range, it is evident that the same structure exists from one end to the other. Structurally the range and its orebodies are remarkably uniform. The same structure as here shown can be worked out for any orebody if drill and mine exploratory work and records are complete enough. This matter will be discussed more in detail in Part III.

Fig. 17 shows a normal fault with a throw of 200 ft. or more in which the quartzite and underlying greenstone have been faulted up against the orebody. This fault is the eastern continuation of the Biwabik mine fault, the throw of which is probably 300 ft. or more. It goes off west into the underlying rocks just north of the Duluth mine (NW ¼ of NE ¼, Sec. 3, T. 58 N, R. 16 W). Eastward it dies out before it reaches Embarrass River and gives way to a steep inclination of the formation, as shown by Fig. 15, a cross-section east of this river. Thus it is a fault of the hinge type. This fault and the steep dip are the cause of the quartzite tongue on the geological map in Secs. 33 and 34, T. 59 N, R. 15 W, and the sharp bend in the formation at this place. The deformation produced an anticline in the iron formation and the quartzite. Erosion truncated the series, exposing the tongue of underlying quartzite and the bend in the formations.

Fig. 18 shows a thrust fault in the Alpena mine, a mile north of the city of Virginia. This is the greatest known fault of the Mesabi range. The stratigraphic

throw is 350 ft., and the vertical throw at least 600 and possibly 1000 ft. This fault is visible in the Sliver mine, north of the Alpena, and has been traced by explorations a half mile south of the Alpena. Fig. 19 shows the probable development of this fault. Its development is directly related to the folding or deformation which produced the large bend in the iron formation between Virginia and Eveleth, known as the "Virginia horn." This deformation is a big drag-fold. The sharp bend in the iron formation northeast of Virginia caused compression and consequent crumpling in the layers of the formation, and necessitated shortening somewhere. The shortening took place in this fault. Diagrams *A*, *B* and *C*, of Fig. 19, show the development of this fault. As the deformation started to develop the Virginia horn, a small drag fold developed as shown in *B*, thus shortening the layers in response to the compression in them. (It is a well established fact in structural geology that in a folded formation the small folds are of the same type as the large folds upon which they are superimposed.) As the deformation increased, the brittle quartzite and iron formation faulted on a plane through the axis of the small drag fold, into the position shown by *C*. Erosion has since cut the top of the fold as shown. Without doubt the fault continues down into the underlying rocks, slates and greenstone. The fault occurred prior to the formation of the orebody, as along the fault plane there is no evidence of movement in the layers of ore. Along the east side of the taconite island (Fig. 18), at the contact of rock and ore, is found a layer of powdered silica several inches thick. This was the fault plane and this powdered silica was produced by the rubbing of the broken taconite in the faulting process. Some slipping within the beds of iron formation undoubtedly occurred also. The fault probably occurred during Upper Huronian or not later than Keweenawan time. It is a fair assumption that the deformation which caused the Virginia horn, the Alpena fault, the Biwabik fault and the steep dip of the formation east of it, was contemporaneous with the intrusion of

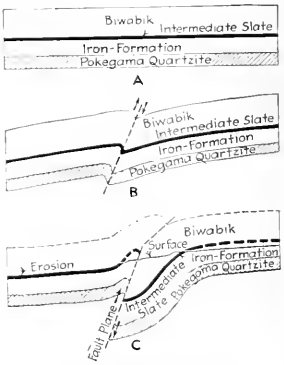

FIG. 19. FAULT DEVELOPMENT

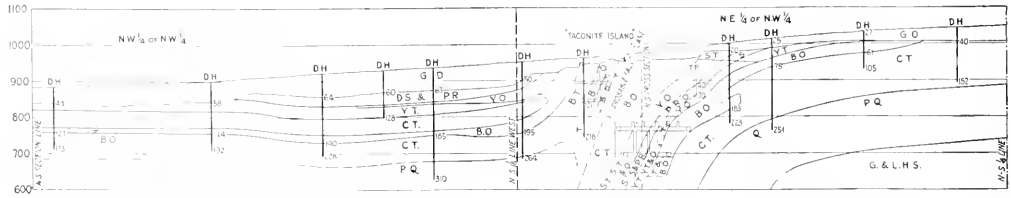

FIG. 18. SECTION LOOKING NORTH, SHOWING FAULT IN ALPENA MINE. N. ½ OF N.W. ¼, SEC. 5-58-17

Keweenawan time. It is a fair assumption that the deformation which caused the Virginia horn, the Alpena fault, the Biwabik fault and the steep dip of the formation east of it, was contemporaneous with the intrusion of the Embarrass (Keweenawan) granite and the Duluth (Keweenawan) gabbro.

Fig. 20 shows a cross-section of an orebody in which the whole formation is bent into a sharp monoclinal fold. This fold was worked out entirely from the drill records; it was followed for a half mile each way from the cross-section. The orebody beneath the Intermediate slate, or paint-rock layer, is a typical example of a flat-layered orebody. A thousand feet north this ore connects with a large trough orebody similar to that shown by Fig. 12. The ore above the Intermediate slate connects each side of the cross-section with elongated bodies of ore. The conglomerate at the top of the iron formation is not Cre-

taceous; it is later in age and the pebbles are not cemented together as in a Cretaceous conglomerate. It is probably a bed of iron pebbles deposited in a local, preglacial lake on top of the iron formation. Numerous occurrences of the kind have been found in drilling and mine operations.

Other exceptional structural features are known in different parts of the range. In the Hawkins and La Rue orebodies at Nashwauk in T. 57 N. R. 22 W. there is a marked faulted fold, which, by means of drilling, has been followed in the taconite between the two orebodies. At the north end of the Agnew mine (NE ¼ of NE ¼, Sec. 11, T. 57 N. R. 21 W), the face of the ore on the Hull forty shows a small faulted drag-fold in the middle of the trough of the orebody (Fig. 3, p. 91). In the Graham mine (Sec. 21 T. 59 N. R. 14 W) on the eastern end of the range, a fold extends the length of the orebody. It is a thrust fold, the south side being thrust up undoubtedly by the great gabbro intrusion 1¾ miles southeast. As the top of the fold is eroded it is not possible to tell how close the fold was.

(To be continued)

Domestic Sulphur Consumption

The sales or marketed production of sulphur in the United States in 1914, according to the Geological Survey, was 327,634 long tons, valued at $5,954,236. These sales were the largest in the history of the industry and 16,044 long tons greater than those of 1913. The sulphur mined in 1914 but stocked at the mines is not included in these figures. In 1914 four states produced sulphur, namely, Louisiana, Texas, Nevada and Wyoming. [One company in Louisiana alone produced more than the total consumption in the United States, as it has done for several years past.—Editor.]

The total imports for 1914, entered for consumption, were 26,135 long tons, valued at $477,937, of which 23,610 tons, valued at $398,984, were crude sulphur. Corresponding figures for 1913 were 22,605 long tons, of which 15,122 tons were crude sulphur. In 1914 the great bulk of the imports was, as usual, from Japan.

In 1914 the exports were 98,153 long tons, and would probably have been considerably greater but for the disturbed conditions in Europe. Even with such adverse conditions the excess of exports over imports amounted to 72,018 long tons, the balance of trade in favor of the United States being $1,329,397.

Ore Reserves of the Rand

By A. Cooper Key*

The table presented herewith shows the quantities of payable ore reserves at the principal Rand mines at the end of last year, or the latest figures available in certain instances where the company's year does not correspond with the calendar period, as well as at the end of 1913. The method of expressing ore reserves varies somewhat among different groups and engineers. For instance, there are stoping tons and milling tons, the latter not frequently. There is considerable difference between the two, and sometimes insufficient information is afforded to enable the comparative significance to be grasped. It is necessary to know the average percentage of waste rock discarded. In spite of many difficulties, the ore-reserve position has been well maintained. The feature of the

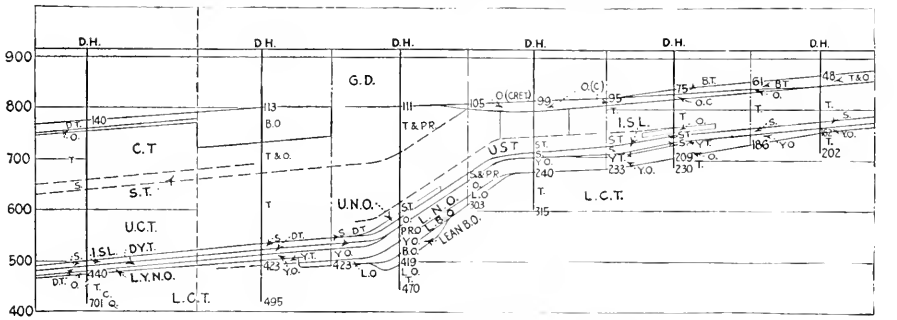

FIG. 20. CROSS-SECTION OF OREBODY IN T. 57 N, R. 21 W

table, however, is the increase which has taken place in the two mines of the far East Rand which have recently joined the ranks of producers. We have the Modder Deep and the Government Areas, each with 2,450,000 tons in sight, but the former has 8 dwt. rock against 5.8 dwt. in the latter, besides an advantage of 9 in. in the thickness of the reef. Springs Mines for the first time commits itself to an ore reserve estimate—550,000 tons of 10 dwt. rock over 52 inches.

Alone among the three big consolidations has the Randfontein Central been able to maintain its reserve aggregate. The Crown Mines' is less by 427,000 and the East Rand's by half that quantity. More serious, however, is the drop of 3s. 6d. on the valuation at the Crown Mines. Brakpan has increased its aggregate by 266,000 tons and maintained the value. City Deep has added 343,000 tons; the value is 0.3 dwt. lower, but still 1 dwt. higher than at the end of 1912. Modder B.'s value has improved by 0.3 dwt. In 1912 the New Modderfontein had 3,900,000 tons exposed; in 1913, 4,547,000; and in 1914, no less than 6,334,500 tons, the value having improved from 8.1 to 8.4 dwt. Kleinfontein gains 1,100,000 tons from the amalgamation with the Apex and Benoni, but the value is 0.7 dwt. less than that of the Kleinfontein alone a year ago. Taking Kleinfontein section by itself, the drop in value is rather greater.

Nourse Mines, Wolhuter and Village Deep are conspicuous for substantial increases, while at the City & Suburban and the New Heriot position is well maintained.

*Editor, "South African Mining Review," Johannesburg

On the west, the West Rand Consolidated has 1,800,000 tons in sight, some partially developed, which compares with 1,445,000 tons of two years ago.

The Meyer & Charlton and the Robinson share the distinction of being mines with reserves exceeding 10 dwt. The former is in the stronger position, having 105,000 tons more of definitely valued ore; moreover, the value is 59s. compared with 45s. 6d. Of course, the Charlton has a considerable life, whereas the Robinson is nearing the close of its remarkable career. By June next it will have produced £20,000,000 worth of gold, of which about £13,000,000 constitutes profit. For the first seven years of its existence the recovery was more than an ounce, sometimes more than two ounces. For the last three years it has been under 10 dwt. But working costs are now 14s. per ton against 25s. in 1898 and 35s. to 40s. in the earliest years of crushing.

Mica of Good Quality, according to U. S. Consul E. C. Baker at Chungking, is found near Shunpan, in the Szechwan Province, and one of the large Chinese firms at Chungking with a branch office in Shanghai is prepared to export this product. The price delivered at Shanghai is between 9 and 10c. U. S. cy. per lb. About 15,000 lb. can be delivered every year.

New Sampling Plant at Hamburg

A new and unique sampling plant was erected last year at Hamburg, Germany. There is a large tonnage of pyrites imported, and the plant has been erected primarily for the purpose of sampling it. The pyrites consists of hard lumps so that substantial crushing machinery is required.

The ore is imported in large steamers which discharge into lighters in one of the main harbors, whence it is conveyed inland. A certain portion of the ore is discharged from the ship into special lighters for sampling. These special sample lighters are towed to the sampling plant, which is shown in the illustration. The ore to be sampled is discharged from the lighter by means of a jib crane, as shown. The crane is provided with a self-discharging bucket which empties the ore through a trap-door in the roof of the building into a bin.

The progress of the ore may now be followed by referring to Fig. 2 which shows the layout of the plant inside the sampling building. The ore passes from the bin into a jaw crusher, which reduces it to 2-in. lumps.

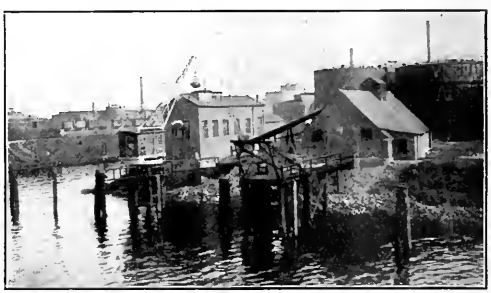

FIG. 1. SAMPLING PLANT AT HAMBURG

It then travels up a bucket elevator and through a Brunton sampler, where four-fifths of the stream is rejected. The remaining fifth goes through the gyratory crusher, which brings it down to 5/8-in. lumps; thence up a second inclined elevator to the top of a special automatic sampling machine.

It is at this point that the unique and especially interesting part of the process begins. This sampling machine consists of a large steel frame about 14 ft. high, in which are arranged three pairs of rolls. The largest, at the top, are 20 in. in diameter and the other two pairs are 16 in. and 12 in. respectively. Above the top pair of rolls and intermediate between the different sets there are three flat reciprocating vanes, or dividers, connected together and arranged to flap from side to side, so that during a portion of the time the ore striking them is diverted in one direction and during the remainder of the time in another. These reciprocating vanes will be called flaps.

The first thing that happens to the stream of ore entering the top of the machine is that four-fifths of it is rejected by the reciprocating flap *A* (Fig. 3) in the drawing. All three of these flaps are driven by cams connecting rods in such a way that during one-fifth of the time they are deflecting the stream of ore into the rolls and during the remaining time they are diverting

it out of the left-hand side of the machine. The first pair of rolls crushes the ore down to about $\frac{3}{4}$-in. lumps. This crushed product then passes over the second flap, the sample going through the second pair of rolls. After another reduction it is finally crushed to the desired degree of fineness by the last pair of rolls, when it goes through the shaking screen *B* and thence to the bottle filler *C*. If there are any particles of ore which have not been sufficiently reduced in size by the last pair of rolls, they slide off the side of the shaking screen upon a little rubber-belt elevator, which carries them up and again passes them through the final pair of rolls. In this way the whole of the final sample is crushed to any requisite fineness for the sample bottles.

One of the most interesting features of the machine is the bottle filler. This consists of a revolving table on which the bottles are placed and over them an annular hopper divided into compartments so arranged that a certain portion of the final sample is diverted and fed into the bottle in such a way that a definite quantity goes into the bottles and each bottle gets its correct proportion. Another feature of the machine is the provision of automatic adjustable feeders between the sets of rolls for keeping the stream of ore practically uniform. When each set of bottles is filled it is immediately removed, corked and sealed by the representatives of both parties.

The rejects from the plant are all discharged on an inclined belt conveyor, which carries them out through the side of the building and up to the top of an adjacent one, shown at the right of Fig. 1, the left-hand structure in that photograph being the sampling building proper. Probably this is the first time that a machine combining in itself complete crushing and sampling-plant functions has been built. The building containing it is of simple construction, carries only one line shaft and does not have to support any machinery whatever, the latter being set upon foundations on the ground. From careful tests made the results obtained have been extraordinarily accurate, with only a minute difference in the analyses from different bottles filled at the same time by this machine and representing the same parcel of ore.

Before this plant was installed the work in Hamburg was done in a semi-automatic plant consisting of two crushers and a set of rolls, the ore being coned and divided by hand, by the old method, between crushings. One tub in every 15 was taken from the ship and put through this plant, and carrying on the process in this way it took 7 men in the plant working about 14 days to get through the sampling of a 5000-ton cargo. With the new plant the same operation is performed in 3 days by 3 men. The whole plant is driven by a 65-hp. motor, the normal load of which, however, is only about 40 horsepower.

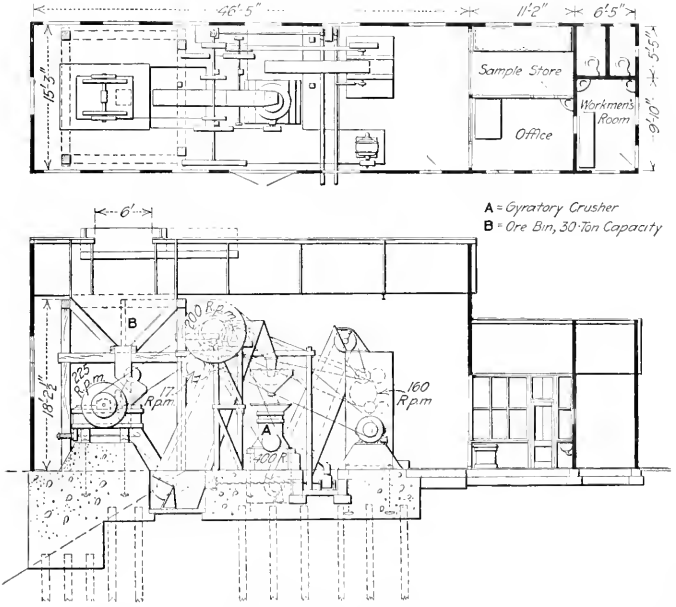

FIG. 2. ARRANGEMENT OF THE SAMPLING PLANT

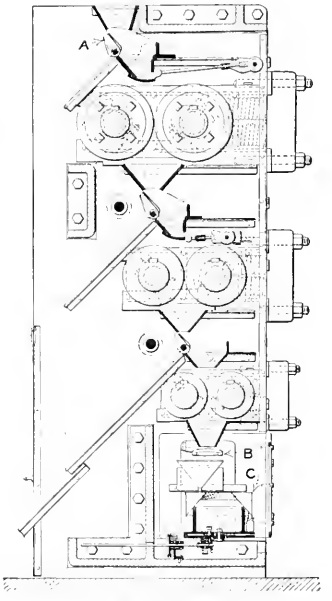

FIG. 3. SAMPLING MACHINE

Negligence of Co-Employees

By A. L. H. Street*

A trammer in a Michigan copper mine having been killed by the rolling of a large rock from a place in a stope where it had been deposited for subsequent loading by him and his crew, his widow brought suit against the mining company. It appears that decedent had been assured by the miners who excavated the rock and passed it down to the level that the rock was safe, and that it would be blasted in a few minutes to facilitate its loading. The accident occurred before blasting.

*Attorney, St. Paul, Minn.

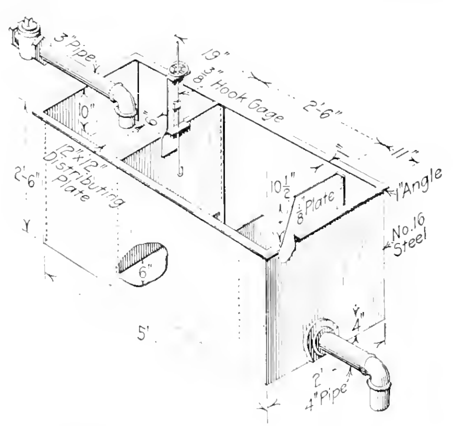
In denying that the mining company was liable for the accident, the Michigan Supreme Court holds that the miners and trammers were fellow-servants in the sense that the company was not liable for negligent failure of the miners to blast immediately. It was further decided that the miners' assurance concerning the safety of the rock could not be deemed to have been given in the capacity of representatives of the company, so as to make it binding upon the company. (Lesh vs. Tamarack Mining Co., 152 Northwestern Reporter, 1021.)

The V-Notch Weir

By John E. Rothwell*

For measuring the continuous flow of water or solution in a concentrating, cyanide or leaching plant, the V-notch weir is probably as simple and accurate a device as can be used. The accompanying isometric drawing shows the general features and dimensions of a measuring box suitable for a flow of 200 gal. per minute, or 1200 tons per day.

The box shown is made of light sheet steel with a 1-in. angle around the top. It can also be built of 1½- or 2-in. plank and made water tight when intended for handling acid solutions or when light sheet steel is not available. The weir partition is made of steel plate for use with water and cyanide solution and is fastened into the box by riveting or bolting, the joint all around being made water-tight. The notch must be carefully and accurately made at an angle of 45° and one side beveled back at an angle of about 60°, the beveled side being placed down stream, or on the overflow side.



CONSTRUCTION OF THE V-NOTCH WEIR

The baffle partition is placed as shown, and has a space of about 6 in. between its bottom edge and the bottom of the box. This, together with the distributing plate, serves to give a quiet surface ahead of the weir to which the measurements can be made.

The hook gage is made of ⅜-in. round iron, steel, copper or bronze as seems necessary, with a hook about 3 in. long and 1½ in. wide, the end of the hook being pointed

*Mining engineer, 850 W. Broadway, Butte, Mont.

about as one points a lead pencil. The extreme point is made spherical, about $\frac{1}{2}$ in. diameter. A thread is cut on the long part for about 12 in., and a handwheel, similar to that used on a 1-in. globe valve, is threaded to screw on the rod. A vernier plate of brass is attached to the rod as shown, and a gage plate, also of brass, about 12 in. long by $1\frac{1}{2}$ in. wide, accurately marked in inches, tenths and twentieths, is made and the whole mounted on a bracket as shown attached to the baffle partition.

The box is now ready to be placed in the circuit of the flow to be measured. It is leveled lengthwise, and a vertical line from the apex of the notch should bisect the base or widest part of the notch. Then with a transit or level and a special rod the point of the hook gage is set absolutely level with the apex of the notch, and the gage adjusted to the zero of the vernier. It is now ready for the water or solution to be turned in.

The flow is measured by turning the handwheel, thus raising the hook, until it is observed to form a small "pimple" on the quiet surface of the water just above its point. The reading of the gage is then made and noted. Reference to the table with this reading or its nearest twentieth gives the cubic feet and U. S. gallons per minute with reasonable accuracy.

Then

$$\frac{GPM}{4} = tons\ per\ hour$$

$$GPM \times 6 = tons\ per\ day\ (24\ hr.)$$

If the tonnage flow for 24 hr. to zinc boxes is required—this flow is usually a fairly constant one—take the reading every hour and note it on a record sheet. Then the sum of the cubic feet represented by the individual readings $\times$ 1.875 = tons per 24 hr. The factor used is based on 32 cu.ft. per ton of solids of specific gravity 1.0032 at 60° F.

Having the assay per ton of the solution in Au and Ag entering the boxes and the value per ton in the overflow, which tonnage will be the same, the value deposited in the boxes can be determined and a close check on the mill operation obtained.

It is also possible, when a plant is so arranged to obtain a check on the dry tonnage handled by determining the specific gravity of the pulp in transit. An accurate knowledge of the quantity flow is invaluable in both the "counter-current agitation" system and the "counter-current dilution and washing" systems. In wet concentration the measuring box is valuable in the control of water flow at different points.

Automatic recording devices attached to the box will give a fair check on the work of the mill, and increase the vigilance of the men operating in the department so controlled. The recorder should, however, be used only to supplement the hook-gage measurement when solutions are measured, as the float-operated or pressure-operated recorder results may be vitiated by the accumulation of a deposit on the float, or a condition analogous to adsorption, in which air or gas bubbles attach themselves to the float changing the displacement and thus the record. The same reasons apply to the pressure diaphragm recorder.

A manufacturer in the East makes a "water-flow recorder," using the V-notch weir in connection with an ingenious recording device that has calculation-saving features, which, for such operators as can stand the investment, is probably the most accurate device on the market. For the small milling company whose treasury will not permit such an expense, but whose mill operator is desirous of a better control of the working of his plant, the box described here in connection with the accompanying table offers a simple, accurate and comparatively inexpensive substitute.

Russian Copper Output in 1914*

The report of the Russian Copper Syndicate, "Medj," for 1914 shows that copper smelteries failed to reach their predicted output. Instead of exceeding that of the previous year by about 15,000,000 lb., the production decreased, as is shown in the accompanying table.

STATISTICS OF RUSSIAN COPPER PRODUCTION

1910	49,773,990 lb.	1913	73,967,471 lb.
1911	56,476,401 lb.	1914	71,088,312 lb.
1912	74,485,216 lb.		

The 4% decrease of 2,879,158 lb. last year is attributed by the report to the war, which caused the shutdown of the Dzansul plant of the Caucasus Copper Co., prevented resumption by the Kwarzchana works of Siemens' Successors and reduced the working forces in general. There was a recession in the first half of the year on the part of the smelteries, excepting Kyshtim and Werk-Issetsk.

The production of the smelteries for 1915 is estimated in the report as follows:

ESTIMATED RUSSIAN COPPER PRODUCTION IN 1915

	Lb.	Inc. or Dec.
Demidov Estate	2,708,250	—36,844
Bogoslov Works	7,222,000	—1,279,629
Werk-Issetsk Works	11,555,200	+5,276,682
Kyshtim	24,554,800	+7,360,120
Spassky Copper Mine	10,833,000	+359,402
Siberian Copper Co.	1,444,400	+544,249
Alexejev	1,444,400	+609,789
Caucasus Ind. & Metal Co.	10,110,000	+1,113,235
Siemens' Successors	1,083,300	—695,945
Caucasus Copper Co.	.....	—6,952,547
Various works	7,222,000	+840,424
	78,177,350	+7,089,334

According to the report, 91.8% of the total Russian copper production was by Medj Syndicate works, against 95.7% in 1913. The total Russian copper consumption amounted in 1914 to 74,831,402 lb., which is 383,271 lb. more than in 1913 and 9,956,916 lb. more than in 1912. It appears that the domestic production of smelteries and electrolytic refineries is not sufficient to meet the home demand.

Aluminum and Bauxite in 1914

The Geological Survey reports that the quantity of aluminum consumed in the United States in 1914 was 79,129,000 lb., against 72,379,000 lb. in 1913 and 65,607,000 lb. in 1912. The value of the exports of aluminum and of manufactures of aluminum amounted to $1,546,510 in 1914, as compared with $966,094 in 1913. The quantity of crude and scrap aluminum imported in 1914 was 16,241,340 lb., against 23,185,575 lb. in 1913. In addition manufactures of aluminum valued at $1,308,036 were imported in 1914, an increase of $247,807 over the previous year.

The production of bauxite in 1914 was 219,348 long tons, an increase of 9077 tons over 1913, and the largest quantity ever reported.

Details of Practical Mining

Cheap Method of Transporting Cordwood and Timbers

By J. D. Hubbard*

The cordwood problem at many mines is more or less a serious one in relation to costs. The majority of mines are situated in mountainous regions where steep grades obtain, making hauling of any kind a serious cost factor.

At the Oriental Consolidated mines in Chosen a great amount of cordwood is consumed annually. The cost of hauling cordwood and timbers in carts and on pack trains on the steeper trails became greater as the more available timber was cut off. Finally an employee of the company suggested the present plan, which was adopted and which resulted in a great saving to the company.

A steel cable was swung and well anchord at both ends, with sufficient height above ground to keep the bundles of wood from striking, and with a grade of at least 25°. Spans of 4000 or 5000 ft. are not too long. Old steel cables, after being used to their limits for hoisting, may be used for this work. They are worn out by friction eventually, but greasing the cable from the upper end lessens the wear on the rope.

The wood is placed in bundles on a frame, a short length of hemp rope slung around it and fastened to the "rider" by a simple timber hitch. The rider is notched at the proper place to receive the hemp rope, and at another place to ride the cable. The bundle of wood is then tripped and gravity does the rest, the bundle taking care of itself upon striking a bumper at the lower end. The wood is spread over the landscape somewhat upon striking, but is easily gathered up. The amount of splintering depends on the kind of bumper used, and experience shows the best plan.

The hemp ropes are used over and over again, being gathered up and returned to the top landing by the coolie carriers employed for the purpose. Mining timbers of average length are transported the same way. The whole device is simple in the extreme and can be readily installed with a small amount of labor. The illustrations exemplify the simplicity of the operation.

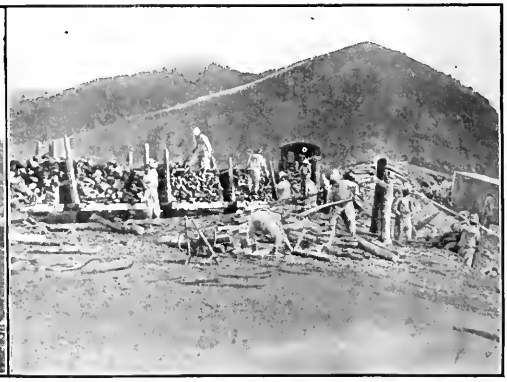
"TRIPPING" LOAD OF CORDWOOD BY CABLE



UNLOADING WOOD AT UPPER END OF CABLE

Application of Roller Bearings to Mine-Car Haulage

By Phillips N. Case*

A few years ago the average mining operator considered a roller-bearing mine car a luxury to be indulged in only by the most fastidious. Today roller bearings in mine cars are acknowledged to be essentials in obtaining maximum efficiency. In metal mines the use of roller-bearing cars is now felt to be imperative; the reduction of haulage expense also constitutes a vital problem in coal mines on account of the long hauls, heavy tonnage and motor haulage now usually encountered in the large operations. In a recent tour of practically every important Western mining district, I did not find a single locality in which roller-bearing mine cars were not in evidence. As the mining profession has now come to realize that the consideration of roller bearings in connection with haulage problems is of paramount importance in the economy of power, oil, labor and maintenance, an outline of the several standard methods of applying roller bearings to mine cars, together with a brief statement of the conditions under which each is especially applicable, may not be amiss.

The methods of installing roller bearings in mine cars may be classified under three heads—(1) wheel hub, (2) inside box and (3) outside box. The wheel-hub applica-

*Sales engineer, Hyatt Roller Bearing Co., Newark, N. J.

tion (Figs. 1, 2 and 3) is at present in most common use, owing in part to the fact that it is a simple, economical construction that does not materially alter the design of the car boxes and trucks in use previous to the adoption of roller-bearing equipment. Moreover, as the bearing is in the hub, the height of the car body is not necessarily increased over that required with the use of a plain bearing. This point is particularly advantageous in cases where the head room is limited. In addition, this construction does not involve incasing the axle, as in the construction shown in Fig. 4. Where the track gage is wide such casing would prove heavy and cumbersome.

Considerations in Designing Applications of the Wheel-Hub Type

Though the wheel-hub application has in its favor the points enumerated, there are several factors that must be carefully considered when designing a wheel-hub installation in order to obtain a high efficiency. The most important of these is the thrust exerted by the flange when the car is rounding a curve. As the wheel hub is not a rigid box, the thrust that the flange receives from the track on the curve exerts a turning moment against the inside end of the bearing. Therefore, in order that the rollers may not be injured by this thrust, it is essential that the bearing project far enough inside of the load line to take care of this severe duty. To accomplish this, it is best to place the bearing in the hub in such a way that the center line of the bearing coincides with the track gage. Moreover, if this rule be followed, the load is centered, resulting in a uniform distribution of the weight, in the case of flexible bearings affording a full line of contact, when the car is traveling on a straight track. It may be readily understood that because of the resilience inherent in the construction of hollow-spiral rollers, this type of roller bearing is superior to any solid-roller bearing in resisting effectually the severe flange thrust. Another point to be considered is the fact that with a bearing in the hub of a wheel, it is usually difficult to exclude dirt, this being particularly true in cars which are side-dumped. This point should therefore be weighed when designing a wheel with such a bearing. Moreover, with the wheel revolving about the bearings, there is a tendency for the oil to leak out unless well packed. The hollow-spiral rollers of the Hyatt bearings constitute oil reservoirs and as the spirals are alternately right and left hand, a thorough circulation of oil is assured.

Three Wheel-Hub Applications

There are many methods by which bearings may be properly installed in the wheel hub—more, in fact, than I shall attempt to describe here. However, Figs. 1, 2 and 3 illustrate three efficient methods of applying roller bearings, either solid or spiral, in the hub. The cotter-pin application (Fig. 1) presents small opportunity for friction at the outer end of the wheel hub, while the large plate washer at the inside end affords a broad surface for receiving thrusts and in this application is well lubricated by oil from the bearings. At the outer end of the hub, a steel compression ring fits around a leather washer on the axle, thus effectually eliminating leakage of oil at this point.

The application in which the wheel is held on the axle by means of a collar (Fig. 2) is an example of a strong wheel embodying simple construction, with a solid hub at the outer end, affording no opportunity for dirt to enter or oil to leak at this point. In this case the thrust is taken by the collar.

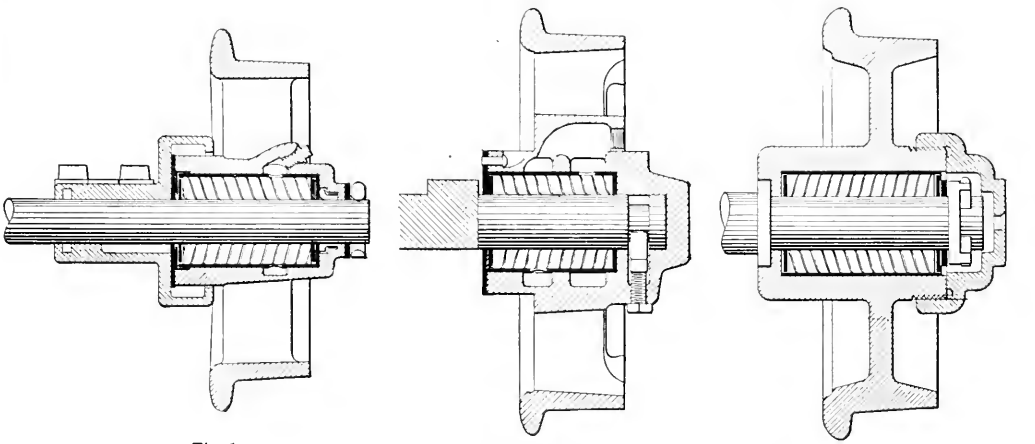


Fig. 1 Fig. 2 Fig. 3

THREE WHEEL-HUB APPLICATIONS OF ROLLER BEARINGS TO MINE CARS

Fig. 3 illustrates a well-designed application of the cap type. Where a cap is employed at the outer end of the hub, it is essential that it be held securely. In this design this is accomplished by threading the cap on the hub, and yet the bearing is readily accessible by simply unscrewing the cap. The end thrust is taken by the collar on the axle.

Selection Depends Upon Operating Conditions

The wheels above described are representative examples of applications in common use, a selection depending upon the conditions at the particular mine in which they are to be used and also upon the ideas of the mine operator. Whatever methods of applying roller bearings in the wheel hub may be favored by any particular mining man, in my opinion it is an advantage to employ a round axle which

is free to turn and thus slips around slightly from time to time, evenly distributing around the axle the load transmitted by the rollers.

Inside-Box Applications

Considering the application of the inside box to the roller bearing, this may be subdivided into two classes—(1) the Anaconda type of wheel and axle shown in Fig. 4, and (2) the angle-iron type shown in Fig. 5, in which the boxes at opposite ends of the axles are braced by angle irons. In the latter type it will be noted that a beveled, self-aligning box is used. This has a decided advantage on uneven tracks, as an opportunity is afforded the box to maintain its alignment. However, except in the case of a wide-gage track, the Anaconda design is undoubtedly preferable, for here the casing affords a rigid box and the whole design is therefore more conducive to stability. In connection with the Anaconda type, the self-aligning box would undoubtedly be an improvement. The thrust in the Anaconda wheel and axle is taken on the heavy flange washers which are threaded over each end of the box protecting the end of the bearings. It should be observed that one wheel is loose on the axle, being held by a cotter pin, while the other is pressed on the axle. The purpose of this is to afford a differential in rounding curves. Owing to the fact that the inside-box applications necessitate slightly greater head room over that required in the case of a plain bearing, there are some instances where they are inapplicable. However, the inside-box type represents in many respects a more efficient application than any wheel-hub type and has become popular in the metal mines in such districts as Montana, Arizona, Idaho, Colorado and Lake Superior.

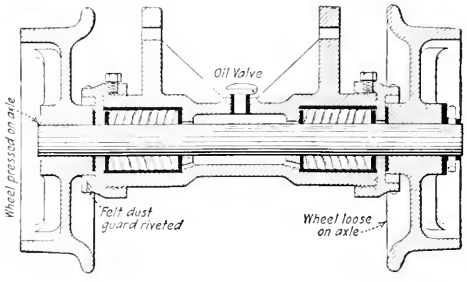

Fig. 4

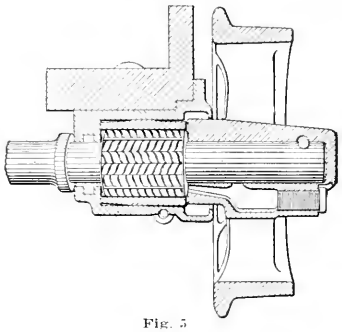

Fig. 5

INSIDE-BOX TYPES OF ROLLER-BEARING WHEELS AND AXLES FOR MINE CARS

Outside-Box Type Most Efficient

In considering the outside-box application (Fig. 6), it may be stated at the outset that where applicable this is the most efficient installation. In the design illustrated, the thrust is taken at the inside end of the box (*A*, Fig. 6). But this point could be easily modified so that the thrust would be taken between the end of the axle and the cap, in which case the surfaces would be well lubricated by oil flowing from the bearings. In regard to the felt packing at the inner end of the box, it may be well to call attention to the method of compressing a square felt packing into a tapered recess.

It will be observed that in the case of the outside-box applications, the bottom of the car body must necessarily be raised above the wheel and the axle must project beyond the wheel, so that this type of equipment is prohibited in narrow or low haulageways. However, many mines employ spacious main-haulage tunnels, through which trains may be hauled by motors at considerable speed, thus affording ideal opportunity for the use of this installation. As an illustration of the efficiency which may be obtained under these conditions, a mine in Idaho may be cited. The entrance is by a tunnel about two miles in length, through which long trains are hauled at a high rate of speed by electric motors. Upon a recent visit to this mine I was informed that the first of these tunnel cars—equipped with Hyatt roller bearings in outside boxes—covered 3000 miles in four months, without any attention and without any ill effects. At present all the cars in this tunnel are equipped with these bearings. The capacity of the cars ranges from 3 to 4 tons of ore, and the service is severe; nevertheless, excellent results are being obtained. Such experiences prove that it is possible in the case of an outside-box application, and to a lesser degree in the case of an inside box, to use with perfect safety bearings of shorter length than would be required were they installed in the wheel hub. With large cars and heavy loads this is a decided advantage.

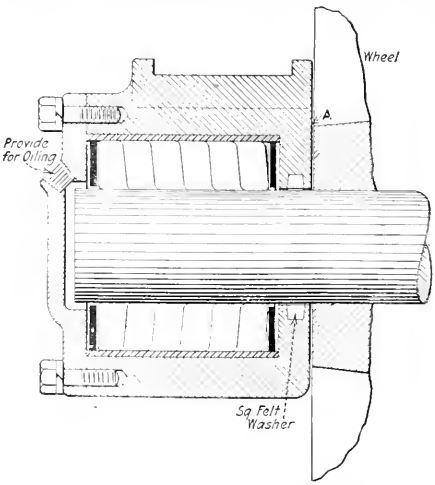

FIG. 6. OUTSIDE-BOX APPLICATION

Details of Milling and Smelting

Marcy Ball Mill Described

Mill operators have been patiently awaiting some technical description of the Marcy ball mill, which has been tried with apparent success and is being installed in some of the larger plants at the present time. No description by the inventor has been forthcoming, because of pending patent applications, but U. S. pat. 1,137,878, granted to F. E. Marcy on May 4, 1915, gives a general description of the mill in question.

The Marcy ball mill is of the drum-type, equipped with the usual spiral feeder and loaded with pebbles or balls as may be required. The drum is divided into two parts—the crushing compartment, equipped with lifters to insure the elevation and dropping of the balls to secure maximum crushing efficiency, and a small compartment at the end of the mill, separated from the crushing space by means of a manganese-steel plate and

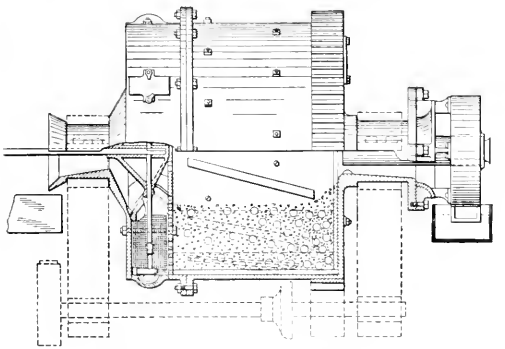

DIAGRAM OF THE MARCY BALL MILL

having perforations about $\frac{1}{8}$-in. wide. In this end compartment there are radial screens and lifters, the lifter forming the bottom of a box the top of which is formed by the screen itself. These are the finishing screens, and material which will pass through them is considered as being of finished size. The material passing through the screens is diverted by arrangement of the compartment so that it will be discharged through the central orifice; while the oversize—material which remains on the screen—is diverted back into the mill through a proper opening. The screens and lifters form a box, as has been stated, and are placed so that they may be removed from the outside of the mill for rearrangement or cleaning. In order to give the screens maximum efficiency and to increase their life, an arrangement of pipe is made so that water or solution under head can be thrown against them while the screen is passing through the upper half of the circle formed by a cross-section of the mill.

The action of the lifters, in addition to forming the bottom of the box and assisting in the screening operation, is to maintain a low pulp level in the mill. It is clear that by constantly removing the solution and pulp from the bottom of the crushing drum, a removal of the material already sufficiently finely ground is accomplished rapidly and no energy is lost in doing work where it is not required. The coarser material is left in a comparatively dry state upon the balls or pebbles, and the crushing and grinding action of the mill can have maximum effect upon it. The accompanying drawing shows a longtitudinal view and partial cross-section of the mill, giving a clear idea of its construction and operation.

*

Improvements for Ropp Roasters

By Edgar Hall*

The Ropp roaster although extravagant in fuel has many good points. It can be built cheaply, costs little for repairs and requires no great amount of brains to keep it at work. The use of producer gas reduces the fuel bill, and doubtless it would not be difficult to devise means of conserving heat and lessening the excessive influx of cold air, which would effect further economies. Possibly they have already been introduced, although as yet undescribed in the technical journals. About 10 years ago a Ropp roaster, supplied to the Mount Morgan Gold Mining Co., was purchased by the Silver Spur Mining Co., and has been in use ever since, roasting a complex zinc-lead-copper ore in preparation for matte smelting.

The machine as supplied by the patentees was fed by two Challenge ore feeders—one on each side of the slot—and the four rake carriages had flangeless wheels which were prevented from running off the semi-circular turns in the rails at each end of the furnace by small bogie under-carriages of an elaborate character. Both feeders and rakes had numerous wearing parts requiring constant attention and lubrication, particularly the bogies on which the consumption of oil, owing to the heat in passing through the furnace, was enormous for the work done. It was soon evident that improvement was possible in these parts of the machine.

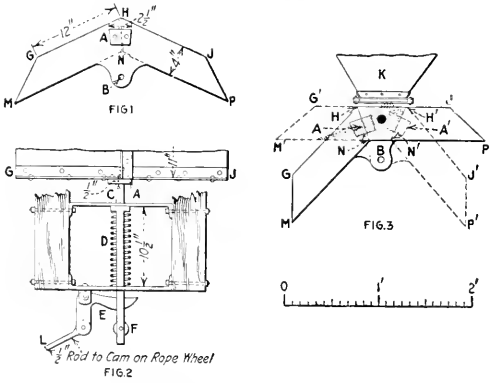
The Challenge feeders were abandoned for the single, overbalanced, tripping type of feeder shown in the accompanying drawings. This is an advantage in every respect. It requires less power, less attention, feeds more evenly on each side of the slot and has cost nothing for repairs and practically nothing for lubrication, only an occasional drop of dirty oil from the engine being required. In first cost the comparison is as great, since only one storage hopper is needed and the feeder itself can be made in a day by a skillful blacksmith, using short ends of plate and rod.

Feeders of this type were in use long ago, in tin-dressing sheds for supplying water to slime tables, but

*Silver Spur Mining Co., Silverspur, Queensland, Australia.

I have not heard of any being used for dry material. There is no reason why they should not be more generally used. For finely crushed ore they work well and probably would be satisfactory on any fairly uniform material of moderate size. At Silverspur the ore was crushed to pass $\frac{5}{16}$-in. square holes, but at times the feed was larger. The feeder consists of two short chutes (*GHNM* and *HJPN*, Fig. 1) of steel plate set together at an angle and placed immediately over the slot and under the mouth of a storage hopper, to the timber frame of which it is fastened. It is free to move on the axle *B*, but is kept in position by the pin *C*, Fig. 2, acting against the shoulder of the block *A*. Figs. 1 and 2, riveted to the outside of the chutes. The pin *C* is held in position by the spring *D* and is moved by the cam *E* acting on a small disk *F*, revolving loosely in a slot in *C*. The cam *E* is attached by a rod *L* to a shoe (not shown) which is struck by a cam on the rope sheave which drives the rakes.

The revolution of the sheave brings the cam over the shoe connected with rod *L*, which pushes the pin *C* out from one side of the block *A*, releasing the chute *GHNM*, which then tips over and is again fixed by the return of pin *C*—through the action of the spring *D* as soon as the



FEEDER FOR ROPP ROASTER

cam on the rope wheel has passed the shoe—to the other side of the block *A*. The next movement of *E* reverses the action. The mouth of the hopper *K*, Fig. 3, is provided with a sliding shutter worked by a screw by which the feed can be adjusted to fill the chute to the amount required for easy working of the feeder.

It is obvious that one side or the other of the chute is always level and parallel with the mouth of the hopper, and that when the slide is open the crushed ore will fall through and pile up on the chute until the opening is blocked by the natural slope of the small pile so formed. Fig. 3 illustrates in diagrammatic form the working of the appliance. The mouth of hopper *K* being open and the chute shown in dotted lines in the position *G'H'N'M'*, a small pile of ore *O* forms and blocks the openings. Presently the revolution of the rakes causes cam *E* to move pin *C*, when the weight of ore on the chute *G'H'N'M'* overbalances the chute and it falls over and discharges its load on the floor of the furnace on the left side of the slot. The chute now has the position *GHJ* and is filled with ore on the side *HJPN* in like manner, and at the next movement of cam *E* falls over and discharges an equal quantity of ore on the floor of the furnace on the right side of the slot. By increasing the number of cams on the rope wheel the quantity fed can be multiplied to any extent, and will remain equally divided between the two sides of the furnace. The feeder of the size shown was equal to 20 tons per day with one cam only on the rope wheel.

I next tackled the rakes which, in spite of the elaborate bogies, would not keep on the rails. The ubiquitous greased flat-sheet of the miners suggested itself. It was easy to try it and I did; the experiment succeeded. The result was that the semicircle of rails at each end of the furnace was taken up and circular tracks of smooth-faced cast iron put in their places. The bogies were removed and the rake carriages placed on fixed axles carrying ordinary mine-truck flanged wheels. The flanged wheels run in the usual manner over the straight lines of rails under the slot and on the return line outside the furnace, but in turning at the ends of the furnace they run on the rims of the flanges over the cast-iron plate tracks, the greased surface of which allows the revolving wheels to perform easily the small slithering movement needed to enable them to follow the rope around the semicircle. Wooden guides fitted at the side of the entrance of the straight lines of rails lead the wheels safely off the plate track to the rails.

The improvement is immense. By dispensing with the bogies the weight of the four rakes is lessened by 1064 lb., nearly half a ton less to be hauled constantly around and through the furnace, and friction is much reduced. There is a great saving of time as the rakes seldom leave the rails and there is no stoppage for oiling the many moving parts of the bogies. The cost for lubricant falls to almost nothing, as waste oil from other machinery can be used for the tracks and the constant renewal bill for bogie parts and rollers disappears.

These alterations have stood the test of years, and are described on the chance that the methods may be applicable to other machines involving similar movements.

Lead Acetate vs. Litharge

By C. R. Morris*

During a series of experiments carried out at the Mexican mill, Virginia City, Nev., it was found that there was not much difference in the mill between using one or two pounds of lead acetate. Our acetate supply

EFFECT OF LITHARGE AND LEAD ACETATE ON EXTRACTION

	Aug.	Sept.	Oct.	Nov.	Dec.
Heads, oz. Ag	629	714	728	661	878
Tails, oz. Ag	108	112	135	65	79
Extraction, per cent	83	84	82	90	91

Litharge, lb	..	..	..	¾	¾
Cost per ton, c	.14	.22	..	.09	.09

failed in October and on this account we were compelled to use litharge, putting it into the tube mill three times a day. The extraction appeared to be as good as with the use of lead acetate. In November we received a supply of lead acetate and used both salts, ¾ lb. of litharge in the tube mill and ¼ lb. of lead acetate in the agitators. This combination of salts gave a better extraction. Results are shown in the accompanying table.

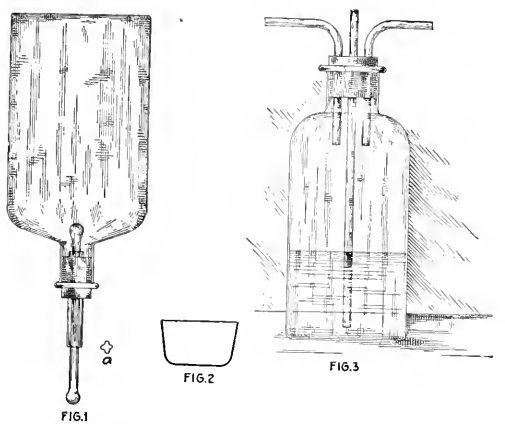
The Assayer and Chemist

A Rapid Method for Washing Gold Beads

By E. J. Hall*

The suggestion by W. S. Black, in the *Journal* of Dec. 26, 1914, for an improvement in the time-honored method of parting and washing gold-silver beads appeared so attractive that I immediately set up his apparatus, except for the interposition of a bottle containing a solution of sodium carbonate between the suction bottle and metal piping to the pump—the fumes from hot acid were strong—and found that the method met all his claims.

I believe, however, that the proposals mentioned below are improvements. As stated by Mr. Black, there is



APPARATUS FOR WASHING GOLD BUTTONS

little trouble from the loss of fine gold, and the saving is closer than by decantation. If the fine gold starts to move across the bottom of the cup, the velocity of the liquid may be retarded or stopped by pinching the rubber tube. Here there may be some trouble with the apparatus as described, with a good head of water, since the Richards pump is capable of giving a vacuum of nearly 30 in. of mercury, and when the pressure on the tubing is released, everything in the cup is likely to disappear if the suction tube is not instantly removed. To overcome this difficulty a vacuum regulator is inserted in the line beyond the suction bottle. This is the common mercury bottle illustrated by Fig. 3, and is frequently used in suction filtration and where such apparatus as pipettes and burettes are filled by suction. The suction is regulated by the height of mercury above the bottom of the relief tube, and will be found satisfactory for this work at one inch.

*Department of Metallurgy, Columbia University, New York City.

The common practice in parting is to add strong acid or wash water as soon as the liquid has been decanted and to put the cups back on the hot plate, or else after decanting to place the cups on a table until this operation is completed. Then the succeeding liquid is added and the cups replaced on the stove. For dispensing the liquid either a beaker or the method suggested by Mr. Black is used, though the latter cannot be successfully employed for strong nitric acid. This procedure is at variance with Mr. Black's treament—where the cups are allowed to dry and bake between applications—and, on the average, will give cleaner gold.

The addition of acid and water from a beaker to the cups without taking them from the stove, immediately following removal of the solution, proved unsatisfactory and therefore the liquid-dispensing bottle illustrated in Fig. 1 was constructed. The bottom of a narrow-mouth glass bottle was cut off. Next a piece of 5-mm. glass tubing was cut true on one end and the edges slightly rounded in a blow-pipe flame. The other end was softened and pressed in with a pointed instrument at four places (*a*, Fig. 1), leaving just sufficient clearance for a 3-mm. glass rod to pass freely. The top of a 3-mm. glass rod was held vertically and rotated in the blow-pipe flame until a ball 6 to 7 mm. in diameter had formed. The rod was inverted and ball heated till it assumed a pear shape and was then allowed to cool. This was inserted into a tube, a paste of 60-mesh emery applied at the point of contact between bulb and tube and ground to a good seat, then polished with a paste of 150-mesh emery, obtaining a perfectly tight valve. Almost any abrasive may be used. A ball formed on the other end of the rod prevents it slipping from the tube. To cement the valve in place it is inserted in the small end of a cork about ⅜ in. and introduced into the neck of the bottle from the inside; the neck is then filled from the mouth with sulphur-sand cement and when set the cork is removed. The dispensing bottle is then set in a wide-mouth bottle, its shoulders resting on the top, and may be filled with any desired liquid.

The details of parting with the apparatus are as follows: After the action of the weak acid on the beads has ceased, the cups are filled with distilled water—to dilute the silver nitrate—by lowering the glass rod of the dispensing bottle into the cup and pressing on the bottom, thereby opening the valve. When a cup is full, the bottle is raised and the valve closed. When the cups are full the water may be changed and strong parting acid used or another dispensing bottle procured.

If 4-cm. Royal Meissen capsules (Fig. 2) are used instead of the customary crucibles, a slight pressure with the suction tube at the point where the bottom curves into the side of the cup will cause the cup to tilt sufficiently to permit complete removal of the liquid. Another advantage of these capsules is their self-righting character, which makes them more convenient to handle. The suction tube is then moved to the next cup, and while

the solution is being removed, strong parting acid is added to the preceding cup from the dispensing bottle, thus preventing premature drying of the gold and enabling the carrying out of two operations at once. After all the cups have been treated in this manner the acid is diluted and the operation repeated, using water instead of acid. If the beads are sufficiently high in silver to part completely or nearly so in the weak acid, one water wash will usually be found sufficient, particularly if the silver is not over 50 mg. We found that the working time of parting had been reduced approximately one-half by the above procedure and its unpleasantness by 90%. Therefore, Mr. Black is to be commended for his suggestion on a process which is so old that no one imagined it could be improved.

*

Assaying Gold-Bearing Cyanide Solutions*

The method here described has been used at the plant of the St. John del Rey Company, at Morro Velho, Brazil, and has proved satisfactory. It is operated by native assistants without any difficulty and yields accurate results which have been carefully checked against the evaporation methods. The method is based on the precipitation of gold by means of zinc shavings, or rather by a zinc-lead couple, from the boiling solution, in the presence of considerable quantities of silver and lead salt. Sufficient silver is introduced to yield with the gold a suitable parting alloy. The presence of lead salts causes the formation of a zinc-lead couple which facilitates the complete liberation of the metallic gold from the solution and yields a bulky precipitate of lead and precious metals which settles easily and thus insures the ready and complete carrying down of the precipitated gold.

The stock solutions consist of a silver solution containing one grain of silver for each 10 c.c. Thirty-six grams of silver-nitrate crystals are dissolved in water, sodium cyanide added in small quantities until the precipitate which first forms is redissolved, and the solution then diluted to $2\frac{1}{2}$ liters. The sodium cyanide solution is a 10% mixture, 250 to 260 grams of sodium cyanide being dissolved in water and diluted to $2\frac{1}{2}$ liters. Sodium-plumbite solution contains 65 grams of lead acetate dissolved in water with sodium-hydrate solution added until the precipitate first formed just redissolves, and the solution diluted to $2\frac{1}{2}$ liters. This solution is preferred to the simple acetate solution usually employed, since it insures the alkalinity of the liquid and the consequent absence of free hydrocyanic acid which might otherwise tend to carry back some gold into the solution.

The procedure is to take one pound, or 7000 grains, or 453.6 c.c. of the solution for assay; this volume is poured into a flask of $1\frac{1}{4}$ liters' capacity and the silver solution added. For rich solutions, 15 c.c. of the silver solution is used, and for the poorer solutions and for wash waters only 5 c.c. Next, 10 c.c. of the sodium cyanide solution is added, then 5 c.c. of the plumbite solution, and the mixture shaken.

Then, 20 grams of zinc shavings is placed in the solution and the contents of the flask gently boiled for half an hour and then filtered at once through a 9-in. filter paper, the clear filtrate being rejected. To the flask containing the solution and shavings, a little water is added, about 20 c.c., only just so much being required as will prevent the cracking of the flask by the drying and heat produced on the subsequent addition of the acid, then 30 c.c. of commercial hydrochloric acid. After the complete solution of the zinc, the contents of the flask are poured on the filter, flask and filter being subsequently well washed with water.

The wet filter is transferred to an assay crucible, dried slowly in the furnace and carbonized at moderate heat. The crucible is withdrawn from the fire and a flux is then added, consisting of this mixture:

FLUX FOR MELTING THE PRECIPITATE

Red lead	$12\frac{1}{2}$ grams	Flour	2 grams
Borax	$22\frac{1}{2}$ grams	Powdered glass	2 grams
Sodium carbonate	$12\frac{1}{2}$ grams	Potassium nitrate	2 grams
Sodium chloride	2 grams		

The crucible is then returned to the furnace and the charge run down in the usual manner, from 20 to 30 minutes being required to complete the fusion, after which the contents of the crucible are poured into a conical mold, the metallic button detached when the mass has cooled, and cupelled in a small magnesite cupel, the resulting beads being parted directly in the usual manner, usual manner.

*

Electrolytic Method for Copper in Nitric-Acid Solution

The following note on copper determination by electrolysis is by H. Clonkey of the Forest Products Laboratory, Madison, Wis. (*Journ. Ind. Eng. Chem.*, March, 1914):

In the electrolytic determination of copper from nitric-acid solutions the deposit is bright and adherent, if the correct acidity-concentration conditions have been maintained. When the acid concentration is too low the film has a dull look and may not be adherent. If the acid concentration is too high a long time will be required completely to deposit the metal, although the deposit will be bright.

In those cases where it is inconvenient to limit the amount of free acid in bringing the copper into solution in preparing for the electrolysis, and where the results of the analysis are needed in the shortest possible time for control work, this excess acidity can be easily controlled by a little powdered sodium acetate.

In preparing the solution for electrolysis all the nitric acid can be used that is necessary to bring quickly into solution the copper, copper salts, or compounds containing copper. Then, after the electrodes have been mounted, the current switched on and current density adjusted, if the copper does not promptly start to plate out, a little sodium acetate dusted into the solution will fix the excess of nitric acid which is dissolving the copper film as fast as formed.

The change in the character and speed of deposition will be almost instantaneous, and the deposit will be bright, adherent, and formed in the minimum of time. The treatment of the solution with an excess of sodium acetate at the end of a deposition in order to change the free nitric acid to sodium nitrate, and thus enable the electrodes to be removed without previous washing, has been recommended often, and the action is the same in both cases, differing only in degree.

*Excerpts from an article by J. M. Levy and Harold Jones, in "Bulletin No. 128" of the Institution of Mining and Metallurgy, May 13, 1915.

Broken Hill Milling Practice*

SYNOPSIS—The Broken Hill lode is not of great extent, but the large variety of ore produced makes necessary a diversity of milling practices. Breaking, crushing, grinding and regrinding are about in conformity to usual practice. Screen sizing is preferred to hydraulic classification. Both jigs and concentrating tables are used.

Although the Broken Hill lode in New South Wales, Australia, is only two miles in extent, the characteristics of the ore in the various mines render the adoption of a standard method of treatment impracticable. The ore consists mainly of lead and zinc sulphides, quartz, rhodonite and garnet sandstone, and it is the varying quantities of the gangue constituents, as well as the variation in degree of crystallization of the mineral contents, which enforce the need of different methods.

Power and Crushing Systems

Some of the mills are driven by steam engines directly connected with the main mill shaft by rope drive. Of late years, however, the general tendency has been toward the installation of three-phase induction motors, each important machine or group of machines being driven by a separate motor. The current for driving the motors in the mill is usually generated at a central power plant. The practice is to run each mill in sections, usually of about 1500 tons per week capacity, so arranged that a breakdown in any section only temporarily stops that section and not the whole mill.

Magnets are used at the head of the crushing system to remove lumps of iron, and grizzlies are in general use. The gyratory crusher is preferred to the jaw type. The present tendency is to crush finer than formerly with the gyratory breaker so as to increase the roll capacity, the size of the product leaving the gyratories being about 1½ in. With an ore such as that in the Junction North mine, containing a high percentage of extremely hard rhodonite, this is particularly desirable. In such a case it is usually necessary to have two gyratory crushers in series, a grizzly at the head of each machine. With a moderately hard ore, a single gyratory will crush 45 tons per hr. from 8 in. down to 1½ in. The average horsepower per machine is about 30, but there is often a peak load as high as 50 hp. A small jaw breaker following the gyratory for intermediate reduction, which used to be a feature of Broken Hill practice, has been dispensed with almost entirely.

Extensive Use of Rolls

The roller system is usually employed for feeding the ore from the bins to shaking screens at the head of the rolls. A flange roller, 10 in. in diameter and 15 in. long, traveling from 4 to 8 r.p.m.—the rate being regulated by a ratchet and pawl—is used. The quantity of feed is regulated by a door worked by a rack-and-pinion over the roller, and in some cases the door is tapped automatically by a rod from the shaking-screen gear so as to keep the ore in motion. Shaking screens at the head of the rolls are now universally used. The importance of efficient screening ahead of the rolls is often overlooked, but bad screening at this point causes undue sliming and is often the cause of low recovery, especially in the case of a hard ore. Shaking screens, suspended from above by hickory springs or eye-bars, are rigidly connected to the eccentrics which drive them.

In the South mill the feed is first treated on a narrow shaking screen and the reground oversize is afterwards separately treated in trommels. In the British mill a corrugated screen is used to keep the ore well agitated in passing over the screen. The average number of bumps given to the shaking screens is 250 per min. The screens are usually lined with steel-slotted material having a 3-mm. aperture, although in the softer types of ores it is screened to 4 mm. for jigging purpose.

Cornish slow-speed rolls, 36 in. by 18 ft., are almost always used on this field. Their speed is 15 to 25 r.p.m. The shells are made of toughened chrome steel and have double-cone centers bolted together, so that when worn they are easily removed. In some cases the rolls are both gear driven. In other cases one of the rolls is driven by friction. The general practice is to have one roll plain and the other flanged, the plain roll working inside the flanged one. Strong rubber or iron springs are used in all cases. Running the rolls fairly wide open, with a large oversize return, is the usual practice. No lateral movement is given, as the shaking screen at their head provides for even wear.

Series Crushing to Reduce Sliming

Series crushing in rolls, theoreticaly supposed to reduce sliming, has been proven by practical tests to be uneconomical. One large Broken Hill mill which for years has been working two sets in series has now gone back to a single set, the feed being crushed finer in the primary reduction of the ore. Experiments with high-speed rolls have demonstrated their inferiority. The average capacity of a set of rolls is 1500 tons per week, crushing from 1½-in. size through a 3-mm. slotted screen; the average horsepower is 30.

From the roll screens the ore goes into the jigging system. It has been found essential to remove fine sand and slime from the jig feed, otherwise it is a matter of difficulty to prevent them passing through the lead hutches and spoiling the final lead product of the jig. Here the practice is divided. Some of the mills use hydraulic classifiers at the head of the jig, a double-cone classifier being preferred. Others use King screens to classify the jig feed, the product screened out being usually 5 to 10% plus 40 mesh. In some isolated cases where screening or classification at the head of the jig is imperfect the jig lead is classified in a hydraulic classifier, but this system is not to be commended.

Characteristics of Jig Practice

Jigging practice has been greatly modified in the last few years. May jigs have now completely supplanted the Hancock machines formerly in use. Jigging has been developed along two entirely different lines, because of the difference in the nature of the ore treated. In the first practice, which is used on most of the mills and is especially adapted for fine-grained ores, the jig

*Excerpts from an article in "Mining and Engineering Review," Melbourne, May 5, 1915.

is used for recovering coarse lead, no attempt being made to produce on the same primary jig a worthless tailing. The whole of the product, except of course the lead, is recrushed for after-treatment in the tabling system. In some cases a middling product is made and returned to the jig. It has been found that by working the jig on these lines five hutches are not required, and only three, or at the most four, are used. In the second practice two sets of jigs are used, the five hutches in each set being employed. On the primary jig, as in the first system, no rejects are made, the tailings produced being reground and treated on tables. Thus the first jig makes the following products: Nos. 1 and 2 hutches, lead; No. 3 hutch, middlings, which are returned; No. 4 hutch, middlings, which are crushed in positive pans and sent to No. 2 jig; No. 5 hutch, tailings, which are recrushed in tube mills. The object of the second, a fine jig, is to make quartz tailings, which are discarded. In the case of a poorer ore this system may be modified, No. 4 hutch going to the tube mills and No. 5 hutch to the positive pans and then after classification to No. 2 jig. This enables a large rejection of quartz tailings to be made.

The advantages of the second practice are the recovery of the maximum amount of lead before undue sliming has taken place and the saving in crushing costs by the rejection of comparatively coarse quartz tailings. The rhodonite being of high specific gravity must be crushed finer to make a saving of further lead values, and also to make a product suitable for flotation treatment of the zinc which cannot be separated from it by mechanical means. It will therefore be realized that this method is not applicable to ores containing a high percentage of rhodonite. The use of the system mentioned has resulted in large capacity increase per jig, and 2000 tons per week of 144 hours is not uncommon. The speed of the May jig is usually 180 strokes per minute, the length of stroke being variable.

Types of Regrinding Machines

Tube mills and grinding pans are used for regrinding. The normal size of the tube mills used at Broken Hill is 10x5 ft., traveling 28 r.p.m. and using 28 to 30 hp. Both trunnion- and roller-type mills are in use. Cast-iron liners are employed, the general size being 20x13x1¼ in. In some cases longtitudinal bars are used to lift the pebbles, while in others the projection forms part of the liner itself and serves the same purpose. Pebbles in the tube mill are usually kept 2 in. below the center at the feed end and 4 in. below the center at the discharge end, the load of flint weighing approximately 4 tons. A coarse screen is used on the discharge end to prevent small pebbles from going out with the crushed product. Moisture in the tube-mill feed varies from 50 to 60%, being higher than in the case of Rand tube mills, which crush finer. Scoop feeds are used satisfactorily. Pebbles are fed in by hand through the manhole door once a day. This method is satisfactory, as pebble consumption is low, 1½ to 2 lb. per ton of ore crushed. Iron consumption is ⅛ to ¼ lb. per ton.

As a rule the ore is ground from jig size to a size suitable for table operation—that is, 5 to 15% plus 40 mesh—in a single tube mill. On some plants tube mills are worked in series with 5-ft. pans. The tonnage treated under these conditions varies from 5 to 8 per hour.

Grinding pans 8 ft. in diameter are used in some mills. They are of two types: Positive pans, in which the feed enters at the center of the pan and passes straight through between shoes and dies and out of the pan, no classification being attempted by raising the overflow of the pan above the level of the shoes and dies; and ordinary pans, in which the feed is not necessarily in the center and where the grade of crushing is regulated by the height of the pan overflow. The stage-grinding system is in use, and it has been found to be much more efficient than a single-step system. The jig-reject product is run, after a classification, into two 8-ft. positive pans, and the classified product from these pans is further crushed in an 8-ft. ordinary pan.

The Forwood-Down Grinding Pan

The pans of the Forwood-Down type have a speed of 32 r.p.m. In the stage-grinding system they crush 2 to 2½ tons per hr. from through 3 mm. to 10% plus 40 mesh. Shoes and dies used are cast iron. As to the 5-ft. grinding pans, both positive and ordinary types are in use. They are used both singly and in series to crush the feed from jigs to the size required for tables. In each case the product is classified on screens before it passes to the pans. The capacity of the Forwood-Down pans is 1½ tons per hr.; speed, 50 r.p.m.; horsepower, 8. Shoes and dies of cast iron last from 6 to 8 weeks, although manganese steel lasts longer. The cost per ton is practically the same in each case. With cast-iron liners 2½ to 3 lb. of metal per ton is usually worn off.

Tube mills are considered preferable to pans. The crushing may be better regulated, as it depends on the load of flint or pebbles and the proportion of water running to the mills, and not, as in the case of pans, on the state of wear of shoes and dies. Costs, while high with tube mills, are much lower than with grinding pans.

The increased capacity of grinding pans while crushing in series leads one to believe that the most efficient crushing system is stage-crushing with tube mills. Two short-tube mills with classified feed supplying a classifier, the underflow of which delivers into a 10x5-ft. tube mill, should give a high capacity and reduced wear with low power consumption.

Necessity for Efficient Classification

A fact that is often lost sight of is the extreme importance of efficient classification at the head of fine-crushing machinery, for tests with grinding pans have proved that it greatly increases the tonnage treated per machine, and also lessens the amount of slime produced. Screening seems preferable to hydraulic classification, as fine lead will pass through the discharge of a classifier and be crushed to slime, whereas this fine lead will be more readily recovered by efficient screening.

The pulp from the fine-grinding section is thickened if necessary and directed to tables without classification, the slime overflow at the top end of each table being separately treated on special machines. The whole feed is split up either by automatic distribution or cut-off gates so as to give an even feed to each table. The tables are all set at a constant slope, having practically a fixed point of cut-off of the lead. These modifications have resulted in the cutting down of labor costs and an increased efficiency of working.

Both riffle and grooved tables are used, and there is still a great difference of opinion as to their relative

merits. Instead of riffles being cut off diagonally across the table, some of them are extended at the far corner of the tables to its full length, the remainder being cut off in the form of a curve. Middlings from the first set of tables are treated on separate ones, and the middlings formed by the latter tables are returned to their own feed. The usual proportion is three primary tables and one table to treat the middlings. The section of a mill crushing 1500 tons per week usually has 12 primary and 4 middling tables. It has been proved that recovery on the table system is proportionate to the area of concentrating surface.

For the settlement of slimes Dorr thickeners and cone settlers are used. The efficiency and regularity in the working of the Dorr thickeners show such a marked improvement over other slime-settling machines on Broken Hill ores that it is doubtful if in future designs of mills any other machine will be thought worthy of consideration.

The enhanced value of the slime product of late years, owing to selective flotation, has turned the attention of some of the managers to the importance of classifying the slimes from all zinc and tailings products. As the slimes are in all cases higher in lead than the coarser product, the thorough removal of slimes results also in a higher grade of zinc being produced from the coarser products. Tailings are either separated in Caldecott diaphragm cones and thickened pulp run out on the dump on a conveyor belt, or the tailings are run into round vats with filter bottoms and bottom-discharge doors which feed a conveyor running under each vat.

The concentrate from each set of machines is, in the most uptodate methods, run to a system of small draining conveyor belts. These all deliver to a main elevator or conveyor, the drained product being discharged into circular or V-shaped concentrate bins with bottoms of coco matting. These bins are elevated along the railway lines, so that on opening the bottom-discharge doors the concentrate may be rapidly loaded in the cars. Future development in lead recovery lies in selective flotation rather than in improved milling methods.

Gypsum Production in 1914

According to the Geological Survey the production of gypsum in the United States in 1914 decreased in tonnage but increased in value. The quantity of crude gypsum mined in 1914 was 2,476,465 short tons compared with 2,599,508 tons in 1913. The gypsum sold without calcining and used principally as land plaster and as an ingredient in portland cement and paint amounted to 113,687 short tons, valued at $646,799. The material marketed as calcined plaster was 1,656,066 short tons, valued at $6,249,190. The total value of all gypsum marketed in 1914 was $6,895,989.

Gypsum was produced in 18 states and in Alaska in 1914, the same states reporting output in that year as in 1913. The relative rank of the three leading states has remained unchanged for the last four years, New York ranking first, Iowa second, and Michigan third in the output of crude gypsum.

There were 78 gypsum mines, including quarries and pits, reported active in the United States in 1914, one of which is in Alaska. These mines supplied 68 domestic mills, of which 61 were calcining plants and 7 produced ground gypsum only. Four new mills were reported in operation last year, three in California and one in New York. One mill was reported under construction in Nevada.

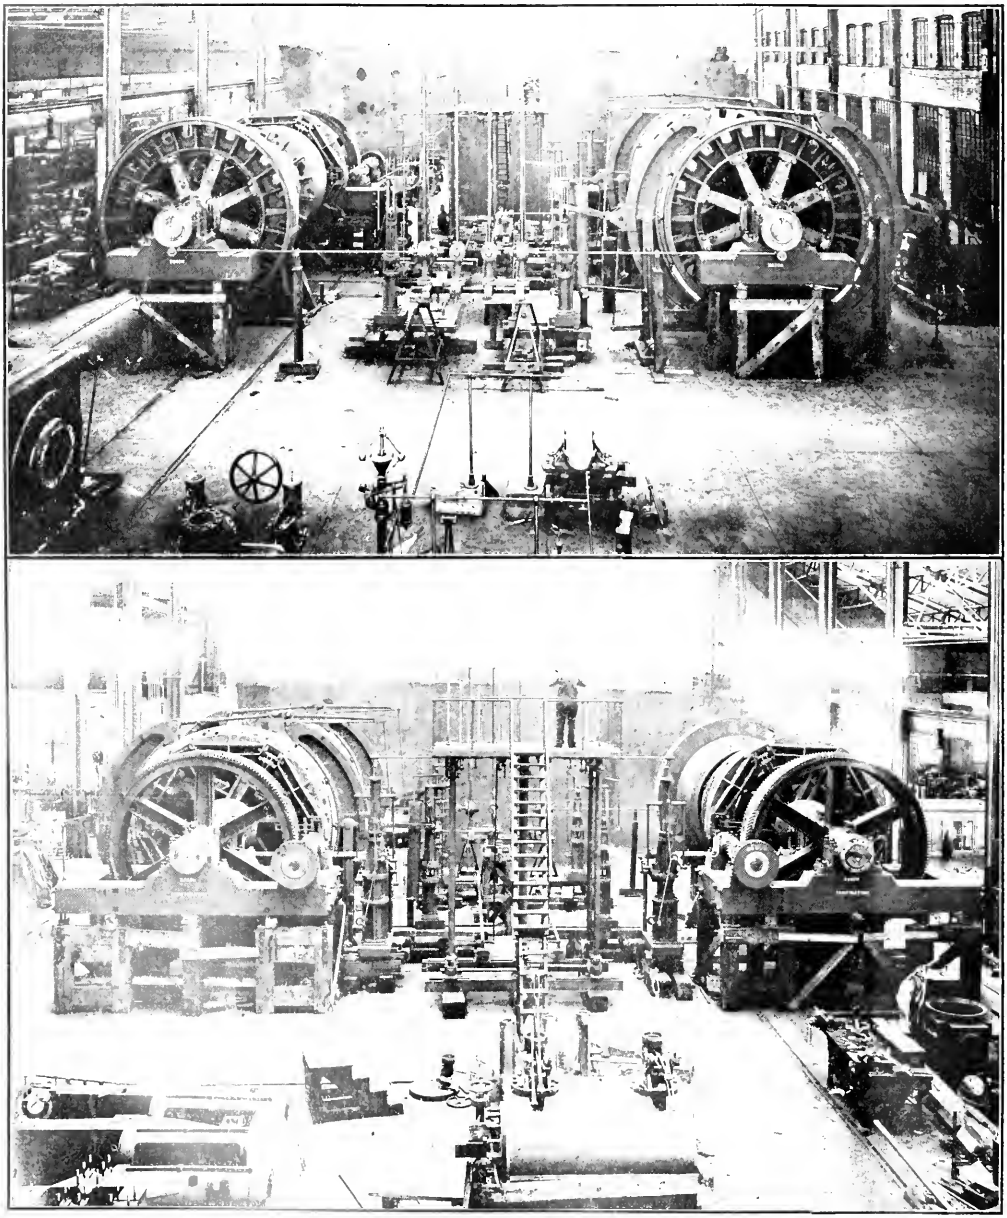
Prospecting Drill for Alaska Placers

The Flume Dredge Co., Mills Building, San Francisco, has designed a portable drill especially to meet the requirements of prospecting dredging ground in Alaska, built for it in the shops of the Straub Manufacturing Co., Third Street, Oakland, Calif. Fifteen of them have been installed in Alaska and the demand for the drills is increased by the simplicity of handling, setting up and operating. The total weight of this drill, including poles, casing, etc., is 1300 lb. The shear legs are 16 ft. long. The hammer weighs 200 lb. Operation of the stroke is caused by winding the drill rope on a gypsy turned by the engine, which is a 4-hp. distillate engine, stationary on the drill. Casing is usually 4 in., which is considered the most practical, but 5-in. casing can be used. The drill is designed to dig 22 ft.; but the essential digging depth in Alaska dredging fields is usually less. The whole is mounted on wheels for moving and the wheels are removed when the drill is set for action. Two men easily wheel the drill about, set it up and operate it, and can put down six holes in a working day. The accompanying photographs show the drill mounted on wheels ready for transporting to the field, and also set up for actual drilling.

PROSPECTING DRILL READY TO BE MOVED

DRILL SET UP FOR OPERATION IN THE FIELD

Photographs from the Field

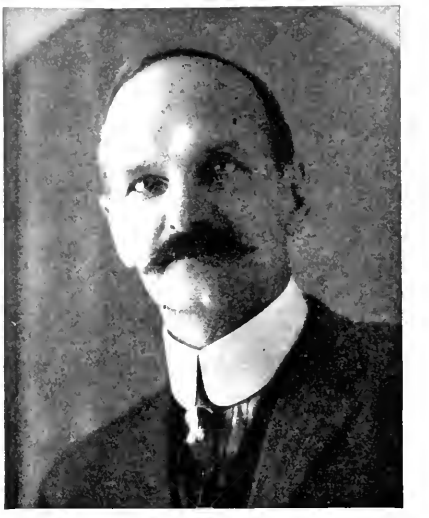


INSPIRATION CONSOLIDATED COPPER CO.'S ELECTRIC HOIST ASSEMBLED IN THE SHOP

This hoist, built by the Nordberg Manufacturing Co., Milwaukee, Wis., has double 10-ft. drums, 65-in. face, and carries on each 100° lay of 1¼-in. rope. Rope pull is 10,850 lb., hoisting normally in balance with a rope speed of 750 ft. per min.

Mining Men in the Public Eye

CHARLES HAYDEN

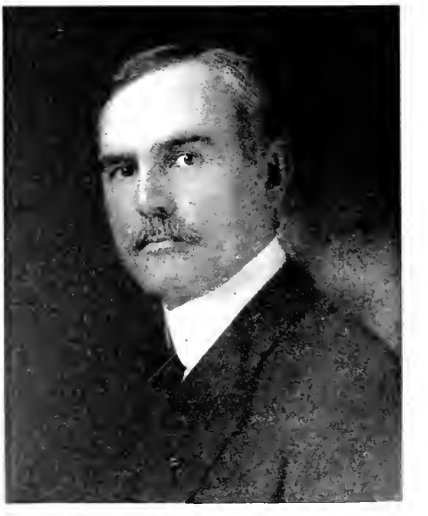


T. COLEMAN DU PONT

Messrs. Hayden and du Pont, together with S. Pierre du Pont, recently gave $250,000 to the Massachusetts Institute of Technology for a mining building, thus contributing to the maintenance of the prestige of the Institute, of which these three men are distinguished alumni

H. M. WILSON

Mr. Wilson recently retired from the position of engineer in charge of the Pittsburgh Station of the United States Bureau of Mines to become director of the department of inspection and safety of the Workmen's Compensation Insurance for Coal Mines



JOHN D. RYAN

Mr. Ryan lately became president of the [illegible] company, which displaces Amalgamated, and is the leader of Montana's industries. Indeed, it would be no stretch of the truth to characterize him as the leader of the copper-producing industry of the United States

Zinc and Lead Imports

An advance report from the Department of Commerce gives the imports and exports of zinc for the United States in the month of May as below, in pounds:

Imports from:	Ore: Gross Tons	Ore: Contents, Lb.	Metal, Lb.	Total, Lb.
Canada	744	616,600	11,693	628,293
Mexico	4,568	2,924,979	423	2,925,402
Australia	6,974	5,740,000	..	5,740,000
Cuba		.....	12,167	12,167
Brazil		.....	29,536	29,536
Uruguay		.....	69,467	69,467
Total	12,286	9,281,579	123,286	9,404,865
Zinc dust, Germany		.....	99,092	99,092

Exports:	Domestic Lb.	Foreign Re-exported, Lb.	Total, Lb.
Blocks, pigs, sheets, etc.	15,270,854	2,207,903	17,479,757
Zinc dross	1,147,385		1,147,385
Zinc dust	...	7,168	7,168

In addition manufactures of zinc to the value of $444,968 were exported. No exports of ore are reported. In May, 1914, the exports of domestic material were 214,201 lb. metal and 1436 tons ore, contents not reported; reëxports of foreign material were 224,000 lb. in ore and 3420 lb. zinc dust. For the five months ended May 31, the total exports of zinc metal, excluding contents of ore, were 588 short tons in 1914 and 59,263 tons in 1915; an increase of 58,675 tons this year.

Lead Imports

The statement gives the imports of lead into the United States in May as below, in pounds:

From	In Ore, Lb.	In Base Bullion, Lb.	Total, Lb.
England	54,320	...	54,320
Canada	143,000	...	143,000
Mexico	406,516	10,913,000	11,319,516
Chile	1,009,457		1,009,457
Peru	24,155	18,088	42,243
Total	1,637,448	10,931,088	12,568,536
Pigs, bars and scrap		...	1,480
Total lead imports		...	12,570,016

The total weight of ore imported was 1812 tons; of base bullion, 11,119,282 lb. Total imports of lead in May, 1914, were 5,619,050 lb.; in May, 1913 they were 8,822,722 lb. For the five months ended May 31 the total imports were 10,346 short tons in 1914, and 28,607 in 1915; an increase of 18,261 tons this year.

Shuman-Boys Sun-Power Plant at Meadi, Egypt

The history of the utilization of solar energy is outlined briefly by A. S. E. Ackermann (*Journ.* Roy. Soc. Arts, 1915, 63, 538-565; abst. *Journ.* Soc. Chem. Ind., May 31, 1915). Special reference is made to investigations culminating in the establishment of the Shuman-Boys sun-power plant at Meadi, near Cairo, during 1912 and 1913. This apparatus consists of five parallel units arranged with their axes N and S and mounted so as to "follow the sun" automatically. Each unit, 205 ft. long, is composed of a boiler placed on edge in a channel-shaped reflector of parabolic cross-section; and each boiler, placed at the focus of its reflector, is surrounded by an air space enclosed by a single thickness of glass. The total area of sunshine collected is 13,269 sq.ft., the concentration effected by the reflectors being 14½ to 1. In an extended series of trials made with this plant, the maximum quantity of steam produced was 12 lb. per 100 sq.ft. of sunshine per hour, or 183 sq.ft. of sunshine per b.hp. (1 b.hp. = 22 lb. of steam at atmospheric pressure); the maximum thermal efficiency was 40.1% (solar constant = 7.12 B.t.u. per sq.ft. per min.). In the best 1-hr. run, 1442 lb. of steam at atmospheric pressure was produced. The utilization of solar energy is regarded as almost a solved problem where sunshine is plentiful and coal only obtainable at about $17 per ton.

Australian Action on German Ore Contracts

The speech of Attorney-General W. M. Hughes of Australia, at the second reading of the Enemy Contracts Annulment bill introduced in the Commonwealth Parliament on May 5, is reported by the London *Mining Journal*, in part, as follows:

"The effect of war on contracts is to suspend some and terminate others, according to their nature. Some contracts are not contracts between enemies of the Empire, but between British subjects, but they are nevertheless contracts for the benefit of the enemy. These latter contracts are not affected legally by the war, but great uncertainty prevails as to the effect of the war on contracts, and it is to remove these uncertainties that the measure is introduced.

"It was impossible to tell what Germany was doing with regard to contracts, but if what was heard was to be believed, there could be no doubt that contracts were being voided, as well as the rights of private individuals. This bill cannot be judged fairly unless it is looked at in the lurid glow that rises from the gigantic battle in which the hosts of Christendom have arrayed themselves for the purpose of mutual destruction. It is a world-war, which is being waged for world-power—power that is not military power alone. It is waged by Germany for achieving commercial and industrial domination of the earth.

"The position is this: The mining companies of Australia, at least the majority of them, had entered into contracts for the disposal of their products up to the year 1921. In many of these contracts there are clauses which suspend them during the period of war, but which, after the termination of the war, enable the period of the duration of the war to be added to the term of the contracts. Thus, in a contract extending to 1921, a three years' war would mean that the contract would be extended to stretch out until 1924. Whether any of those contracts are discharged by the war I am unable to say. There is uncertainty and doubt about it all, and that uncertainty affects, not only the present operations of mining companies, but their future development, for no English capitalist would, for instance, invest money in a smelting works unless he was assured of a continued supply of metal.

Alleged German Domination of Markets

"The other way in which the position is affected is because these companies are unable to divert their produce from Germany, not only owing to contracts relating to supplies of metal, but because they have contracts for the sale of their metals which prevent them selling except through recognized persons and authorities. The price of lead today is fixed by the same people who fixed it before the war, although they are not outwardly the

same people. Every pound of lead the Admiralty or the War Office buys has to be bought through that one channel, and through that channel alone. The position originated with a German firm at Frankfort-on-Main, a firm whose methods were typical of the German character—systematic, thorough, and far-reaching. This German firm, or group of firms, exercised its powers in every important country of the world. The Metallgesellschaft, the American Metal Co., and the Australian Metal Co., were practically one and the same firm. The Australian Metal Co. is a company registered in Australia, though to all intents and purposes it is an offshoot of the one great concern. In London, the name of the firm is Merton, but Merton, though registered in London, is only one branch of the same power.

"The Broken Hill Proprietary has contracted to supply the Australian Metal Co. with its ores; that is an official fact. The greater number of that company's shares are held by Germans. The output of lead is still controlled by the Lead Convention, which is essentially German. The German element in London practically controls the sale of metal. Merton is the only selling agent for lead, and it is a fact that British buyers have been refused supplies since the outbreak of war because sellers are bound to Merton.

Legislation Necessary to Cancel German Contracts

"There is not the shadow of doubt that nothing but the sharp edge of legislation can cut the contracts which bind Australian commercial men to the agreements they have entered into. The Broken Hill Proprietary Co. has given notice of its intention to annul its contracts. But it does not know its position in law; neither does anyone else.

"The Government does not propose to act against the interests of any of the Australian companies. Just the opposite. The Government intends to use all the power in its possession to bring about a termination of German influence in Australian trade. The Broken Hill Proprietary Co. has undertaken to give three months' notice to sever its connection with the companies influenced by Germans or German capital, but the mere giving of notice does not legally terminate the agreement. Elder, Smith & Co. have also 'broken contracts,' but are still liable.

"The firm of Merton's, British in origin as well as name, is merely the conduit pipe through which the profits are taken to Germany. The Government has ample proof of that. The bill provides that all enemy contracts shall be null and void. It provides also, in Section 4, for another class of contracts—that is, for contracts that can be determined if one of the contracting parties so desires. That is to meet the case where war has made it impossible to carry out certain of the conditions agreed on."

[The above summary of Mr. Hughes' speech outlines what it is proposed to do in Australia with respect to the disputed ore contracts. There are not a few inaccuracies of statement contained in it. It should be remarked also that the Lead Convention, in which the American Smelting & Refining Co. and the Spanish producers were participants, was disrupted July 1 by the secession of the Australian producers.—Editor.]

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

AGGLOMERATING—Treatment of Subdivided Ores for Agglomerating or Reducing Them and Apparatus Therefor. Gustaf Grondal, Djursholm, and Herman Nilsson, Nyhammar, Sweden. (U. S. No. 1,142,324; June 8, 1915.)

ALUMINUM NITRIDE—Process for the Manufacture of Aluminum Nitride. Paul Bunet, Whitney, N. C., assignor to Société Generale des Nitrures, Paris, France. (U. S. No. 1,145,747; July 6, 1915.)

ALUMINUM SOLDER. Jonas F. Gross, Allentown, Penn. (U. S. No. 1,145,307; July 6, 1915.)

ASBESTOS PACKING. Alexander Warrell, St. John, N. B., Canada, assignor to Continental Asbestos Corporation, Worcester, Mass. (U. S. No. 1,143,153; June 15, 1915.)

CONCENTRATION—Improved Apparatus for the Water Concentration of Ores or the Like. W. M. Martin, Redruth, Cornwall. (Brit. No. 2844 of 1915.)

CONCENTRATOR—Ore Concentrator. Joseph Weatherby, New Cumberland, Penn., assignor to Electric Ore Separator Co., New Cumberland, Penn. (U. S. No. 1,145,046; July 6, 1915.)

CONDENSER for Zinc and Lead Vapors. Edvin Andreas Johansson, Trollhättan, Sweden. (U. S. No. 1,145,685; July 6, 1915.)

COPPER MATTE—Improvements in the Process of Bessemerizing Copper Matte. J. B. Herreshoff, Richmond Hill, N. Y. (Brit. Nos. 12,916 of 1914 and 2219 of 1915.)

CRUSHER—Stone Crusher and Pulverizer. Edgar B. Symons, Milwaukee, Wis. (U. S. No. 1,145,629; July 6, 1915.)

CRUSHING—Improved Apparatus for Feeding Ores to Stamping Batteries and Other Pulverizers and Mixers. H. Standen, Zuitspanburg, Transvaal. (Brit. No. 18,622 of 1914.)

CUPOLA FURNACE. Michael Zippler, Jr., Pittsburgh, Penn. (U. S. No. 1,145,648; July 6, 1915.)

DREDGES — Floating Discharge Pipe for Hydraulic Dredges. Arthur Wells Robinson, Montreal, Quebec. (U. S. No. 1,143,321; June 15, 1915.)

DRILL—Core Drill. Clinton E. Wilder, Erie, Penn., assignor to National Forge & Tool Co., Erie, Penn. (U. S. No. 1,145,822; July 6, 1915.)

DRILL—Pulsatory Percussive Drill. Lewis Condict Bayles, Easton, Penn., assignor to Ingersoll-Rand Co., New York, N. Y. (U. S. No. 1,144,990; July 6, 1915.)

DRILLS—Exhaust-Closing Valve for Hollow Steel Percussive Drills. Lewis Condict Bayles, Easton, Penn., assignor to Ingersoll-Rand Co., Jersey City, N. J. (U. S. No. 1,144,991; July 6, 1915.)

DRILLS—Core Holder for Tubular Rock Drills. John F. Lindberg, Hibbing, Minn. (U. S. No. 1,145,323; July 6, 1915.)

ELECTRIC FURNACE. Paul Bunet, Whitney, N. C., assignor to Société Generale des Nitrures, Paris, France. (U. S. No. 1,145,748; July 6, 1915.)

GRAPHITE—Process of Purifying Graphite. Edouard Napoléon Lainé, Paris, France. (U. S. No. 1,145,924; July 6, 1915.)

HAULAGE—Improved System of Electric Signs for Main and Tail Haulage in Mine and Like Places. G. B. Burrows, Wellingham, Durham, Eng. (Brit. No. 13,310 of 1914.)

HOISTING—Improvements in Safety Devices for Mine Cages. E. Tillack, Berlin, Germany. (Brit. No. 20,254 of 1913.)

LEVELING INSTRUMENT for Use in Underground Workings. James Graham Bower, Johannesburg, Transvaal, South Africa. (U. S. No. 1,145,664; July 6, 1915.)

MINE-CAR WHEEL and Axle. Frederick A. Sweet, Salt Lake City, Utah. (U. S. No. 1,141,990; June 8, 1915.)

MINE DOOR—Electrically Operated Mine Door. William W. Murray and James F. Dillon, Dearing, W. Va. (U. S. No. 1,145,787; July 6, 1915.)

NITRATE OF SODA—A Two-Stage Evaporation Process for Recovering Nitrate of Soda from Liquors Containing It and Sodium Chloride in Solution, and an Apparatus for Carrying Out Such Process. Gibbs & Co., Valparaiso, Chile; Kestner Evaporator Engineering Co., Ltd., London. (Brit. No. 12,475 of 1914.)

NITROGEN OXIDES—Improvements in the Manufacture of Oxides of Nitrogen and of Catalysts to Be Employed in Such Manufacture. Badische Anilin & Soda Fabrik, Ludsvigshafen-on-Rhine, Germany. (Brit. No. 13,848 of 1914.)

PERCUSSIVE TOOL—Pulsator-Driven Percussive Tool. Arthur H. Gibson, Easton, Penn., assignor to Ingersoll-Rand Co., New York, N. Y. (U. S. No. 1,142,514; June 8, 1915.)

SULPHIDE ORES—Process of Treating Mixed Sulphide Ores. Erich Langguth, Neerpelt, Belgium. (U. S. No. 1,144,481; June 29, 1915.)

WELDING—Electric Welding and Fusion Deposition of Metals. Arthur Percy Strohmenger, Westminster, London, England, assignor to Slaughter & Co., Ltd., London, England. (U. S No. 1,144,390; June 29, 1915.)

ZINC—Mechanism for Removing Residue from Vertical Retorts. Alexander Roitzheim and Wilhelm Remy, Duisburg-Ruhrort, Germany. (U. S. No. 1,144,065; June 22, 1915.)

ZINC—Method of Smelting Zinc and Other Ores. James M. Hyde, Berkeley, Calif. (U. S. No. 1,144,037; June 22, 1915.)

ZINC-SMELTING FURNACE. James M. Hyde, Berkeley, Calif. (U. S. No. 1,144,036; June 22, 1915.)

ZINC SULPHATE—Production of Zinc Sulphate. Ramon Bonastre Llopart, Cordoba, Argentina. (U. S. No. 1,140,354; May 25, 1915.)

Correspondence and Discussion

Which Is the More Useful—Steam or Explosives?

Say dynamite to the average man and he turns pale and gets ready to run; say it to the average woman and she shrieks.

Dynamite is not a gentle creature. It is always ready for a fight and it's a hard hitter. Jess Willard isn't in old Bill Dynamite's class as a biffer. Few people realize how indispensable a commodity dynamite really is. In Philadelphia recently a debate was held, the subject being: "Which is the more useful to mankind—steam or explosives?"

At first thought, ninety-nine people out of a hundred would answer without a moment's hesitation:

"Why, steam, of course; how could we do without it? It's the motive power of our passenger and freight trains; of our mills and factories; it heats our apartments and it propels our steamboats. Without it, manufacturing and shipping—the most important industries of the world—would stop.

"And dynamite—why all that's good for is to enable burglars to blow up safes and anarchists to destroy buildings."

Yes, that's the average thoughtless, uninformed person's idea of the high explosive. But not so fast. A little investigation, a little thought discloses that there is much to be said on the other side of the question. The debate isn't so one-sided as it might appear.

What is steam? A vapor generated by superheating water. How is it heated? By burning coal under the boiler. By what means is the coal obtained? By blasting with explosives. All right, then score one for the "big noise"; without it we would not have coal in sufficient supply to generate steam equal to the commercial requirements of modern times. Thus it would appear steam is dependent upon explosives.

Ores from which are made the raw materials most largely used in many of the mills and factories are equally dependent upon explosives for their production. Therefore, without explosives, many of the mills now in active operation would not exist.

And the passenger and freight trains. The locomotives are made of iron and steel, the ores for making which are mined with explosives; the coal that furnishes their power is mined with explosives. Sections of roadbeds on which they run were blasted through rock with explosives; the rails were made from ores which were mined with explosives; the ballast was quarried with explosives; the bridges along the lines are made of steel, made from ores, mined with explosives. Could we do without them?

And now as to steam. Electric locomotives will do nearly everything steam engines will do. They will pull the passenger and freight trains, and electric motors will run the machinery in mills and factories. There are many hydro-electric plants in the country and water power is available for many more.

Recently, dynamite has begun to play an important part in agriculture. Before the seed is planted, before the surface is even plowed, the subsoil is broken up by blasting, the idea being to improve drainage, aeration and increase the water-storage capacity of the soil. The holes in which nursery stock is planted are blasted to improve drainage, aeration and moisture storage and to enable the roots to spread out in the soil normally and easily.

Ditches are blasted with dynamite, drainage sink-holes are put down and stumps and boulders encumbering farm land are disposed of with it. Many millions of pounds yearly are used for these agricultural purposes.

Now, if we really had to do without one of them, could we not do without steam better than without explosives?

F. W. Wilson.

Wilmington, Del., July 8, 1915.

Classification of Technical Literature

The Joint Committee on Classification of Technical Literature is extremely desirous of obtaining the assistance of the *Journal* readers in making a collection of classifications of applied science which have been developed independently in the offices of manufacturing plants or engineering firms, especially those which exist in manuscript form, and have been used for filing or indexing data.

The committee would especially like to have copies of any extensions of present systems pertaining to any special industry or branch of engineering not now fully covered by the published classifications. Send data to 29 West 39th St.

W. P. Cutter.

New York, June 21, 1915.

Gold Dredging in Philippines

May I call attention to a slight error in the matter of fixing credit for an article on gold dredging in the Philippine Islands which appeared in the *Journal* of Apr. 17, 1915, p. 685, and was credited to the *Philippine Journal of Science?*

The original article was published through the courtesy of William Kane, the author, in the "Mineral Resources of the Philippine Islands" for the year 1913. The "Mineral Resources of the Philippine Islands" is an annual publication of the Division of Mines, Bureau of Science, Manila, P. I. It is distributed free of charge and reaches a different set of readers than the *Philippine Journal of Science*—to which all divisions of the Bureau of Science contribute. It is true that papers are occasionally published in both periodicals, but I believe that Mr. Kane's data appeared only in the "Mineral Resources of the Phillippine Islands."

Wallace E. Pratt.

Manila, P. I., June 7, 1915.

Editorials

Position of the Steel Industry

From present indications the steel industry of the United States, which for nearly two years has been passing through a period of great depression, is now well started on the up-grade. It was generally believed that the lowest point had been touched early in 1914, when the reaction caused by the overproduction of the previous year had nearly reached its limit, and prospects had begun to improve, when the outbreak of war disorganized all business temporarily and left the trade in worse condition than it had ever been. About November last the depression was greatest and production was at the lowest level.

Matters began to revive slowly and production to increase as domestic demands gradually improved; but as spring advanced, it became evident that the great war, which had for a time helped to depress our steel manufacturers, was going to give them some important aid in starting the revival. Foreign orders were booked at an increasing rate. Not all of them were for finished war material; many of them were for the iron and steel needed for making such material elsewhere, and many for railroad equipment and track material. Just how large a proportion of the increase of business is due to these war orders it is difficult to say. Not all of them are made public, and in some cases the recipients do not care to make the sources known. It is quite plain, however, that they have had much to do with the present revival of trade.

The value of the iron and steel exports has been creeping up. In the month of May the total tonnage of exports was 262,844 tons, against 138,514 tons in May, 1914—an increase of a little more than 90% being shown. It is probable that later months will show an equal—possibly a larger—gain.

War orders or foreign orders have not been the only source of improvement in the iron trade. There has been a fairly steady gain in the demand from domestic consumers, notwithstanding the fact that large construction enterprises have been rather slow, and that buying by the railroads has been on a moderate scale only, at least on the surface. The rate of operation of the mills has been gradually increasing, until at present it is approaching full capacity in most of the mills in the Central West. The Steel Corporation's monthly reports—which are generally considered an index to the condition of the trade—in June showed a noteworthy increase, indicating a large excess of orders over deliveries. The chief independent producers are in much the same condition.

To go back to the foundation, the production of pig iron, which was at its lowest point in January—at the rate of 57,200 tons daily, or about 20,850,000 tons yearly—has advanced month by month until on July 1 the make of pig iron was 81,300 tons daily, or at the rate of 29,650,000 tons a year. Notwithstanding this gain in the rate of production, the total make for the first half of 1915 was almost the same as the first half of 1914, the estimated total this year being 12,248,000 tons, while the completed report in 1914 gave 12,536,000 tons for the first half. For the second half of 1914 the actual make was only 10,796,000 tons, and the present indications are that the current six months will show a much higher figure than that. It does not seem probable, however, that the total for 1915 will reach the high point of 30,966,000 tons attained in 1913, though it may approximate it closely if the present rush continues.

The demand during the present year has been mainly for steel products, and the increase in pig-iron production has come chiefly from the steel-works furnaces. There has been complaint all along from the merchant furnaces that make pig iron for sale, that their market was slow and dragging behind the steel market. They also claimed that while the steel makers had been able to advance their prices from time to time and were securing from 15 to 25% more money for their product than they received at the opening of the year, pig-iron prices remained at a low level, and that it was hard to secure any advance. There seems to be ground for this contention. The general rate of production has advanced over 40% since January. That of the merchant furnaces has increased from about 16,000 tons a day in January to 20,500 in July, or less than 30%, while prices have remained low because a number of furnaces are ready to start at the first indication of improvement.

The demand, as has been stated, has been for finished steel, and so far the steel companies have been able to supply it from their own stocks without buying from outside makers. The foundry trade, on which the merchant furnaces largely depend, has been much slower to respond to improvement, as is indeed usually the case after a time of depression. Nevertheless, their position has not been altogether bad. Lake ore and coke prices have been cheap, and costs as well as selling prices have been low. It looks now as if the improvement in the pig-iron market was nearly due and that it would shortly follow the course upon which steel has already started so actively. In fact the present week brings reports of some large purchases of both bessemer and basic pig from outside furnaces, made by large steel companies.

Chromium Supplies Limited

There is probably going to be a scarcity in chromium and chromium compounds soon. The supplies of this material ordinarily come from New Caledonia, Turkey and Rhodesia. The Rhodesian and New Caledonian supplies have probably been commandeered to supply France and Great Britain. Turkish commerce is in eclipse. We know of only one mine operating in this country and two more which might be operated. As we understand that some of the brick manufacturers have notified their customers that they can only supply chrome brick for a little while longer and that some shapes already cannot be obtained, it would appear that the man with a chromium prospect might profitably spend some money on exploration and further development.

Increased Zinc Smelting Capacity

As the price of spelter moved upward during the first half of 1915, surpassing the price for copper, the *Journal* prophesied that the conditions would inevitably develop an increase in spelter production, and especially that this would be brought about by smelters adding furnaces to their plants. In previous reviews of the situation it was not considered likely that new works would be built, in view of the general opinion that the existing conditions would be so ephemeral that it would be unsafe to enter upon the construction of new plants and that no one would be likely to do so, having in mind the long time bound to elapse before production could be begun. These forecasts have been borne out in the main, as has been chronicled in this paper, but they were at fault in not reckoning upon the surprising number of supposedly defunct plants that have been restored to usefulness—some of them after idleness of 15 years—and there are two new plants being built. With respect to the latter, one is being built in Oklahoma by George E. Nicholson—an experienced and successful smelter—who appears to be able to build zinc smelteries in a marvelously brief time; and the other is a great plant that has been started at Donora, Penn., by the United States Steel Corporation.

The Donora plant has probably been planned less as a means of reaping fabulous profits out of the present extraordinary situation than as a method of insuring the supply of the largest consumer of spelter and relieving it from the vagaries and vicissitudes of a troublesome market. It will be a modern, efficient and substantial plant, wherefore its construction period will be lengthy and its production may not begin until spelter has regained a more nearly normal level. However, the construction is being pushed ahead vigorously and a large supply of Australian zinc ore has already been contracted for, indicating that no great delay in the ability to convert it into spelter is anticipated.

It is useful now to summarize what the recent and the prospective additions to smelting capacity amount to. At the first of this year it was estimated that the United States possessed a smelting capacity for producing about 500,000 tons of spelter in a year, that capacity being classified as active, operated irregularly, inactive, and new—the total number of retorts being about 120,000. In the inactive class were not included several old plants in Kansas and Missouri, most of which had been idle for more than 10 years.

At the middle of 1915, all of the smelting capacity listed at the beginning of the year was in use, and there had been revivals and additions—consummated and in process—of about 14,000 retorts, corresponding to about 60,000 tons of spelter a year. Adding to this the 40,000 tons that Donora is expected to produce, there is now in sight the means for making 100,000 tons more spelter annually than there was six months ago.

As to the status of this new capacity for production, a fairly large part of it is already available; another large part is expected to be ready by the end of August; the new Nicholson works will probably be fired up by October; Donora will surely not be ready until some time in 1916.

It may be assumed that the production of spelter in the United States is at present at the rate of 500,000 tons per year and that in the fourth quarter it will be at least at the rate of 560,000 tons per annum. Incidentally it may be remarked that the entrance of new companies—large and small—into the business is prima facie evidence that no combination in restraint of trade exists in this industry, as has always been known by every well-informed person. The ore supply is bountiful, as is reflected by the wide smelting margin that continues to exist. Miners have difficulty in placing their ore rather than do smelters find trouble in getting what they need. Of course many of the smelteries that have lately been put in operation are uneconomical and a large margin is necessary for anybody to be able to operate them. A return to normal conditions will extinguish them, as a strong wind blows out a candle.

Explosives Used in Mining

No one of the implements of his profession is shrouded in more mystery than the explosives which the mining engineer uses in his work. Originally this was due to the disinclination of competing manufacturers to give out any technical data relative to their product. The subject is still very much clouded by the sales policy of various companies and the idiosyncrasies of the many powder salesmen in the field. There are now so many brands of dynamite on the market, and there is so little correlated information at hand on the subject, that the buyer of dynamite is almost wholly at the mercy of the powder salesman or of a mine superintendent "wedded" to a particular brand.

It is an everyday occurrence for the salesman to advocate the use of some brand because, for instance, it has low-freezing properties or because it makes less gas, either one of which troubles may be giving the mine management a lot of worry. Because the mining engineer has been afforded no opportunity properly to compare and study the various classes of dynamite, he has had to rely largely on the salesman for such information, and frequently he has gone astray.

Very elaborate and artistic trade publications issued by dynamite manufacturers, while full of interesting and valuable information, fail to "fill the bill" despite the promise of their attractive exteriors. The Bureau of Mines has done much by analyses, tests and experiments to disseminate this much-needed information, but unfortunately its results are scattered through a considerable number of publications and the valuable nuggets of information therein are buried in a mass of repetition and information on extraneous subjects, which makes a lot of research necessary to get the benefits of their valuable work.

The day of indiscriminate dependence upon what the powder salesman thinks he knows is past, at least for the larger companies, and it is not too much to hope that it is nearly over for all companies that have progressive management. The cost of the explosives, the time lost waiting for powder smoke to get out of the working headings, the danger of asphyxiation from noxious gases, not to mention the disruptive effect of the powder itself, are each important enough to secure for this problem the attention and study which it deserves and which it has too long been denied.

BY THE WAY

Dispatches of July 16 announce the arrest of George S. Speets in Berlin. Speets had an American passport and was alleged to be doing a general brokerage business in American copper. If he were really selling American copper there, a number of people here would like to know how he did it. There seems, however, to be some doubt about Speets' copper sales, his citizenship, and his passport, all of which have been under investigation by Ambassador Gerard, as well as by the German Government.

Among the war news of the day is the report that the famous old bronze lion that stood on the battlefield of Waterloo has been pulled down and is being converted into German shells. The "Lion of Waterloo" was cast by Cockerill of Seraing, and stood on a mound 200 ft. high, marking the spot where the Prince of Orange was wounded in battle. It was made of the metal of captured French cannon and weighed 28 tons. Another writer calls attention to the fact that if the Germans had really taken the Belgian lion at Waterloo to make shells, it was only a final episode in a sad career. A few years after the famous battle, French troops marching to the siege of Antwerp deprived him of his tail.

The New York *Evening Post* of July 17 expressed the following appreciation of Doctor Holmes and his work:

A tribute of unusual and touching character is being paid today to the memory of a life of rare beneficence and self-sacrifice. Coal mines will be closed throughout western Pennsylvania and West Virginia, and owners and miners will do homage to the devoted labors of Joseph Austin Holmes, director of the United States Bureau of Mines, in behalf of the health and safety of the mine workers. Doctor Holmes' death last Tuesday, at the age of 55, was directly traceable to his zeal in this work, which led him, in the pursuit of his researches, to expose himself personally to those dangers and hardships which it was his purpose to avert or reduce to a minimum. Both as an administrative organizer and as a scientific investigator, his endeavors have borne rich fruit in the improvement of conditions and the perfecting of safety appliances. His death from tuberculosis must be set down as a result of overwork under conditions which would have been trying to a more robust constitution. It is in the contemplation of lives like this, sad as is the sense of loss, that one is heartened by the realization of the great store of unselfish devotion that is being unobtrusively expended by hundreds of quiet workers, in public and private station, for the betterment of the lot of mankind.

Real get-rich-quick schemes differ from the "get-rich-quick" variety in several ways, most prominent among which is the offer on the part of promoters of the latter to share the great benefits with the public at large. This seems to be the difficulty with the Nevin Electric Survey Co., the shares of which are now being offered to the public at 75c. each. The officers of the company are said to be men of the highest financial standing, but so generous that they wish to share with the public the great emolument that is to be received for the discovery of mineral deposits through the instrumentality of an electrical device invented by James E. Nevin. Mr. Nevin is quoted as saying that with this device "any deposit of matter contained in the earth can be defined with great accuracy as to area, depth and thickness of the deposit." Doubtless some people will buy the shares without stopping to think that anyone who could locate all the hidden deposits of gold, silver, copper, zinc, etc., would over night become the Pied Piper of the mining industry.

These are the greatest days the zinc miners have ever known—in more ways than one. Down in the Joplin district they are now finding ore in their dreams. Utah has long been known as the land of the revelator, and the story of the discovery of the Beck Tunnel mine by revelation is well known. That discovery proved so profitable that the principal owner secured a large following locally for the development of other Tintic mines, notably the Iron Blossom and the Colorado. But according to a Joplin dispatch, Missouri is now infringing on Utah's prerogative. The wife of one of the owners of the old Ethel S. mine, near Cooper Hollow, had a dream which, the dispatch states, is going to bring riches to the owners of that property. The mine is reported to have been paying fairly well until a few weeks ago, when the ore became very thin and finally gave out altogether. One morning Mrs. J. C. White told her husband, who owns a half interest in the Ethel S. mine, that she had dreamed of finding another great face of ore, but at the spot pointed out there was only a limestone wall. At night Mrs. White was lowered to the bottom of the mine, and while asleep she walked into the drift she had dreamed of. A single shot the next day broke "through the limestone wall into a great deposit of ore," and now the Ethel S. is the "Dream Lady" mine.

A writer in *World's Work* for July quotes Harry E. V. Brittain, one of the English founders of the Pilgrim Society, and who recently visited this country, as saying the following about H. C. Hoover and his Belgian relief work: "Do not think because we say little that we are not grateful. We know at home in England that to the American Commission for Relief in Belgium we owe the safety and the lives of the bulk of the Belgium nation. Our government takes the personal word of honor of your fellow-countryman, Mr. Hoover, as an international assurance in a way which has no precedent and no parallel in the history of peace or war. On the pledge of one American, we have allowed to go into Belgium millions of dollars' worth of food which would be of priceless military and other value to the Germans who occupy the country. Mr. Hoover, in the name of the commission, tells us this will go only to the Belgians. We take his word and have no reason to regret it. But our military and naval authorities would never be justified in taking the word, under the circumstances of a life-and-death struggle, of one American, or even of the American nation, unless they were convinced that with it went the power and ability to 'make good.' We have found that you are as good as your word. Your flag has safeguarded more relief than the philanthropy of the whole world ever dreamed it would be asked to supply. Under the Star and Stripes a distressed civilian army, greater than the combined militant armies of France and Germany, is being kept alive. Impelled by humanity and guided by an efficiency that is the envy of every European government, you have pierced the lines of all armies, broken all blockades, and gained the first really decisive victory of the war."

PERSONALS

C. W. Purington has gone to Petrograd on his way to the Lena district, Siberia.

W. H. Staver recently examined and sampled the Suffolk mine near Ophir, Colorado.

Roy C. McKenna has been elected president of the Vanadium Alloys Steel Co., Pittsburgh, in place of E. T. Edwards.

Faris V. Bush, of Lordsburg, N. M., one of the New Mexico contributors to the "Journal", has been chosen a director in the Arizona Eastern Ry. Co.

C. W. Wright, the general manager of important lead mines in Sardinia, has arrived in this country for his annual visit. He will return to Sardinia in September.

James Bowron, president of the Gulf States Steel Co., and a pioneer among Alabama iron men, is making an extended trip through the North, and expects to visit Alaska.

Lawrence H. Underwood, late with the Indiana Steel Co., at Gary, has been appointed superintendent of the byproduct coke plant of the Youngstown Sheet & Tool Co., at Youngstown, Ohio.

James McEvoy, formerly of the Canadian Geological Survey and more recently manager of the Crow's Nest Pass Coal Co., has become attached to the Canadian expeditionary forces as instructor in engineering.

J. F. McNamara has been appointed general manager of the Bayonne Castings Co., Bayonne, N. J., which puts the Monel metal made at the Orford Copper Co. works, in finished form. He succeeds W. E. Oakley, resigned.

E. Hampton, superintendent of the Bunker Hill mine, Amador City, Calif., has recovered from his recent illness and is again in charge of the mine. E. C. Clark who was in charge during Mr. Hampton's sickness has gone to Nevada.

Eugene C. Templeton, a graduate of Stanford University in 1910, has taken a position with the Irtysh Gold, Zinc & Lead Mining Co. in Siberia, and will leave for that country in a short time, expecting to remain at least one year.

Dr. Horace B. Patton, professor of geology in the Colorado School of Mines, is spending part of his vacation in California. He expects to undertake some field work in August in a survey of the Platoro-Jasper district, southern Colorado, for the U. S. Geological Survey.

Arthur Clark Terrill, who has been employed the past year as field representative of the New York State Museum collecting and placing on display the large mining exhibit representing the Empire State at the Panama-Pacific International Exposition, has been appointed head of the department of mining engineering in the school of engineering, Kansas University, Lawrence, Kansas, beginning with September.

OBITUARY

Cecil Chaplin, one of the pioneers of Tonopah and a partner of George Wingfield in opening the camp at Goldfield, died at Los Angeles, Calif., July 15, aged 60 years. He was also heavily interested in mining property in Montana.

Horatio Weber Baker, founder of the chair of mining engineering in the University of Nevada, died at San Francisco on July 8. For the past three years Mr. Baker was in the employ of the "Mining & Scientific Press" of San Francisco.

Judge J. P. Bradbury, who died at Pomeroy, Ohio, July 17, aged 77 years was well known as a lawyer and for a number of years judge of the Ohio Supreme Court. In his earlier days, however, he was an active gold miner in Utah and California.

Col. Jack Faw, a well known character in western North Carolina and Virginia, was killed July 14 at Jefferson, N. C., by the premature explosion of a blast. He was opening a mine there. He was 60 years old and had been a prospector and promoter for a number of years.

Prof. Frederick Prime died at Atlantic City, N. J., July 14, aged 65 years. He was born in Philadelphia, graduated from Columbia College, New York, in 1867 and later received degrees from Lafayette College and the Bergakademie at Freiberg, Germany. He was instructor in assaying at the Columbia School of Mines for some time and was professor of geology and metallurgy at Lafayette College for nine years. He was president of several iron and electrical companies in Alabama and Pennsylvania. In 1895 he was appointed professor of natural history at Girard College in Philadelphia and had since held that position. He was a manager of the Academy of Natural Sciences of Philadelphia and had been for some years one of the secretaries of the American Philosophical Society. He edited the English edition of Von Cotta's "Treatise on Ore Deposits."

Joseph Claybaugh Campbell died at San Francisco on July 1, from a ruptured blood vessel resulting from playing golf. Campbell was 63 years old, born in Oxford, Ohio. He studied for the bar at Frankfort, Ind., under his uncle Joseph Claybaugh, later a member of the Indiana Supreme Court. He had been in California for more than 40 years. In the early seventies he was elected district attorney of San Joaquin County. He served as chairman of the Republican State Central Committee and was once an aspirant to Congress. As an attorney he was identified with the Noyes-Alaska mining cases and was counsel for the defense in the Cœur d'Alene mining cases, and was chief attorney for Mayor Eugene Schmitz of San Francisco in the graft trials. He organized the law firm of Reddy, Campbell & Metson in San Francisco in 1889. At the time of his death the firm was known as Campbell, Weaver, Shelton & Levy.

SOCIETIES

American Institute of Mining Engineers—The Tintic trip of the Utah Section on July 15 was very successful and was attended by about 80 members and guests. After a welcome at Eureka by the mayor of that town, the members traveled around the district by automobiles and by the Knight railroad, going underground at the Mammoth, Silver City, Iron Blossom, Dragon Iron and Chief Consolidated mines. The banquet and a business meeting were held at Eureka in the evening, after which a dance and a moving picture show were given to the visitors. The party reached Salt Lake the next noon.

Lake Superior Mining Institute—The annual meeting for 1915 will be held Sept. 6-9. The first day will be spent on the Gogebic range, the second on the Cuyuna range and the third and fourth days in Minneapolis and St. Paul. This will be the first visit of the Institute to the Cuyuna. On the first day, a first-aid meet will be held at Ironwood under the charge of Edwin Higgins of the Bureau of Mines. Luther Brewer of Ironwood is general chairman of the Committee of Arrangements for the trip. L. M. Hardenburgh of Ironwood is president of the Institute this year and A. J. Yungbluth, of Ishpeming is secretary, as he has been for a number of years.

TRADE CATALOGS

Knox Motors Co., Springfield, Mass. Catalog. Tractors. 16 pp., illus., 9x12 inches.

International Nickel Co., 43 Exchange Place, New York. Catalog. Monel Metal. 12 pp., 4x8½ inches.

General Electric Co., Schenectady, N. Y. Bulletin No. 42,552. Motor Generator Sets. 28 pp., illus., 8x10½ inches.

Allis-Chalmers Mfg. Co., Milwaukee, Wis. Bulletin No. 1092. Synchronous Converters. 16 pp., illus., 8x10½ inches.

I. P. Morris Co., Beach & Ball St., Philadelphia, Penn. Bulletin No. 4. Hydraulic Turbines. 70 pp., illus., 8½x11½ inches.

Waterbury Co., 80 South St., New York. Catalog. Armored Wire Rope. 32 pp., illus., 3½x6 in. Catalog. Fiberclad Wire Rope. 24 pp., illus., 3½x6 inches.

American Roller Bearing Co., 416-20 Melwood Ave., Pittsburgh, Penn. Bulletin No. 1002. Roller bearings for power transmission devices. 4 pp., Illus., 7x10 inches.

Ingersoll-Rand Co., 11 Broadway, New York. Form No. 3031. Ingersoll-Rogler Class FR-1 Air Compressors. 24 pp., illus., 6x9 in. Form No. 4034. Leyner-Ingersoll Water Drill. 4 pp., illus., 6x9 inches.

The Chicago Pneumatic Tool Co. has issued Bulletin 34-X, relating to its Class A-G "Giant" gas and gasoline engines. The bulletin illustrates these engines in six sizes, ranging in horsepower from 16 to 130. The engines are similar in general design to the well-known Giant fuel-oil-driven engines manufactured by the same company with the exception that they are designed for operation with manufactured or natural gas.

Editorial Correspondence

SAN FRANCISCO—July 11

A Gold-Dredging Installation is contemplated on the Sältzer ranch, four miles south of Redding, by Lawrence Gardella of Oroville who is reported to have purchased the property. The Sältzers have owned the tract for 35 years. It contains 2150 acres of which 1500 acres of tillable ground is under ditch carrying 1700 in. A dam, said to have cost $5000, was built last year to replace the one constructed 35 years ago. Reported that Gardella will build a new hull and use machinery from one of his dredges to be dismantled at Oroville, where it has worked out its field. This tract of land is between Redding and the old Horsetown dredging field, and has been prospected for dredging, but no satisfactory negotiation had previously been reached. There is a large amount of good dredging ground in this section of Shasta County but from returns that are available it is believed that the gravel does not run to high values. This field is adaptable for small dredges of from 5- to 7½-cu.ft. bucket capacity, and is one of the numerous fields in California worked by early hydraulic and other placer-mining methods to shallow depths. But these fields are not inviting to large operators with dredges of 9- to 15-cu.ft. bucket capacity. They are not attractive for the further reason that the cubic-yard content of the ground, so far as has been prospected, is generally small compared to what has been recovered in many of the prominent dredging fields in the state.

Mount Lassen Eruptions reached the one hundred mark on May 31, at 10 o'clock in the morning. The 99th eruption occurred at five o'clock in the evening on the previous day. That of May 30 carried no mud. That of May 31 came from the new fissure on the northern slope, 500 ft. below the main fissure and it was reported from Hat Creek Valley that no further damage was done and no dust fell, nor was there any quaking of the earth. A rise of 8 in. in Hat Creek was not due to the eruption but to the fact that Big Springs were cleaned out by the Northern California Power Co. These springs are the main feeder of Hat Creek, supplying the creek with 3100 in. of water. The daily newspapers state that no fire was seen. This would give rise to the belief that during other eruptions fire had been seen. The red glow said to be visible on Mount Lassen at night is in fact the reflection of the setting sun. Other weird sights said to have been witnessed by people within 10 to 50 miles of the eruption were the results of sunshine and probably some moonshine. There has been no fire nor any red-hot fragments blown out by these fissure eruptions, nor has there been smoke. What has been claimed as ashes was really dust of the crumbled soft rocks and the supposed smoke is a combination of steam and dust and sulphur fumes. For the satisfaction of people who insist upon calling Mount Lassen a volcano, it may be classed as a mud volcano That the mud is hot when it is poured out on the hillside, is true enough; but it has never yet assumed the condition of lava. A great deal of damage has been done and naturally farmers are anxious to reclaim the land and the water. A number of citizens of Hat Creek Valley have asked the Redding Chamber of Commerce to indorse them in a petition to the Federal Government for aid on account of the damage done by the mud flow of May 22. At the time of making this request at Redding it was reported that the choking up of Big Springs by the mud flow had shut off the water in Hat Creek. That was true enough, but as has been stated, the springs have been cleaned out and with the aid that may be given by the county and possibly the Government the water supply need be no further disturbed and destruction to the land may be overcome by proper methods of reclamation. A number of visitors at the Exposition have indicated the purpose to visit Mount Lassen, which may be of interest to tourists and which is not likely to be at all dangerous at proper distance.

BUTTE—July 14

The Butte Miners' Union Has Won the Suit brought by the Western Federation. The Supreme Court of Montana handed down a decision June 6 in Helena in favor of the Butte Miners' Union in its long litigation with the officials of the Western Federation of Miners. The order of the district court, recently made, turning over the property of the local union to Guy Miller as representative of Charles H. Moyer and the Western Federations of which he is president, is annulled and the property of the union is again placed in the hands of the local officers. Property is valued at $100,000.

Horace V. Winchell has been in Butte the past week creating interest in the special meeting of the Mining and Metallurgical Society of America, which will be held in Washington, D. C., Dec. 16. Mr. Winchell is chairman of the mining-law committee of the society and Charles W. Goodale, of Butte is also a member of it. Both are especially interested in securing a large attendance of mining men and those interested in mining for the purpose of formulating organized action to induce Congress to revise the existing and inadequate mining laws. Many individual and unorganized efforts have been made to get Congress to do something in the nature of needed revisions of the mining laws, but Congress has paid no attention to the matter or to the petitions of mining men. It is hoped that a united effort representative of many American mining and business organizations will be effective.

The Washoe Reduction Works at Anaconda is making extensive improvements and changes in many departments of the plant. A new box-type treater for the Cottrell system of precipitating dust and fumes from smoke has been installed which is less expensive than the one heretofore in use. In the concentrator, work is progressing rapidly on the remodeling of section No. 3. The filter plant for slime concentrates is being doubled and excavations for No. 3 roaster plant are completed and ready for concrete foundation work. The leaching plant for tailings is now running full capacity of 2000 tons a day, making a much better extraction than was anticipated. Plant for the Lavoisite process of manufacturing oxygen for oxyacetylene welding, recently completed, is proving satisfactory. Product is kept in tanks ready for shipment or for use in the works. In converter building, new repair shop is being built and the foundation for No. 4 Great Falls type converter is nearly completed. In the reverberatory department a new matte track and a new repair shop for the coal-pulverizing plant are being built. Two more dryers are also being added to that plant.

SALT LAKE CITY—July 16

Discovery of Zinc and Lead on Promontory Point 30 miles west of Ogden is reported to be exciting local enthusiasts. A territory 9 miles square is said to be dotted with locations. The Lakeview company is reported to have taken out $23,000 during the last three months.

Holdings of the Grasselli Chemical Co. at Park City have been taken under lease and bond by C. C. Broadwater, of the Merrill Metallurgical Co., of San Francisco, and associates. The property consists of a concentrating plant of 125 tons daily capacity and various tailings dumps. It is understood that an effort will be made by the San Francisco company to treat some of the latter. The principal value is in zinc with some lead and silver. Details as to the method of treatment have not been announced but tests have been made and it is thought probable that a flotation process will be used. A year or two ago another Grasselli mill—a zinc dry-concentrating plant—was sold to the Park City Mills Co., and remodeled for chloridizing-leaching.

SEATTLE—July 15

Fire Destroyed the Business Section of Valdez, July 15, with a loss of $500,000. United States troops from Fort Liscum aided in checking the flames with dynamite. No rain had fallen for weeks and the wooden buildings were dry as tinder.

Nineteen Tons of Gold were deposited in the Seattle branch of the U. S. Assay office during the fiscal year of 1915 ended June 30, according to official report. The coining value, smelted and resmelted into bars, is $8,850,454, representing 2288 deposits of a total of 555,323 oz. troy. The total valuation of Alaska contributions for the fiscal year is placed at $6,313,383 from the following districts: Kuskokwim, $2534; Circle, $54,922; Cook Inlet, $378,936; Copper River, $528,691; Eagle, $40,298; Iditarod, $1,437,038; Koyukuk, $114,891; Nome, $2,744,141; Southeastern Alaska, $104,769; Tanana, $908,061. The same districts also deposited 42,211 oz. of silver. British Columbia contributed $1,492,564 in gold and the Yukon territory, $843,968 in gold. Since 1898 the Nome district has deposited in the local assay office a total of $53,932,833 and the Tanana district, $45,990,912.

Shortage of Water caused considerable trouble in the Fairbanks district during the first part of June. On Vault and Dome there was scarcely enough water to feed the boilers. Cleary, Pedro and Fairbanks Creeks also suffered. In spite of this difficulty there was great activity on most of the old producers, especially at the mouth of Cleary, where Sam Weiss, Pete Malone, Scannel & Driscoll, Herman Magnusson, McConnell, Alex. Niemer, Keys & Rettig, and several smaller plants, were sluicing.

The Experiment of Water Transportation from Fairbanks to the Tolovana is working out well. The steamer "Dan" lands freight at the log jam for 2½c. per lb. Al. Lien is building a tramway past the jam and will transfer freight to navigable water above the jam for ½c. From the upper end of the portage the power boat "Doman" takes the freight to the West Fork of the Tolovana, about 8 miles from Discovery, Livengood Creek, for 2½c. Pack-trains transport it the rest of the way for 1c. a pound, making the total cost 6½c. from Fairbanks to the diggings. Dave Cascaden, Walter Fisher, Julius Hoffman, and J. H. McCord have incorporated the Tolovana Lumber Co. and will erect a mill near the mouth of Livengood Creek.

Another Stamp Mill Is to be installed in addition to the one now in use on Fairbanks Creek. The first installation proved so successful, although entirely too small to handle even the ore that is already waiting to be crushed, that it induced Thomas Gilmore to purchase a mill site on 13 Above, first tier, left limit Fairbanks Creek and the purchase of a five-stamp mill, the only one in the district, owned by Edward McConnell who had recently purchased it to work his ground on Garden Island. Several organizations are now figuring on purchasing small mills and shipping them from the outside this winter. Five more stamps will be added to the latest mill if the new one comes up to expectations and the quartz owners of the district are jubilant over the prospects of getting the values out of their properties. The first ore to be crushed will be taken from the O'Connor & Stevens property at the head of Fairbanks Creek where there is enough ore in sight to keep the mill operating for several months. The Mizpah and other properties are also preparing to ship ore as soon as the mill is installed.

BRISTOL, TENN.—July 18

The Interest in Southwest Virginia and East Tennessee has continued to increase, although no important undertakings have been developed. The Fall Branch mine, in Sullivan County, Tenn., is under option to Frank R. Walton and associates, of Philadelphia. This property is developed and has a mill. There is a peculiar asphaltum compound associated with the ore. The Haysville iron deposits in Greene County, Tenn., have been explored for zinc and it is reported that operations to mine the zinc and iron ore will be undertaken soon. The deposit is like that at Embreeville, about 20 miles to the northeast and on the same flank of the Unaka range The old iron mines at Embreeville which have been operated for several years for zinc are now controlled by the New Jersey Zinc Co.

The Carter Property at Ivanhoe, Wythe County, Virginia has installed an adaptation of the flotation process for the separation of the sulphide ores and the results are said to be satisfactory. Pittsburgh and Ohio men have options on the Jackson and Wissler properties at Ivanhoe and have done some developing. The Austinville properties, adjoining, are operating extensively under the ownership of the New Jersey Zinc Co. At Allisonia, about five miles southwest of Pulaski, the Forney-Caldwell interests have done considerable exploration work on an extensive deposit of zinc- and iron-sulphide ore, occurring in the limestone and crossing New River. The ore runs from 10 to 20% in zinc with a little lead. The property was recently examined by Kirby Thomas, of New York, and experiments with the treatment of the ore are being made. D. S. Forney, of Pulaski, has taken a lease on the old Clark ore bank, near Allisonia, and is shipping carbonate and silicate ore.

The Faber Mine, in Albemarle County, Virginia, has been recently taken under option by Philadelphia interests and is being unwatered. This property contains zinc ore and fluorspar and it is said that the present negotiation is with the view of operating the property for the latter mineral. State Geologist, Thomas L. Watson, will shortly undertake an investigation of zinc deposits of southwest Virginia.

ISHPEMING.—July 19

Ore Shipments for 1915, it is now believed, will total close to 40,000,000 tons, which would be an increase of almost 7,000,000 tons over 1914. Up to July 1, this year, the tonnage that went down the lakes amounted to 11,521,283 tons, an increase of 1,897,167 tons over the same period last year. It is safe to predict that about 26,000,000 tons will go down the lakes during July, August and September, and from the way orders are being booked and vessels chartered there will be a fair movement during October and November. Large sales of ore have been made during the last few weeks, and many of the furnace companies that stated the early part of the season that they would not require all of the ore called for in their contracts are now demanding that everything ordered be shipped. The Oliver Iron Mining Co. is working its mines to capacity, and many of the independents are now getting into better shape and mining more ore. Mining men of the district are wondering how long it will be before ores of the bessemer grades cease to command a premium in the market. Most of the furnaces that have been constructed during recent years manufacture steel by the open-hearth process and it will probably not be long before there are few bessemer plants in existence in this country. The non-bessemer ores work just as well in the open-hearth furnaces as do the ores carrying low phosphorus content, and the opinion is now held that it will be only a few years before the bessemer grades will no longer bring higher prices in the market. The non-bessemer ores greatly predominate at the present time, there being only a few mines now that hoist much of the bessemer product. Some of the Marquette and Gogebic range mines still produce a good deal of the higher-priced ore, but the percentage of the total is small. A short time ago the Montreal Mining Co., Montreal, Wis., shipped two cars of ore, running 69%, to New York, where it will be used for checking purposes. This is as high-grade iron ore as was ever mined in the Lake Superior district. There are millions of tons of low-grade ores in the district, but the time is coming when they will all be in demand.

CUPRUM, IDA.—July 10

The Seven Devils Mining District is apparently coming into its own, due to renewed activity on account of the advance in the price of copper and the gradual disappearance of the disadvantages under which the district operated in former times. The mines of the district have shipped between 20,000 and 30,000 tons of copper ore, averaging from 10 to 40%, mostly hauled by wagons over distances of 45 to 100 miles to railroad transportation. The Peacock Mine, whose deepest working is a 150-ft. shaft, has a lens of ore, which on surface measures 100 ft. wide by 300 ft. long. The ore from this mine averages 6% copper, which of course will not stand a 100-mile wagon haul. This company is said to be under option to San Francisco people and its early resumption of operation is expected. Adjoining the Peacock on the south is the South Peacock, which is being operated by Butte men. This mine has a 300-ft. shaft and has ore of about the same grade as the Peacock, which can be sorted to make a 16% grade which would stand being hauled to the railroad at Homestead, 20 miles distant and would show a profit at the present price of copper. At the Queen mine a carload of 30% ore, extracted during the past winter, on a lease, is being shipped. There is talk of resuming work on the Decorah-Arkansas group, and work is being done on the Badger group nearby. At Deep Creek, 6 miles north of the Peacock mine and within 2 miles of Snake River, at a point 17 miles north of the railroad at Homestead, the Red Ledge mine is being developed with a small crew. Talk of railroad accommodation is again current, and the state mine inspector is quoted as follows: "To my notion the most feasible solution of a north and south railway is over the Snake River route, by extending the present branch from Homestead, Ore., via the Idaho side of the cañon to Lewiston. The distance to build would be shorter than the route already outlined further east, and it would have the advantage of a natural water grade of 8 ft. to the mile and while probably more expensive to build in initial cost, it would afford the most direct connection in a single system of control through to north Idaho."

KELLOGG, IDA.—July 14

Activity on the North Fork of Cœur d'Alene River has been stimulated by prevailing high prices for zinc and antimony. Theodore Brown and John Finnel are developing a promising 14-in. vein of stibnite in Pine Creek district on claims that were abandoned several years ago and recently relocated. A good strike of zinc ore has been made at the Terrible Edith mine, near Murray, under lease to Charles and W. H. Conn. The lessees have been shipping 50 tons of ore a month and plan to increase output to 100 tons. At the 1000-ft. station in the lower tunnel the Samson has opened an orebody for 100 ft. that contains streak of milling ore several feet wide. The Paragon is engaged in blocking out ore. Shipments were held up some time ago by trouble over smelting contracts, but it is hoped to have difficulty removed soon.

JOPLIN—July 17

Miners' Strike involving 5000 lead and zinc miners fell to pieces and work was resumed full force July 12.

The Mining News

ALASKA

NO. 3 BELOW, DOME CREEK (Fairbanks)—Frank Fisher has purchased interest of Al Rice in lay on 3 Below, Dome Creek; large dump was taken out during winter.

CHICHAGOFF MINING CO. (Chichagoff)—W. R. Rust, of Tacoma smeltery visited property recently to inspect increased and improved milling capacity, as well as new compressor installation. James Freeburn is superintendent.

SELCH, DIETZ & WALKER (Ruby)—These operators, who expected to clean up $80,000 from their winter dump, obtained $90,000 after sluicing about half of it. Alexander Larsen has found $7 ground on Long Creek and let it out on lays.

MIDWAY ASSOCIATION (Fairbanks)—Sjolseth Bros. have found good pay on this Ester Creek claim and plan to move their plant from Gold Hill at once. Owners of claim, E. A. Suter, P. C. Charles and L. B. Clough, have bonded claim to Jack Leach for $20,000, of which $1000 was paid in cash.

E. M. ALDRICH (Juneau)—Located mining and water rights at William Henry Bay on Lynn Canal. This property is practically due West of Berner's Bay and across from the Jualin property, near Comet. Property likely to be opened up in small way this summer.

RELIANCE MINING (Fairbanks)—Workmen employed on property of this company, lying at head of Dome Creek, during summer and fall of 1913 have been granted lien against property by order recently signed by Judge Bunnel in District Court. Claim owners plan to carry case to Circuit Court of Appeals. Validity of territorial lien law involved.

CACHE CREEK DREDGING (Cook Inlet)—First gold dredge to be taken into Yentna mining district is being shipped by this company for operation during next summer. Material will be held at McDougal until snow flies when it will be shipped overland to ground to be worked. It is 7-cu.ft. bucket machine with capacity of 3000 yd. per day.

BIG CHENA (Fairbanks)—Shamrock Creek, on which $1.50 ground was found last winter, has been staked from end to end and is expected to make an important production this summer. Van Curler, who has been working in the district for several years, will probably move his plant, the only one of any size available this summer, to new creek.

M. O. BARNEY (Juneau)—Attorney for H. W. Martin, of New York, has taken possession of Hallum, Dora, Salmon Creek and other properties for his client. These properties have been under supervision of George R. Noble. It is reported that R. A. Kinzie, former superintendent Alaska Treadwell, will eventually take complete charge of properties.

VALDEZ CREEK PLACER MINES (Valdez)—Are ready to enter ranks of producing companies in Valdez district, hydraulic plant having recently been completed. Development work during last year cost about $200,000 and was financed largely by Boston capital. Ground shows value of $2.70 per cu.yd. Plant will run steadily until Sept. 1 when first cleanup will be made.

ALASKA GOLD (Juneau)—President Hayden is quoted as authority for statement that in June mill treated 90,790 tons of ore. First section of mill treated 2500 tons per day until middle of month, when part of second section went into operation, when 3500 tons were handled, which has now been raised to 4000 tons, and will in a few days reach 5000 tons daily. Third section expected to start latter part of August. By end of September expected to treat 7500 tons daily. Total 10,000-ton capacity to be reached by Jan. 1. There is no intention of increasing mill beyond this capacity in near future.

AMERICAN TIN DREDGING (New Cape York)—New tin dredge has been shipped here by this company to operate on Buck Creek. New dredge is equipped with screen and double flumes so that no time will be lost in cleaning up and is third of its kind to be installed in district. Gravel on creek contains large percentage of tin ore and small percentage of gold. About 200 tons of tin ore have already been taken out from this creek and a 2-ton motor truck, the farthest-north automobile on American continent, was recently shipped in to haul ore to tidewater for shipment to tin smeltery to be built in Seattle.

ARIZONA

Maricopa County

YOUNG MINES CO. LTD. (Mesa)—Stamp mill is in operation; oil is now being used for fuel instead of coal.

ORO FINO (Phœnix)—Is taking out carload of high-grade ore for shipment to Douglas. Sinking main shaft continues. Hoist is to be installed.

CALIFORNIA

Amador County

KENNEDY (Jackson)—The 100-stamp mill is crushing good ore from the lower levels. Tailing wheels are in satisfactory operation and the dam is proving a satisfactory method of impounding the tailings.

TREASURE (Amador City)—Savo Kosich, 31 years old, an Austrian miner was killed July 7 by the explosion of a missed hole. Kosich's head was blown off. His working partner lost an arm and was otherwise injured.

MACE ASBESTOS MINING CO. (Ione)—New incorporation with capital stock at $75,000. Directors are W. C. Lilian, of Stockton, H. Herman, A. L. Harnett and John V. Powers, of Ione, and George W. Lucot, of Jackson. Company will operate asbestos deposits near Ione.

CENTRAL EUREKA (Sutter Creek)—Shaft has passed the 3260-ft. point and is being deepened. At 3300-ft. level station will be cut and drifts driven to pick up the orebody developed in the 3100 level. Probable that shaft will be deepened to 3400 ft. and new level run at that point. Forty stamps dropping.

Eldorado County

BURTON (Garden Valley)—E. G. Carlquist has purchased this mine near Sailor Flat adjoining the old St. Lawrence property. Reported that a good ledge has been disclosed since development began.

RYAN (Shingle Springs)—Property has been taken over by mining men of Manhattan, Nevada. Installation of modern machinery is contemplated, including the 100-ton ore crusher. Water will be supplied from the Oakland Terminal Power Co. ditch through 2000 ft. of 3-in. pipe. A 50-hp. gasoline engine pumping plant will be installed on the bank of the creek.

Mono County

PITTSBURG-LIBERTY (Masonic)—Initial operation of the new tube mill and cyanide plant is reported to have proved that $10 ore can be profitably mined and treated. Development of orebodies shows sufficient ore blocked out to run the mill for two years.

Nevada County

CHAMPION (Grass Valley)—Reported that $300,000 produced in the past year has been expended in mining and development. A large amount went into new machinery, buildings and the opening up of large areas of underground work.

GOLDEN CENTER (Grass Valley)—Reported that contract has been let for 110 ft. steel headframe for the vertical shaft. Shaft will be deepened to 1000 ft. Pump will be installed at that point with a capacity of 300 gal. per minute. Crosscut at 1000-ft. point contemplated to cut the Peabody vein.

Santa Clara County

J. MORENO VS. NEW GUADALUPE QUICKSILVER MINING CO. (San Jose)—Plaintiff awarded $8000 damage by Superior Court for death of husband who was killed in an ore-car accident.

Shasta County

GLADSTONE (French Gulch)—Force of 120 men employed at this gold mine; 40-stamp mill running steadily. Sinking 200-ft. winze from lowest or 1200-ft. level underway.

SPREAD EAGLE (Kennett)—Considerable lateral development being done, sinking also under way. Property seven miles west of Coram and owned by Mammoth Copper Mining Co.

UNCLE SAM (Coram)—Operations resumed at this gold mine six miles west of Coram, on Squaw Creek. Ten-stamp mill put in operation. Property has made large gold production in past.

STOWELL (Kennett)—This copper property under option to Mammoth Copper Mining Co. which is doing considerable development work upon it. New 2-compartment shaft being sunk. Fair tonnage good-grade copper ore assaying a little in gold and silver blocked out; this ore discovered by diamond drilling. Compressor installed recently.

Trinity County

ASBESTOS MILLING PLANT—Installation is reported to be contemplated at Oakland by L. V. Stevens, mining engineer with interests in California and Mexico. The purpose is to handle asbestos mined in this county.

Tuolumne County

BLACK OAK (Soulsbyville)—Thomas Ayoob, a Syrian miner, 36 years old, was found dead on July 1, in a water sump just below a loading platform at the delivery end of a chute where he had been working. Body was cut by the falling rock but direct cause of death believed to be drowning.

COLORADO

Boulder County

GOLD FARM (Magnolia)—Exploratory work done on this property last season will be resumed and systematic development will be performed under direction of Col. W. H. Moore, representing group of Lincoln, Neb., men.

BOULDER TUNGSTEN (Boulder)—Promising orebody is being developed in east heading from Forest Home shaft. This level recently broke into old workings of Cold Spring No. 2 mine of Wolf Tongue Co., which is considered encouraging in view of fact that Cold Spring vein has produced high-grade ore in past.

Lake County

WESTERN ZINC OXIDE (Leadville)—Smeltery operating full capacity treating nonsulphide zinc ores of this region.

MOUNT CHAMPION (Leadville))—Four teams are kept busy handling high-grade gold ore from mine in Half Moon gulch on Mt. Massive to railroad at Malta.

NEW MONARCH (Leadville)—Leases all doing well, several averaging carload of ore each per day. Company is developing new deeper ground.

BIG FOUR (Leadville)—Mine is again active after its long shutdown following destruction by fire of its surface plant. Is shipping steady tonnage of $20 ore.

IBEX (Leadville)—Jacketts lease ships regular tonnage of high-grade smithsonite averaging 40% zinc. Tonnage pro-

duced to these properties during June was greatest monthly production in 5 years, while average grade was also highest.

PENROSE (Leadville)—Water having been lowered below 470-ft. point in shaft, first to projected pumping stations is being excavated. Shaft pumps will merely hold water below this level until station pump is ready to operate when they will resume heavy pumping and lower water to second pump station.

Teller County

VICTOR (Altman)—Schultz, et al, ship carload lot per week. Winston lease has made its first shipment to Golden Cycle mill, Colorado City.

VOLCANO (Cripple Creek)—In 60-ft. prospect shaft on Gold Hill, leasers struck vein of highgrade ore. They are preparing to ship.

ELLA B. (Cripple Creek)—Johnson and McQuarrie, in new prospect hole on Tenderfoot hill, have struck large body of ore and have begun shipments.

GRANITE (Victor)—Stock now listed on Colorado Springs Mining Stock Exchange. Company owns Granite, Gold Coin, Monumment, Dillon and Dead Pine mines, all close to Victor.

DEAD PINE (Victor)—On 400 level, McIntosh-Ingram leasers have drifted through cave-in that occurred years ago and are reclaiming an old stope said to have produced 1.5-oz. ore.

HONDO (Victor)—Sinking of main shaft continues. Body of milling ore was struck and is being mined and dumped on surface until contemplated mill may be erected. Some shipping ore is being marketed.

GOLDEN CYCLE M. & R. CO. (Colorado Springs)—Mill treated 36,000 tons of Cripple Creek ore during June, earning profit of nearly $60,000. It is still handling Cresson high-grade ore. Company is also producing ores from its own mines.

BLUE BIRD (Altman)—E. S. Johnson, sole owner and operator of this mine until few months ago, has granted option to purchase to Nelson Franklin who has been leasing since last December. Plans are being made to erect cyanide mill at mine. Property covers only 13 acres but its vein is remarkably strong and in many places very rich. Years ago, it produced many carload shipments of ore worth several dollars per pound. The shaft is 1865 ft. deep or 450 ft. above level of Roosevelt tunnel. Several sets of sub-leasers are operating on sliding-royalty scale.

IDAHO

Shoshone County

LITTLE PITTSBURG GROUP (Murray)—This silver-lead property, owned by G. A. Smith, is attracting considerable attention. Early in June the miners tapped the vein, which they crosscut for 14 ft. without reaching the hanging wall. Drift along vein shows 14 in. of high-grade zinc ore and 6 ft. of milling ore.

SUCCESS (Wallace)—June report shows that shipments of zinc ore brought $168,803 and shipments of lead ore $12,066. Operating and other expenses totaled $37,500, leaving net balance of $143,000. Report showed $179,531 on hand, with $85,069 worth of ore stored in mill and in transit to smelters, giving total of $264,600. The output is gradually being increased to 2000 tons per month.

HANDSPIKE (Wallace)—Handspike group owned by Little North Fork Mining & Mill Co., will be put on shipping basis, according to plans of management. Property lies above Horst-Powell mine and road is now being built from Handspike to that mine to provide outlet for ore. Driving is under way in mine and considerable ore taken out during development is on dump. Nearby Hamburg-American and Riverside properties are also being actively developed.

HYPOTHEEK (Wallace)—At a meeting of stockholders July 2 and 3 it was decided to use part of funds derived from sale of bonds to develop mine. Also decided to increase capital stock from 1,500,000 shares, par value 10c., to 2,000,000 shares. Drift on 900 level has been continued through mountain and three-compartment raise has been put up to surface on east fork of French Gulch. Raise now used as main working shaft in sinking to 1100-ft. level. W. W. Davidson, president, and J. H. Kern, general manager.

MICHIGAN

Copper

ONONDAGA (Houghton)—Has one diamond drill in operation and the second will be put into service as soon as the first strikes the ledge.

ALLOUEZ (Keweenaw)—Rock shipments are increasing and will continue to be maintained at the highest point in the history of the mine.

MASS (Mass City)—Will be back to 1200 tons daily this week. For the past week or ten days the shipments have been limited to 900 tons, due to difficulties with the hoisting plant.

LAKE (Houghton)—Shipped 15 cars of copper rock from mine to the Copper Range stamp mill at Beacon hill. Shipments will not be maintained at this high point for the present as this represents an accumulation of the first few days of rock hoisting. Plan to maintain the shipments at the rate of 10 cars, 400 tons daily, for the present. In getting the Lake mine cleaned and in running condition Manager Walker has achieved quite as much of a success as he did with Mass.

CALUMET & HECLA (Calumet)—The dredge, recrushing plant, classifier and turbine that furnishes the power for their operation are all out on commission and may be for a month or longer. A cable sheave broke into a live wire which created a short circuit. This put the generator for the turbine out of commission. This turbine furnishes the power that actuates the dredge and recrushers and classifiers. There is plenty of spare power but it is not applicable to the plants in question. Officials do not now know just how much time will be required to repair the damages and get the turbine generator into commission again. In the meantime the men employed in this auxiliary to the milling plant at Lake Linden are on vacation.

MONTANA

Hill County

HAVRE NATURAL GAS CO. (Havre)—Encouraged by recent strike of natural gas in well sunk by this company near Havre, it was decided to drill several more at once. Great Northern Ry. is said to contemplate erection of shops, using gas for power, and a number of capitalists are on the ground looking to the placing of other industries.

Silver Bow County

ANACONDA COPPER MINING CO. (Butte)—In spite of accident to concentrator of Washoe plant at Anaconda, which caused temporary curtailment in output in the latter part of June, the output for that month exceeded that of any month since last summer and was close to output for June a year ago. 22,300,000 lb. copper produced.

PARROT MINING CO. (Butte)—Work has begun on the removal of the steel headframe of the Parrot mine to the Never Sweat, where it will replace the old timber frame. The Parrot shaft was abandoned long ago as an operating shaft when mine was taken over by the Anaconda and exploited through the adjoining mines of that company. The removal of the frame marks final disappearance of evidences of activity at one of the famous Butte mines which was discovered in 1864 and became famous as a producer of exceedingly rich silver ore. The Parrot was taken over by the Amalgamated company in 1900.

NEVADA

Esmeralda County

JUMBO EXTENSION (Goldfield)—With exception of few days at beginning of month, daily shipments for June averaged 100 tons per day.

GOLDFIELD CONSOLIDATED (Goldfield)—Final official figures for May show production was 32,380 tons of ore from which $161,653 was realized.

ROUND MT. SPHINX (Round Mountain)—After legal battle lasting several years, Sphinx company, about year ago, adjusted its apex controversy with Round Mt. Mining Co. by turning over property to latter and receiving therefore cash and stock, which are now being liquidated to stockholders. Corporation will then be dissolved.

NEW GOLDFIELD SIMMERONE (Goldfield)—A round into what has been regarded footwall, after passing through seam of hard material, exposed 18 in. of ore which averages from $50 to $100 per ton. This is within 2½ ft. of old workings from which high-grade ore was extracted in early days of Goldfield.

Nye County

TONOPAH ORE PRODUCTION for week ended July 10 amounted to 8264 tons valued at $174,712 compared with 10,100 tons week previous. Decrease due to 4th of July holiday. Producers were: Tonopah Belmont, 2458; Tonopah Mining, 2400; Tonopah Extension, 1580; West End, 864; Jim Butler, 850; and miscellaneous leasers 112 tons.

TONOPAH-BELMONT (Tonopah)—H. P. Henderson, mining engineer, has been sent by Belmont company to make examination of Potosi mine, and he and his assistants recently arrived in Nicaragua. Steady progress being made at both Surprise and Hart properties, but no information is at hand as to the results obtained recently.

Storey County

MEXICAN (Virginia City)—Mill crushed 140 tons of ore, assaying $11.09 per ton.

UNION CONSOLIDATED (Virginia City)—At 275-ft. point in north drift 2500 level, 5 to 7 ft. of quartz assayed $4 to $14 per ton.

SIERRA NEVADA AND UNION (Virginia City)—West crosscut on 2500 level opened to 274-ft. point in Comstock country.

COMSTOCK PUMPING ASSOCIATION (Virginia City)—Flumes and dam installed on 2700 level to divert water to Ophir-Mexican winze pumps.

JACKET-CROWN POINT-BELCHER (Gold Hill)—Mill received 1090 tons dump rock and 280 tons mine rock. One bar bullion shipped to smeltery.

OPHIR (Virginia City)—At central tunnel development was started on 6-ft. streak of quartz in parallel drift nearer the foot wall. Saved 232 cars of ore, and milled 175 tons.

OPHIR AND CONSOLIDATED VIRGINIA (Virginia City)—The 210-ft. level has been reached in reopening the east crosscut on the 2500 level boundary line, leading to the 2700 winze.

NEW MEXICO

Grant County

LESSEES IN THE TYRONE DISTRICT are taking out encouraging lots of copper ore. Dumps are being worked and many prospects are being developed. Shipments are being made over El Paso & Southwestern siding.

WORK ON THE SPUR connecting the Arizona & New Mexico Railway with the 85 Mine and other properties in the Virginia mining district, was begun July 13 by the A. & N. M. R.R. Co. No contracts were let. Company employing about 400 men on grading. Spur is expected to be in operation by Sept. 1.

SOUTHWESTERN NEW MEXICO MINES CO. (Hachita)—Has filed articles of incorporation. Will operate mines near Hachita.

MODOC (Fierro)—Mine under operation by J. W. Bible from Brockman estate. Shipments averaging a car-load daily. High in copper and iron.

WALDO (Lordsburg)—The Waldo lead concentrator will begin operations about July 18. Machinery in place and everything in readiness.

EMPIRE ZINC CO. (Hanover)—Grading to soon begin for a new powerhouse here. Lateral work under way on Thunderbolt mine. Carbonate shipments from Nason tunnel continue regularly.

CHINO (Santa Rita)—Company has increased wages of employees 10%, as long as selling price of copper is at 17c. or above. Notices to employees state: "This new scale is put into effect in appreciation of the friendly assistance of our employees in the past, and with a desire that they may share in the increased prosperity which has come so unexpectedly. No one can anticipate how long the present condition in the copper market may continue, but you can be assured that these rates will not be changed for every fluctuation that may occur below the price named."

Santa Fe County

SANTA FE GOLD & COPPER CO. (San Pedro)—It is understood that earnings in June were slightly over $20,000. Company has under consideration the erection of plant equipped with flotation machinery for treatment of its low-grade ores.

Socorro County

ERNESTINE (Mogollon)—Has declared first dividend in two years. Present dividend 2%, aggregating $50,000. Development work interrupted dividend payments.

MOGOLLON GOLD & COPPER CO. (Mogollon)—Property will be sold at Socorro, N. M., July 26 to satisfy judgment for $416,626 given the Equitable Trust Co., of New York. Milton J. Helmick, Socorro, N. M., trustee.

NEW YORK

St. Lawrence County

NORTHERN ORE CO. (Edwards)—This zinc company of Pilling & Crane, is speeding up production at its new mill recently erected to replace former mill destroyed by fire. Justice Grugan is manager. Another zinc property several miles from Edwards is being developed by A. J. Moore who preceded Mr. Grugan as manager for Northern Ore Co.

ALUMINUM CO. OF AMERICA (Massena)—The Massena plant of this company near the St. Lawrence River has been undergoing extensive additions. Large force of men employed on new work has boomed village of Massena. Electrical current, necessary in large quantity for reduction purposes is obtained from power installations on tributaries to St. Lawrence River.

UNIFORM FIBROUS TALC CO. (Taleville)—This company and St. Lawrence Talc Co., of Natural Bridge have materially increased their grinding capacity by addition of more cylinders and operating companies. International Pulp Co. and Ontario Talc Co. continue their usual productions. Operating power from Oswegatchie River which determines summer work has been good due to recent rains.

PENNSYLVANIA

Delaware County

BENZOL PRODUCTS CO. (Marcus Hook)—Plant now under construction expected to be completed within month or two. Product of plant said to be intended mostly for aniline dyes, on which problem General Chemical Co. is working in connection with American Coal Products Co. and Semet-Solvay Co.

Northampton County

LEHIGH COKE CO. (So. Bethlehem)—Contract has been let for new benzol plant to manufacture benzol from gas from present coke ovens, which treat 3000 tons of coal per day. Installation will be so laid out that it can be readily duplicated to handle gas from 212 additional ovens now under construction. Production of benzol expected to begin in less than four months.

SOUTH DAKOTA

Lawrence County

WASP NO. 2 (Flatiron)—Plant operating full capacity of 500 tons. Shipments of high-grade tungsten ore being made.

RATTLE SNAKE JACK (Galena)—Mill nearly completed and will be put into operation during present month. Trent system of cyanidation installed. Plant will treat 50 tons daily.

GOLDEN REWARD (Terry)—Roaster at Astoria mine will be put into commission about middle of month and kept in continuous operation. Mill at present is operating at capacity on oxidized ores from Bald Mountain mines.

HOMESTAKE EXTENSION (Deadwood)—Engineers are unwatering property, preparatory to thorough sampling of mine. Expected that this work will take several months. Jackhamer drills will be used to facilitate work.

NORTH HOMESTAKE (Maitland)—Shaft has been unwatered below 400 level by means of skips. It is expected that within week entire mine will be unwatered. Machinery is being put into shape and work will commence soon.

HOMESTAKE (Lead)—Company will enter first-aid team in contests at San Francisco Fair this fall. Work has been resumed on 1850 level of mine and it is probable that sinking will be commenced as soon as this level is opened up for active work. New boiler plant is nearing completion, one of 210-ft. smokestacks has been set up and work on second has commenced.

TEXAS

Potter County

WILL A. MILLER AND ASSOCIATES are promoting development of potash deposits near Amarillo. It is planned to install machinery and equipment for extracting mineral product from deep wells.

UTAH

Salt Lake County

COLUMBUS EXTENSION (Alta)—Drifting to southwest is being done under old Toledo fissure. Henry Barney is new superintendent.

ALTA CONSOLIDATED (Alta)—Development work is progressing more rapidly, since installation of machine drills. Six inches of ore has been opened in No. 2 drift, east from main tunnel.

WASATCH-UTAH (Salt Lake)—This company, which has installed Koering mill and is cyaniding low-grade gold-silver ore, is reported to be making good extraction. Property is at mouth of Little Cottonwood.

SELLS (Alta)—From three to eight inches of sulphide ore has been opened on quartzite-limestone contact, along which 110 ft. of drifting has been done. Objective point is intersection with Skipper fissure, which carries ore in shallow surface workings. Operations are being carried on through main South Hecla tunnel.

CARDIFF (Salt Lake)—Recent visitors to this property report orebody to be opening up larger than ever, with extent undetermined. It has been opened 250 ft. on strike; and crosscuts show width up to 100 ft. On dip ore has been followed for more than 200 ft. above tunnel by raising, while winze has been sunk 90 ft. in ore below it. Shipments of about 90 tons daily are being made, these being limited by number of ore wagons obtainable. Hauling costs about $1 per ton.

Summit County

SILVER KING COALITION (Park City)—Work on new flotation section is in progress. Capacity will be 60 tons per eight-hour shift.

THREE KINGS (Park City)—Shaft sinking continues at this property in Nigger Hollow, with depth of 500 ft. to be attained. W. M. O'Brien has sold out to his associates.

Tooele County

SIMMS GROUP (Gandy)—These claims in Deep Creek district, on which tungsten ore has been opened are reported sold to Colorado company. Mill may be built.

Utah County

CONSIDERABLE ACTIVITY IN AMERICAN FORK CAÑON at present. Camp is attracting outside attention. Roads are in good shape for more than 20 miles.

MILLER HILL (American Fork)—First car of ore to be brought down cañon since melting of snow has been shipped by Wadley lease on this property.

BELLEROPHON (American Fork)—Strike of silver-lead ore has been made in tunnel on Live Yankee claim. Road will be put in condition for shipping.

MINERAL FLAT (American Fork)—Ore hauling has been started from this property, operated under lease. Several cars running well in lead and silver, with some gold, are ready for shipment.

ETTA MAY (American Fork)—Work has been started on vein, which appears promising at outcrop. Property was recently inspected by Salt Lake mining men. George Paramore is general manager.

CANADA

Ontario

ORE SHIPMENTS OVER THE T. & N. O. RY. for month of June were from Cobalt Proper: Beaver, 36 tons; Chambers Ferland, 52; Cobalt Comet, 76; Coniagas, 108, Crown Reserve, 118; Kerr Lake, 98; La Rose, 150; McKinley-Darragh, 247; Mining Corp of Canada, Ltd. Cobalt Lake Mine, 84.68; Townsite City, 283.98; O'Brien, 56; Penn Canadian, 143; Peterson Lake—Seneca Superior ore, 62; Temiskaming, 106. From New Liskeard: Casey Cobalt, 32. From Elk Lake: Miller Lake O'Brien, 25; total silver ore shipments, 1665 tons. From Porquis Junction: Alexo Mine (Nickel), 989 tons.

TECK-HUGHES (Kirkland Lake)—Mine has been unwatered and is being re-sampled in view of prospective sale.

POWERFUL (Calcite Lake, near Gowganda)—Operation on this property, which have been suspended for about year, have been resumed.

GIBSON CLAIMS (Goodfish Lake)—In sump below 100 level two more streaks of high-grade ore have been cut. One vein has full 12 in. of ore.

HOLLINGER RESERVE (Porcupine)—Dominion Reduction Co., is now engaged in sampling this property, to decide whether they will take up or drop option.

LAKE SHORE (Kirkland Lake)—Main vein has been cut with diamond drill 100 ft. from shaft on 100-ft. level. Sludge from drill hole averaged $48 per ton for width of 3 ft.

BEAVER CONSTRUCTION (Cobalt)—Is increasing capacity of concentrating mill to 150 tons per day. New installation to be completed in six weeks. Company has 259,480 oz. bullion in storage in New York.

HAITI

HAITIAN MINING CONCESSION—A concession just granted by the Haitian Government to the local representative of a British company carries with it the right to prospect for minerals of all kinds within that island Republic. The indemnities to be paid the owners of the land prospected over and the obligations which the company incurs are set out in full in the text of the concession.

NICARAGUA

RAILWAY CONCESSION FOR MINING DISTRICT—The Republic of Nicaragua has made a contract with the Tunky Transportation & Power Co. for the construction of a railway, and of a plant or plants for the manufacture and transmission of power, in the mining district of Pis Pis. The contract has been approved by both branches of the National Congress and duly signed by President Diaz. The National Congress gave a great deal of attention to the provisions of the contract, which appears equable to all parties concerned and it is expected to operate to the advantage of Nicaragua.

AFRICA

Transvaal

GOLD PRODUCTION IN JUNE was 755,280 oz., which is 8268 oz. less than in May, but 37,354 oz. more than in June, 1914. For the six months ended June 30 the total production was 4,086,847 oz. in 1914, and 4,408,048 oz. in 1915; an increase of 321,201 oz., or 7.9%, this year.

The Market Report

Metal Markets

NEW YORK—July 21

The prices for all of the principal metals exhibited drooping tendencies during the last week. The recessions in the prices for copper and spelter were rather sharp owing to the efforts of the producers to find a basis on which they could sell liberally.

Copper, Tin, Lead and Zinc

Copper—This market, which had been dull and reactionary for fully a month, declined rather sharply during the last week. Previously the market had been to a considerable extent in the hands of traders and dealers, the producers (who had generally sold well ahead) being content to stand aloof. Certain of the larger producers continue to maintain that position, but lately some of the smaller producers have been manifesting a desire to sell copper, and in order to do so they cut prices sharply last week. Sales were made to domestic manufacturers. There was relatively little business done for export, the London market having passed temporarily into the hands of the Japanese and Australian producers of electrolytic, who were willing to sell on lower terms than the American producers were disposed to accept. Business in Japanese electrolytic was reported done at £88, equivalent to about 18.60c. At the close there were sellers in the New York market at 18⅞@19c., regular terms, for domestic business, and at 18.70@18.75, New York, for export.

Although it is considered likely that copper may experience a further decline, there is no pessimism in evidence among the producers, and a turn of the tide is expected shortly. Domestic manufacturers are believed to be not very well covered, while the settlement of the strikes at Bridgeport and in Wales are favorable factors. Even more important as an index is the increasingly strong position of the iron and steel industry, which is regarded as marking a revival in domestic business generally. Another important factor is the probability that the British Government will within a few days make an arrangement for the release of standard copper to foreign refiners, with suitable guarantees, of course, including the assurance that raw copper taken out of England will be replaced by an equivalent quantity of electrolytic. An arrangement of this sort will tend immediately to bring standard copper back to the normal parity with refined, and will remove the bad sentimental effect that the relatively low price for standard has had in distant and uninformed quarters.

Copper Sheets have brought 25@26c. per lb. The principal manufacturer makes no base quotations. Wire is quoted at 21½@22c. per lb. at mill.

Tin—The price declined owing to dull demand and anticipation of bad effects of the strike of coal miners in Wales. Following the receipt of news of the settlement of that strike, the market rallied.

Arrivals of tin and tin concentrates at Liverpool in June, reduced to their equivalents in metallic tin, were: Bolivia, 2085; Nigeria, 225, South Africa, 28; total, 2348 long tons.

Lead—But relatively little business in this metal was reported. Some extraordinary features in the quotations are explained by the narrowness of the market. Producers generally adhere to the price of the A. S. & R. Co. and report the realization of it. On the other hand, lead has been obtained from dealers and traders at much lower figures. If somebody wanted to buy lead he was apt to have to pay the producer's price, while, if somebody wanted to sell, he was apt to have to accept a considerably lower price. It will be remarked that the St. Louis market has not gone off to the same extent as the New York market.

Spelter—There was a steady decline right through the week on relatively small business. About all of the producers were sellers, and some of them appeared to be rather urgent. The trouble with the market was that there were not enough buyers. Certain consumers made liberal offers of prompt spelter for resale and put considerable pressure on the market. There appears to be an increased supply of spelter available, both for the earlier and the later months.

According to a U. S. Consular report another zinc smeltery is to be erected in Japan to use ore to reduce Siberian ore, which previous to the war was exported to Germany.

Zinc Sheets are strong, base price $27 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras charged. The demand is steady and business is good.

Other Metals

NEW YORK—July 21

Aluminum—The market continues firm, with good demand. Prices are unchanged at 32@33c. per lb. for No. 1 ingots, New York.

The latest London quotation is £140@150 per long ton—average, 31.5c. per lb.—for No. 1 ingots.

Antimony—The market has been rather quiet, with trading limited to actual necessities. There is no material change in prices. Chinese and other ordinary brands bring 37½@40c. per lb. The special brands are nominal, 50@52½c. per lb. being asked for Cooksons.

DAILY PRICES OF METALS IN NEW YORK

			Copper	Tin	Lead		Zinc

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, easb, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York, 17c.; St. Louis-Chicago, 6 3c.; St. Louis-Pittsburgh, 13 1c.

LONDON

		Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
July	Silver	Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts. per Lb.
15	22 9/16	76⅜	77¼	92½	19 70	170	163¼	25 1/16	5 35	100	21 73

20	22 9/16	74½	76	90½	19.27	164½	160½	24¼	5.29	96	20 46
21	22 9/16	75¼	77⅛	90½	19.27	165⅜	161¼	24 11/16	5.26	96	20 46

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Nickel is steady and unchanged at 40@45c. per lb. for ordinary forms, according to size of order. Electrolytic 3c. per lb. higher.

Quicksilver is strong and in good demand, with prices well held and showing little change. New York price is $92@94 per flask of 75 lb. for large orders. For smaller lots $95@100 is paid. San Francisco quotations are reported by telegraph at $92.50@95 per flask, on a quiet market. London prices is £18 5s. per flask, with £18 2s. 6d. quoted by jobbers.

Gold, Silver and Platinum

NEW YORK—July 21

Gold—No important arrivals of gold are reported during the week. Sterling Exchange continues at a low level, with a tendency to lower points yet.

Platinum—The market continues quiet, but with some gain in demand, and no material change in prices can be reported. Dealers name $37@39 per oz. for refined platinum and $41@44 per oz. for hard metal.

Our Russian correspondent writes under date of June 27 the market and the prices are without change. In Petrograd for the last fortnight no transactions have taken place. Government permission to export the platinum can be secured on condition that security will be given that the metal will not be diverted to Germany. The quotations are: at Ekaterinburg, 8.20@8.30 rubles per zolotnik; in Petrograd, 33,000 rubles per pood—equal to $31.02 and $32.34 per oz., respectively, for crude metal, 83% platinum.

Silver—The market has been pegged at 22⅞d. for several days. The latest advices are that the Indian bazaars have not been active buyers and the daily transactions are limited. In the judgment of many holders of silver the price is too low and selling at current rates is not insistent.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—July 17

The base price paid this week for 60% zinc ore was $110@115 per ton. The base price paid for 80% lead ore was $70 per ton.

SHIPMENTS WEEK ENDED JULY 17

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,067,290	124,990	500,900
Year	102,040,720	3,993,460	14,762,170

Shipped during week to separating plants, 5,365,690 lbs. zinc ore.

JOPLIN, MO.—July 17

Blende, high price $123; base per ton of 60% zinc, premium ore $120@115; medium $105@95; and for low down to $70. Calamine base per ton of 40% zinc, $52@60; average price, all grades of zinc, $102.20 per ton. Lead, high price $61; base $60 per ton of 80% metal content; average all grades of lead $57.67 per ton.

SHIPMENTS WEEK ENDED JULY 17

	Blende	Calamine	Lead	Values
Totals this week..	6,939,860	941,310	1,106,520	$435,670
Totals this year...	310,910,260	27,085,390	47,208,190	$13,102,940

Blende value, the week, $376,630; 29 weeks, $11,282,610.

Calamine value, the week, $27,160; 29 weeks, $577,470.

Lead value, the week, $31,880; 29 weeks, $1,242,860.

The strikers all returned to work Monday and the strike leader has left the district, asserting he was going to Wisconsin to run a mine. Mine owners expect to compute a wage scale based on the average assay base price per month, the wages of the succeeding month to be governed thereby. It is intended to make it just to miner and mine owner alike. The first and only strike this district ever experienced ended as it begun peacably, and while the men will maintain a union it will be for their advancement along reasonable lines.

Iron Trade Review

NEW YORK—July 21

The expansion of the steel trade continues and steel makers are beginning to look forward with confidence to an active and prosperous second half.

June pig iron output in Alabama was 122,309 tons of foundry and 36,451 of basic, a total of 158,760. The June output was the largest of the year by 12,000 tons and that of July will show as great a gain, it is expected.

The Russian order for rails, recently referred to, was divided, 100,000 tons going to the Cambria Steel Co., while the Lackawanna Steel Co. took the remaining 60,000 tons.

PITTSBURGH—July 20.

Very nearly 90% of the steel productive capacity of the United States is now in operation, this including practically all the openhearth capacity and 70 to 75% of the bessemer, production of bessemer steel having been augmented by the starting yesterday of the Riverside plant, in the Wheeling district, of the National Tube Co. One of the Riverside blast furnaces was blown in last week, while the other goes in today, putting all the 11 stacks of the Tube company in blast. The Riverside plant was started chiefly to furnish billets and skelp, the latter for export, and will make only a limited tonnage of tubular goods, the demand for which is below normal on account of the lack of oil development work.

The demand for finished steel has been augmented in the past two or three weeks by the fact that in many steel products the mills are unable to make the almost instant shipment that characterizes dull periods, thus causing buyers to attempt to lay in stocks, which have been at record low levels. This buying gives such an impetus to demand that the future of the steel market will take care of itself, and full mill operations, with advancing prices, are regarded as certain, the only question being whether the movement will cover a period of months or of years.

The entire export business in iron and steel, direct and indirect, and including war material, probably amounts now to nearly 25% of the total production, but it certainly falls far short of accounting for all the improvement the steel trade has experienced in the past seven months.

Pig Iron—Offerings of Lake front iron in the general Valley-Pittsburgh territory appear to have been discontinued, and the Valley furnaces are firm at $14 for bessemer, $13 for basic, $12.75@13 for malleable, $12.75 for No. 2 foundry and $12.50 for gray forge, while the Pittsburgh market is quotable at 95c. higher. The Republic Iron & Steel Co. has bought 20,000 tons of bessemer at $14, Valley furnaces, for delivery in the next three or four months. The whole pig iron situation is greatly improved.

Ferromanganese—The market seems rather quiet and steel makers appear less disturbed about the future than might be supposed, considering the light supplies of manganese ore reaching England and the United States. The market remains at $100, Baltimore, on contract, and $100@105 on small spot lots.

Steel—Openhearth steel has become very scarce, with prices advancing sharply. Subsidiaries of the Steel Corporation are believed to have bought in the past three weeks about 150,000 tons of openhearth billets and sheet bars, cleaning up all the offerings at former prices. We quote prices $1 a ton higher than a week ago: Bessemer billets, $21; bessemer sheet bars, $21.50; openhearth billets, $22; openhearth sheet bars, $22.50, f.o.b. maker's mill, Youngstown, and $1 higher delivered Pittsburgh. Rods are $25.50@26, with light offerings.

IRON ORE

Of the ore shipped from the Lake Superior district in June 4,941,672 tons, or 82% of the total, were for Lake Erie ports.

New York and New Jersey ores are reported to have been sold to eastern Pennsylvania furnaces at prices which work out from 6¾ to 7c. per unit, delivered.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 340,742 short tons; shipments, 330,073 tons. Production in the Greensburg and Upper Connellsville districts, 39,086 tons.

Austrian Coal Production three months ended Mar. 31, in metric tons:

	1913	1914	Changes	
Coal	4,248,164	4,021,354	D.	226,810
Brown coal	4,582,203	3,702,631	D.	879,372
Coke made	641,383	441,335	D.	200,048
Briquettes made	109,497	123,788	I.	14,291

Of the briquettes reported this year 66,405 tons were made from brown coal or lignite.

Chemicals

NEW YORK—July 21

The general market remains quiet and is still rather uneven. The present tendency of business is to improvement.

Arsenic—Business remains about as usual, with moderate demand. Prices are unchanged at about $4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is steady and shows little change. Prices are about the same at $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller parcels.

Nitrate of Soda—The market is steady, with a good demand and prices are unchanged. Quotations are 2.35c. per lb. for spot, and for all positions this year.

Pyrites—Imports at Baltimore for the week included 6482 tons pyrites from Huelva, Spain.

Stock Quotations

Only a few of the mining stocks moved upward last week; among these were Mason Valley, Nevada-Douglas, Lake, Tamarack, Timiskaming & Hudson Bay and Dome Mines. A number of the Tonopahs declined slightly, as did also Alaska Gold, Juneau, Hollinger, Caledonia, Majestic, American Zinc and Granby Consolidated.

The Engineering and Mining Journal

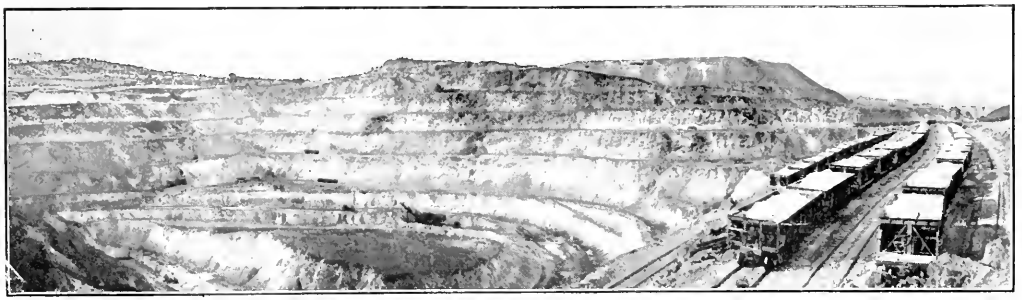
VOLUME 100 JULY 31, 1915 NUMBER 5

Essentials of Organization and Management

By J. R. Finlay*

SYNOPSIS—The methods and objects of mine management are so often misunderstood that a broad discussion is necessary. Mining is a business having clearly defined objects, among the most important of which are securing greatest ultimate profit and providing greatest present value of the property. Costs are interesting only in their relation to the whole; not as independent items.

I should like to put this discussion on broad grounds. Technical men are sometimes led into the superficial view that organization means only a list of positions to be filled; others sometimes have the idea that success in mining is not due to good management but to luck. That luck does play a good part in distributing the prizes of the mining business is undeniable, but it should be plain that it has no more to do with the proper administration of a mine than with the proper administration of anything else.



PART OF EUREKA PIT OF NEVADA CONSOLIDATED COPPER CO., ELY, NEV.

Efficiency Is Independent of Personalities

The question of efficiency in operating is quite distinct from the question of who is to be benefitted by that efficiency. We must begin by making it plain that the efficient management of a property as understood in this article relates only to getting out and disposing of the products with as little effort as possible. The emoluments that come from doing this may be so distributed as to leave many of the persons interested highly discontended, feeling that somebody is getting too much or too little of the proceeds of the industry, even though the work itself may be going on in the best possible manner. On the other hand, some individual may make a great personal gain out of a badly managed business.

Industrial efficiency means securing the maximum result from each effort and the elimination of unnecessary effort. Further, it means hitting the mark—making the organization do what it is designed to do—no more, because that costs too much; no less, because that would be a failure.

The mark to be hit by the business organization is profit. In a technical sense it is easy to conceive of an organization being highly developed to do something for which there is no commercial demand. I suppose mere scientific effort, however well directed—as, for instance, the effort of an astronomical observatory to find new stars—can hardly be called business. A mine is a purely business concern carried on with the sole object of making money. The best management—good morals and fair dealing being taken for granted—is the one that will make the most money for the stockholders.

The fire of efficiency is fanned by competition, but the management of many mining concerns is protected from competition by the nature of the enterprise. The deposit may be rich enough to pay whether it is properly worked or not, and when the profits are good the management is usually conceded to be good. This is a handicap to the managers of such properties. The proof of this is that the leading spirits of great mining concerns have usually been trained not in the management of rich mines but in the highly competitive smelting or manufacturing fields connected with mining.

*Mining engineer, 52 William St., New York.

The mining [illegible] comprises the following elements:

1. The determination of how big a field there is for the enterprise. This means usually how much ore can be counted on and how long it will take to get it out advantageously and market it.

2. How to do this work.

3. How to finance and promote the work.

These elements could be elaborated into an infinity of detail, but for the present purposes it seems best to state them this way merely to define the broad requirements which underlie the organization of mining enterprises. With this object in view let us dwell a little upon these elements.

The determination of the scope of an enterprise proceeds from information. This information comes broadly into three groups—(1) the local facts about the occurrence and development of the ore, the area of property available, the climate, facilities for transportation, labor, supplies, politics, etc.; (2) the geological situation; (3) the commercial situation—that is, knowledge of markets for the products to be dealt with.

Part of this information can and should be exact, namely, the first group. The second and third groups of information yield conclusions in the form of intelligent guesses or approximations. No one should conclude that because geological and commercial conclusions have an element of guesswork that they are therefore unimportant. Quite the contrary. For the very reason that it is impossible to see accurately through the ground or into the future it is all the more important to draw sane inferences from ascertained geological facts and from the facts of the commercial past. Just as the statesman and lawgiver would be a dangerous man if he did not know the history of nations and laws; just as the doctor would be a quack if he did not know the history of cases; so the promoter of a mining enterprise is a dangerous man if he is not acquainted with the history of mines.

It is very seldom indeed that the true measure of a mine's possibilities can be taken from the ore actually developed at the time the enterprise is launched. The development work generally keeps ahead of the extraction of ore only by a little more than the necessary margin of preparation. This fact is less sweepingly true now than it was a decade ago, and less true of low-grade deposits than of richer ones, for great progress has been made in testing mineralized areas and also in using good geology as an aid in the work of exploration. But it is unquestionable that the exploration of deposits to insure supplies of ore is in itself an important part of the conduct of the enterprise, and the wisdom of such exploration must be based upon geological inference.

Details of Operation and Finance

The actual work of mining involves all sorts of engineering—civil, mechanical, electrical, chemical, and metallurgical; the employment and discipline of labor; sanitation; transportation and the keeping of records. But the scale on which all this is to be done and the steps to be taken must be based upon the interpretation of the information already referred to. This is just as true whether the enterprise grows insensibly from a small beginning or whether it is launched suddenly as a great enterprise.

It is essential that the finances be accurately coördinated with the scale of operations. Too much money employed as capital means wasted power, the unnecessary use of resources. Too little capital means deficient operating power and may cause great losses through sheer failure to accomplish the required result. For instance, a capital limited to $1,000,000 used to start the Utah Copper Co. would have been all wasted, because the amount required to make that vast low-grade deposit pay was at least $5,000,000.

As in the case of operating, already discussed, it makes no difference in the importance of finance whether a concern grows gradually or suddenly, or whether it is owned by an individual or by a corporation, or whether it is large or small. Business involves the use of money whether that money is diverted from earnings, whether it is borrowed, or whether it is obtained from popular subscription. The financial guidance of an enterprise is just as important as its technical guidance; in fact, it underlies and empowers the technical guidance.

Futility of Unbalanced Efficiency

I have discussed the fundamental and more or less self-evident factors in order to illustrate what fields of accomplishment and training must be covered by the personnel of a mine organization, and also, if possible, to prevent persons interested in one department of the business getting a wrong idea of the importance of the other departments of it. I feel that it is so important to get these things right that it is worth while to risk repetition in laying stress on the axioms that knowledge of the physical characteristics of mines and markets will fail to reach its maximum usefulness unless it is backed up by the proper technical and operating equipment and efficiency; that, on the other hand, the technical scheme, however capable in itself, cannot deliver the proper results unless it is gaged to meet the true capabilities of the mine and its markets; and further, that commercial efficiency is out of the question unless the scheme is in tune with good finance.

The first requirement of a mine organization is that these facts shall be recognized by the owners. The basic element of efficient management therefore is efficient ownership. A substitute for ownership may be an efficient control of the stock. But after all, what security is there that the control of a corporation will stay in good hands unless the stockholders know how to see that it does?

I am inclined to think that the importance of good ownership is often overlooked by technical men and employees. It certainly is wasted effort to repair the superstructure when the foundation has given way. The secret of many a good enterprise going to seed lies in the deterioration of ownership. This is a fact that is thoroughly recognized by successful business men, whose first inquiry about an enterprise is not, "What is the property?" but, "Who are the people?"

It is of course out of the question to expect that every stockholder of a large corporation will be a good mining man, or even a good business man; but the average stockholder must know enough to put in control of the stock and of the board of directors a man, or group of men, who have the following qualifications: Honesty; sense to recognize good information about mines; good financial judgment; sense to recognize good technical, executive and commercial ability.

Assuming that an enterprise is conducted by a corporation, the cornerstone of actual management is a board of directors. While in the long run most of the work of a board is in a sense perfunctory, being habitually the indorsement of its officers, there can be no assurance whatever of good management unless it possesses the four qualifications just mentioned. A good board will probably depend on certain members to guide its judgment in certain special fields. The directors in general must be good business men; some members should be trained mining men, some trained technical men, and some trained financiers. This is the makeup of most of the boards of efficient and successful mining corporations. The more aggressive and successful a mining company is, the more decidedly has its board this kind of membership.

The idea that directors should be figureheads, if necessary, so long as they represent a certain amount of stock, generally means decadent management. A director is not necessarily a rich man. In strong concerns they are quite often distinguished employees, who contribute practical contact with the business and the interest that comes from the necessity of accomplishment. The idea that directorships should be mainly well-known names borrowed from famous financial institutions or be of social or official prominence arises generally from some need for advertisement, a need that should create suspicion.

The chief responsibility actually administered by the directors is that of finance. To them belongs the function of declaring dividends, or of authorizing loans. In this relation the importance of having a board which contains enough "mining men" to be fully alive to the peculiarities of mining is emphasized. The board must be able to understand the importance of changes shown in the development of the mines, to appreciate the need of caution when the signs point toward exhaustion, to gage the opportunities arising from favorable developments, to meet the requirements resulting from changes in the conditions of the mines, in the character of the ores and in metallurgical practice.

Duties of a President

I have been discussing the qualifications of the owners and their representatives in groups. The stockholders of mining concerns are usually many hundreds, sometimes many thousands, in number. The directors usually number from five to twenty-five. From now on I will consider individuals. Of these the most important is the president, who is the executive officer of the board. He is the central figure of the whole organization and represents both owners and employees. On the one hand, it is the president's business to exert upon the employees the authority and purposes of the owners; on the other hand, being generally an employee himself, he is bound to have to some extent the employees' point of view.

It is clear that the president's main function is to deal with people. In the case of large concerns where he must deal with thousands of stockholders and employees the job requires a decided faculty of leadership, which means insight into human nature, poise, calmness, energy and definite purpose. Technical qualifications fall into the background. Mining on a large scale approaches very closely other forms of business. The president of a large railroad system does not have to go into technical questions, but merely to deal with men who do. He forms his judgment not so much on what he knows of railroading as what he knows about men. A man who makes a success of railroading in this way could almost certainly run an equally large mining business acceptably.

The president's contact with the technical work increases as the scale of the business diminishes. In a small mine this office may become merely nominal. The president of a mining company employing only 50 men might very properly spend part of his time working underground as a miner. The division of labor is in proportion to the number employed in a given organization, and as this number diminishes, more and more functions are merged in the individual. This applies to workmen as well as officers. Just as the president of a small mining company may have to be financier, bookkeeper, manager, superintendent and foreman of his company, so the miner, who never sees the blacksmith-shop of a large property, may have to sharpen his drills as well as use them when he works in a small mine.

To create the greatest possible present value is the proper object of conducting the business. This is a point of view not easy to grasp fully or to reach, or adhere to. An abnormal exibition of low costs and large profits may be, and often is, made simply by suspending temporarily expenditures which must go on. It is also possible to take out, for a limited period, richer ore and more ore than a mine can average. So long as temporary profits are made abnormal only in the effort to obtain profits quickly, a proper object is gained by giving the stockholders the use of their profits sooner. But these temporary showings are often injurious to the property in both a physical and economic sense. Premature extraction of ores without adequate development is highly injurious by creating unnecessary dangers to men and losses of ore. Such premature mining often shows profits in such a manner as to produce a false impression of value.

Field of Technical Management

The responsibility for adhering to a broad scheme for obtaining the best results lies not with the technical management but with the president.

Among mining enterprises there is a great diversity of opinion as to what constitutes the main problem. Sometimes it is the maintenance of the ore supply by constant exploration; sometimes it is merely to secure low costs in the handling of large tonnages already assured; sometimes it is a struggle with metallurgical difficulties. But one general fact underlies practically all operations, namely, that results are obtained not through muscular activities of men, but by the intelligent use of mechanical units which men direct and of which men are parts. A certain bodily activity is of course necessary to manipulate properly the machines. While some work like shoveling is still propelled by men's muscles, the average man about a mining plant manipulates perhaps 10 hp. The proportion of mechanical as against human power is therefore several hundred to one, and the value of intelligent manipulation needs no further demonstration.

The responsibility for securing this intelligent manipulation lies with the manager. His aim is to produce the most profitable effect from his whole mechanical equipment; therefore he must see to it that each unit composing that equipment does its duty. To perform this

duty properly [illegible] must be worked as near to full capacity as [illegible] for otherwise men and power will be kept busy [illegible] at adequate result.

To accomplish this in mining requires energetic exercise of the sense of proportion, of constructive imagination, and of executive ability. The work in a mine is constantly shifting. A group of men and machines may be well occupied today in a certain stope, but tonight some change may develop which will permit only half the force to be occupied profitably there to-morrow. An exploring drift reaches its objective and that particular piece of work must be stopped; the time arrives when hand tramming is no longer either adequate or economical and mechanical tramming equipment must be installed; or, on the other hand, the supply of ore from a certain shaft has so fallen off that more equipment is in use than is justified by the output.

In any property of considerable size it is impossible for the manager to get into personal contact with all these details. It is necessary therefore to supplement his own activities with an organization so arranged as to keep him informed. Various organizers will call these departments by different names and approach their problems from different angles, but, broadly speaking, we may classify the manager's working force into two divisions:

1. The division of information, which will contain the map-makers, engineers and geologists, the samplers and assayers and the cost and record-keepers. This work is not inherently valuable; it is merely a means to an end. The manager must not make it the field of his own labors; its purpose is to add to his capacity to direct the productive work. It is of course important that this division should not be overdone.

2. The division of executives covering construction engineers and all the operating force.

Proper Supervision of Labor

The limits of this article will not permit much discussion of the various reports dealing with the supervision of labor; but I can briefly point out some of the essentials that must be covered. It is possible to gather the data collected by the division of information into a daily summary which will be at least approximately correct. This will show the following supremely important items:

1. The number of men employed and their distribution in whatever detail is desired.

2. The amount of product obtained from this labor, the quality of this product and the disposal of it.

These facts are decisive as to the efficiency of the job. The expenses of a company are invariably in proportion to the number of men employed. For instance, if at a given mine you employ 10,000 shifts of labor in a given month, and you find that your total expenses were $50,000, it is a mathematical certainty that next month when you employ 12,000 shifts your expenses will be $60,000. In other words, the expense involved in employing a man on the [illegible] ration is $5 per day. This figure once established [illegible] a short cut to your total expenditures which [illegible] at any moment.[1]

[1]The cost per man [illegible] not merely wages; it is the total expense of [illegible] power and administrative effort required [illegible] these items vary within such narrow limits that [illegible] approximate to speak of them as constant. In [illegible] these relations can only be disturbed by a radical [illegible] in the scale or method of operating such as are not [illegible] in these remarks.

The degree to which the manager can digest the details of labor will vary according to the size of the property, or in proportion to the number of superintendents he employs. On a small property the manager is his own superintendent, but on a large one he will have to restrict his observations to larger units, delegating the daily supervision to superintendents of particular fields. Each superintendent must watch his field of operations exactly as a manager does, the only difference being that instead of covering the whole property he only covers a part of it; that he deals with smaller units and has a more intimate contact with the men and products of his special field.

Constant Supervision of Products

Just as a proper record of the employment of labor gives a clear idea of daily expenses, a similar record of the product obtained gives an immediate line on the daily income. One is just as important as the other, but the supervision of product is more difficult and less exact. It involves correct weighing, sampling and assaying—three steps, each apparently simple but really very difficult. While the labor record involves no equipment except paper and pencil, it is not too much to say that the basis for proper accounting of the product lies deep in the design of the plant and the training of the whole technical organization. Proof of this is the care with which these subjects are elaborated in technical mining literature. I limit my observations simply to pointing out where they belong in the business scheme. A realization of the true importance of the supervision of products is the prime technical qualification of a mine manager. Without it he can have no effective engineering point of view and will have to depend on guesswork and rule of thumb.

To get maximum profits it is necessary to work out the following points: What volume and grade of ore extracted daily will cover the total expenses of the company? What grade will cover the cost of mining and smelting, but not necessarily the general and outside expenses? What ores, too low in grade to be a true object of mining, may yet profitably be treated if obtained in the process of development? Which ores should be sent directly to the smelter and which should be concentrated or otherwise treated at the mine or mill? What are the metallurgical losses of all processes, and the extent to which they may be curtailed profitably?

By balancing these factors against one another and against the cost of constructing and operating the necessary plants, the manager finally works out the number of steps of his process and the logical and most economic cost. This cost will naturally be as low as possible in proportion to the money received for the product sold; but a little reflection will show that this is not necessarily the lowest cost per ton of material handled in any department.

This problem is present at all mines. The coal or iron miner who deals with a homogeneous material may find it much easier to solve than the miner of complex ores of precious metals; but it is there just the same, and the intelligent manager will always recognize it.

It is a frequent mistake to suppose that the important facts are revealed by the cost-keeping or accounting system. This is emphatically not the case. A thorough accounting of a month's operations cannot be prepared

before the middle of the following month. This means that the acts of which it is a record are from two weeks to seven weeks old before the record appears. If a manager waited that long before taking action on the changes which develop from day to day he would make himself ridiculous. It is infinitely more to the point to have daily facts presented in usable form, even though some of the information is only approximate.

A discussion of accounting may conveniently follow the preceding remarks because it is important to combat a frequent misunderstanding of its true value. Accounting is not management. Broadly speaking, it is not a function of the technical management at all, but is a function of the board of directors, which should be administered by the financial officer of that body—the treasurer—who is frequently also the recording officer, the secretary. These officers are subordinate to the president, but they are quite distinct from the technical manager, who deals with only a portion of the business. It is the duty of these officers to account to the stockholders and creditors of the concern for the income and outgo of funds and properties. But we should bear in mind a broad distinction between company accounting, which is the business of the treasurer for the benefit of the stockholders and creditors, and department accounting, or cost-keeping, which is essentially a record of efficiency for the benefit of the work itself.

In either department the usefulness of the accounting depends entirely upon how effectively it presents the vital facts. Elaboration of detail where not needed is mere pedantry, which instead of serving the true purpose of accounting helps to defeat it. Simplicity and brevity of statement should be the aim. The figures of a cost statement may be likened to the topography of the country. When you find a vantage point you can see the lay of the land. A man in the cañons at the foot of Pike's Peak might lose himself looking for the summit, but if he walks out on the plain he can see it easily. Likewise in business, the man who wants to know where he is going refuses to bury himself in a maze of figures. He tries to keep before himself the general outline of his problem in order that when he plunges into detail he may still not forget the relative size of things.

Unit Costs as Operation Guides

In the general accounting of a company's business all figures are stated necessarily in money. But in cost-keeping or department accounting an eye should be kept not only on money values but also upon the things which the money represents. The work is done by labor aided by mechanical power, by explosives, by timber, tools and other supplies. The efficiency of the job is exhibited even more decisively when shown in terms of these elements than when shown in dollars and cents. For instance, Nevada Consolidated Copper Co. reports that the average amount loaded per steam-shovel shift is 1472 tons, but that the maximum loaded was 6784 tons. The average time each shovel was actually at work was only 30% of the working day. It is plain that their operation is frequently interrupted and that efficient operation has much to do with minimizing those interruptions. The manager may have found that the cost of increasing the working time of the steam shovel would be too great to justify it. While he might increase the output per steam shovel, he might decrease the output per man. He would then lose money. But if he can increase his output per shovel by increasing his concurrent cost in less proportion, he will gain. We have thus reasoned back to the conclusion that the work of the steam shovel is not the decisive criterion of efficiency, unless we include with it everything needed to make its work complete.

Lowest Costs Per Man Not Always Best

To illustrate this let us take the whole situation just outlined. Nevada Consolidated employs 611 men all told and eight steam shovels working two shifts each. The number of men actually attached to each shovel is only about 17 for both shifts, and it burns 5.7 tons coal per day. With labor at $4 per day and coal at $5 per ton the cost of the steam shovel is about $100 per day, and its output is 2942 tons for the two shifts. But the total number of men employed is 611 and the cost is, say $3055, or $5 per man. Eight steam shovels are employed, the total output being 23,852 tons. Suppose we employ another steam shovel and get half as much from it as we get from the others. We have increased our cost by $100 a day and our tonnage by 1472. The total number of men is now 628 and the total cost $3155. The cost per man is now $5.02 per day, which is very close to what it was before. But the output has risen from 23,852 tons to 25,324 tons. Per man it has risen from 39.04 to 40.32. The difference does not appear to be great in either cost or output, but proportionately it is, for with an increase in cost per man less than 0.5%, the output per man has increased over 3%. Thus the increase of output is about seven times the increase of cost. Let it be remembered that in doing this we are decreasing the averaging efficiency of the steam shovels. This indicates that the cost per man is much more stable than the cost per shovel.

Now, applying this discussion to the cost-keeping problem, we come straight back to the vital importance of making the statements indicate the decisive facts which prove efficiency. What these facts are needs to be worked out for each property. I have found it beyond my powers to make a general statement that will apply everywhere. While it is true that the output per man is a most important figure, it is equally true that it must be applied only when modifying factors are clearly understood, and then only to the proper units. It has been shown that a mistake would have been made in assuming that a steam shovel taken by itself must be run at full capacity, regardless of other things. The fact is, however, that instead of bringing in the full normal equipment that goes with a steam shovel we only brought in a part of it. The eight shovels employed 611 men, or 76 each; but with nine shovels we only had 628 men, or 70 each. The point brought out was that the machine itself is relatively unimportant so long as it does not alter the normal scheme of things. In keeping the cost of operating that shovel it would be a great mistake to rivet attention on the engineers, cranemen, and firemen, and the amount of coal it burns and the supplies it uses. The real unit is the shovel combined with the locomotives, tracks, cars, railroad and dumping facilities. The force required to operate such a unit night and day is generally 75 to 100 men, and not the 15 or 20 men working on or about the shovel. When this fact is got straight the true unit cost is made effective.

It is an axiom that each operating unit should be worked as nearly as possible to its full capacity. The converse is that where the output is limited at some point—as, for instance, by the capacity of a mill—the units required to supply that output should be cut down to the smallest possible number. A shaft is such a unit. The cost of a shaft and the maintenance of its hoisting, hauling, pumping, lighting and compressed-air equipment, its railroad trackage, shaft houses and shipping equipment mean a large amount of fixed expense. Whenever it is found that a number of such shafts can produce more than the required output, economy demands that some of them should be ruthlessly shut down in spite of the apparent waste. The truth in such a situation is that capital has been wasted in providing unnecessary equipment, but that is no excuse for wasting still more money to operate it. How often situations of this kind arise it is hard to say. One example is found in some mines in Southeast Missouri, where a few years ago 24 shafts were used to supply 2,300,000 tons a year. Now eleven of the same shafts supply 3,200,000 tons a year. Thirteen shafts with abundant ore reserves are rotting and rusting at a saving of possibly $1,000,000 a year.

Estimation of Major and Minor Units

In the whole process of organization there are controlling limitations. The company itself is limited in its activities by its capital and its opportunities. Its properties are each limited in some way—the output of a mine by either its own capacity to produce or by the capacity of a mill or smelter or market. These limitations are extremely important in calculating the size and number of concomitant units. Minor units make up major ones, and the effectiveness of each within its sphere becomes highly important once that sphere is established. There is a certain subtlety about these distinctions that is worth dwelling upon.

The cost of power, for instance, is an important thing in a mining property, but its unit cost is capable of being misapplied. The power plant properly should deliver the minimum output required for the work. The proper aim is not cheap horsepower but cheap work. In one case a plant was supplying compressed air and electric power at a cost of 1c. per kw.-hr., while its neighbors were making power at 1.25c. per kw-hr. But at this plant the cost of power per ton of ore was 45c. and at its neighbors' only 25c. The superintendent was astounded when brought to task for his high power costs, pointing to his low cost per hour. The fact was that the power was being wasted. Efficiency at the engines did not excuse leaky pipes, scattered and inefficient pumps, and machinery used where it was not needed. Accounting, with the emphasis on the wrong point, was exhibiting a false economy, which was costing the company in reality $80,000 a year.

But the mere fact that the kilowatt-hour is a minor unit does not destroy its importance. It is important to make cheap power, but the supply must be limited to the requirement. Any additional power made is a waste, no matter how cheap it is.

It would be a false economy, likewise, in order to show a low consumption of drill supplies, to let them run in bad repair, or, in order to show a low consumption of compressed air per drill, to use more machines than necessary and let them stand idle part of the time. The true result to be reached is cheap ore breaking and not cheap supplies or cheap air per drill. That fact, however, does not in the least argue against economy in both these items—economy rightly applied to its proper unit.

Big Things vs. Little Things

The argument leads to one principle that should underlie effective organization, namely, that big objects take precedence over little ones. It is a theory with some people that if you "take care of little things the big things will take care of themselves." This is like starting in to make an automobile by first making the screws and bolts. It is an utterly illogical and ineffective theory. The first essential of an automobile is a design—some plan by which a vehicle can be made to serve a certain purpose, have a certain appearance and attain certain speed. This design involves the use of definite mechanical principles which must be satisfied by the creation of essential mechanical entities—the motor, running gears, wheelbase, etc. The mass of detail work which follows must be adapted to the essential scheme and grow out of satisfying the needs of that scheme. Success depends on the nicety and intelligence with which the details are worked out. A lot of work can be put on the paint, but the paint is not wholly essential. It is well to remember that the car will go just as fast and ride just as easily whether the paint is black or white. But when the car is sold the color of the paint may decide the buyer for or against the whole car, and may therefore determine its commercial success or failure. Some people will argue that this proves the vital importance of this small detail. But the manufacturer is entitled to answer: "Our design is to create a car that will sell; we are merchants as well as engineers. To please our customers is a prime essential; the color of the paint is a trivialty. Our customers cannot decide fundamentals of construction, but on this point their judgment is controlling. By our theory of doing business we are bound to accept their decision."

Thus the question is decided not in the least by virtue of minute detail in itself but by the application of a cardinal principle. The true organizer will neither disparage nor overlook details, but he will be their master and not their slave. He will not love them for their own sake, but will use them to further his plans.

*

North Carolina Metal Output

North Carolina easily retained first rank in gold output among the Eastern or Appalachian States in 1914, the yield having been the second largest in the last 10 years. The total production of gold in 1914 amounted to 6343.94 fine ounces, according to the Geological Survey, the value of which was $131,141.

The gold was obtained from 12 placers and 9 deep mines, but several of the mines made a very small production. The largest producing placer was the Bigger-staff, in Rutherford County. The Iola mine, in Montgomery County, had the largest yield of gold from deep mining. Other mines which contributed an appreciable part of the gold output were the Rich Cog and Uwarra mines, in Montgomery County; the Gold Hill, in Rowan County; and the Howie, in Union County.

The silver output of North Carolina, recovered as a by-product from gold milling, was 1524 fine ounces, valued at $843, against 1812 fine ounces, valued at $1095 in 1913. The copper production in 1914 was 20,434 lb., valued at $2718.

Piegan-Gloster Cyanide Mill

By Alexander McLaren*

The Piegan-Gloster, of Marysville, Mont., is one of the many gold properties characteristic of those old mining camps which, after years of idleness, are once more experiencing activity because of the more economical and efficient methods of mining, milling and cyanidation of the present day. This property is situated about three miles from Marysville, Mont., and is owned by the Barnes King Development Co. The ore is delivered to the mill from the mine over 1400 ft. of Riblet two-bucket aërial tramway, dumping into a receiving bin on the same level as the mill bins. From this the ore is fed to a No. 5, T. L. Smith short-head (gyratory) primary crusher by a belt conveyor. This crusher breaks from mine-run down to approximately 1¼-in. ring and the ore is then elevated by a continuous-bucket elevator to an automatic sampler at the bin head, then by a distributing belt conveyor to the main or mill bin.

From the mill bin the ore is fed to three Lane slow-speed chilean mills by Stephens-Adamson automatic belt feeders. The mills are 10 ft. in diameter and each one handles approximately 50 tons of ore per 24 hr., performing the crushing in cyanide solution. It may be said that the ore is slightly harder than the average quartz. A 6-in. overflow discharge is used with a strip of ordinary fly screen to withhold the chips and prevent clogging the pulp pipes. The consistency of the pulp is 4½ parts of solution to 1 of solids. The combined output of the three Lane mills is carried by launder to a Wilfley roughing table, the concentrated output of which drops to a Wilfley finishing table. The product is a black sand with some coarse gold, and is treated by amalgamation in a cleanup pan. The overflow from both the roughing and finishing table goes to an Akins classifier for further separation.

The sands proceed to one of a series of leaching tanks, 10 ft. staves and 26 ft. in diameter, the unloading of which, after treatment, is performed by flushing. The slimes are taken to a 24-ft. Dorr thickener, 7 ft. deep, from which the thickened pulp is transferred by diaphragm pump to one of a series of Dorr agitators 16 ft. diameter by 14 ft. deep. These agitators are not connected in series, the charge method being used. Overflow solution, prior to going to zinc boxes, is filtered in two small tanks through a layer of sand. Zinc shavings are used as precipitant.

One 40-hp. motor drives three Lane mills, two concentrators, one Akins classifier and the pulp distributor for the leaching tanks. In this mill, after considerable experiment on the part of the management, the slow-speed chilean mill has been found far superior to the stamps formerly used. The advantages are less wear and tear; less power consumed per ton of output; a pulp better adapted to cyanidation and water consumption nearly 80% less than that required by stamps for crushing. Less operating vigilance is required.

CRUSHING INSTALLATION OF LANE MILLS

Rescinding Purchases of Mining Property

By A. L. H. Street*

Under a decision of the Kansas City Court of Appeals, a purchaser of mining property cannot rescind the transaction on account of misrepresentations made by the seller to the purchaser's agent concerning the character of the property, if the agent was not deceived by such misrepresentations or did not rely upon them. The court says: "Applying the rule that an attempt fraudulently to deceive must be so far successful as to have induced belief and reliance on the part of the person claiming to have been injured, we find that plaintiff's case failed."

It is further held, in the same opinion, that one induced by fraud to enter into such a contract must promptly elect to rescind on discovering the fraud, or his right to cancel the purchase will be deemed to have been waived. (Greenstreet vs. Walsch, 176 Southwestern Reporter, 1062.)

Exposition of American Chemical Industries—The first American exposition of chemical industries will be held at Grand Central Palace, New York City, during the week beginning Sept. 20, 1915. It is to be managed by C. F. Roth and A. Nagelvoort, assisted by an advisory committee of nine eminent chemical engineers. It is expected to include coal, wood and petroleum products, metals, minerals, water and sewage purification, air and gas processes, glass and ceramics, oils, varnishes, plastics, rubber, leather, glue, etc. Working exhibits will be shown. Inquiries should be directed to the National Exposition of Chemical Industries, 46th St. and Lexington Ave., New York City.

Orebodies of the Mesabi Range—III

By J. F. Wolff*

SYNOPSIS—Methods of exploring Mesabi orebodies. Combination diamond-churn drill outfit used. Holes spotted on definite systems. Continuation and extent of drilling based on results obtained as work progresses. Vertical sections constructed through lines of drill holes. Correlation of beds cut by the several holes. Division into layers and connecting between holes. Precautions to be observed.

The first explorations in the Mesabi district were carried on by test pits. The depth of these was limited to the level of the groundwater. In several cases where test-pitting developed a fairly large body of ore, shafts were sunk and the orebody developed more completely both in depth and laterally by underground workings. Several bodies explored by test pits were developed as openpits, having shafts and a few drifts and crosscuts for drainage purposes. In the middle '90s diamond and churn drills were introduced for exploration work and have been used for such work ever since. Some mining companies do their own exploration work, but a great deal of contract work is done also. Although such work is expensive, the total cost in any extensive explorations is but a few cents per ton of ore developed, this includes drilling on barren properties. As will be shown later, the drilling is so thorough and systematic that the shape and extent of the orebody are determined with extreme accuracy. Obviously such information is invaluable in the proper planning of development work, whether openpit or underground. It will be shown here how to interpret drill explorations properly, and how to work out the shape of the orebody closely from such records.

The drilling outfit will be described, as it is well known to most mining [illegible] detailed description of both outfit and drilling operations in the University of Minnesota bulletin mentioned in Part I. The accompanying illustration, Fig. 21, is a good view of the ordinary Mesabi drill outfit.

A brief account of drilling operations is appropriate, as they must be considered in interpreting drill records. A 3-in. casing pipe is first driven down through the glacial drift, locally called "surface." The drift is full of boulders of all sizes, which are blasted when encountered or are drilled through with diamonds and then blasted. Before blasting, the casing pipe is pulled up a few feet to prevent its bottom from being broken by the blast. The surface is churn-drilled and washed up out of the casing pipe after every few feet of advance of the casing. A 200- to 300-lb. cylindrical weight is used as a drop hammer to drive down the casing pipe. When the ore is encountered, the casing is driven down into it a few inches so that the surface material will not run down under the end of the pipe and become mixed with the ore sample. A 2-in. casing pipe is then put down inside the 3-in. and churning proceeds in the ore just as in the surface. Samples of the ore are taken for intervals of 5 ft. as the drilling proceeds, unless rock is encountered, in

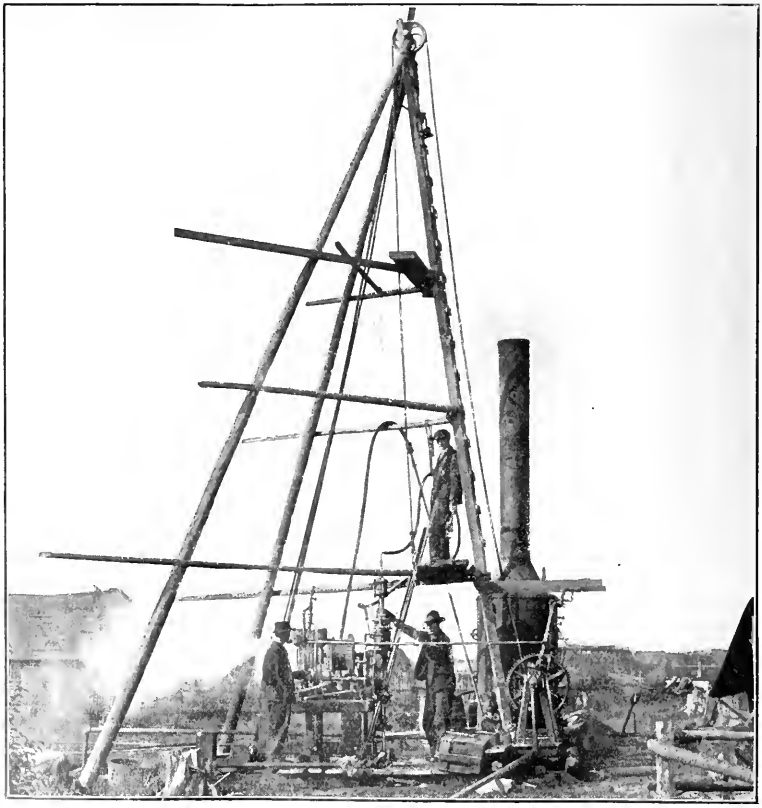

FIG. 21. STANDARD MESABI DRILLING OUTFIT

*Mining engineer, Oliver Iron Mining Co., Duluth, Minn.

which ease the drill runner attempts to chop and blast through the rock. Often the rock is only a thin seam and can be cut through with a chopping bit, but if it proves to be a thick layer of taconite the chopping bit is taken off and the diamond bit put on. Then diamond drilling proceeds until ore is again encountered or until the engineer in charge of explorations decides the hole is deep enough. If more than 5 ft. of ore is encountered under the taconite, the entire depth of the taconite is blasted so that the easing pipe can be driven down through it to the ore beneath. This operation is known as blasting down easing. After the casing has been driven down to the ore under the taconite, churn drilling proceeds as before until the bottom of the ore is reached. The depth to which drilling in taconite is carried depends entirely upon geological conditions, depth of ore in adjacent holes or depth of nearby orebodies, except in case of special contracts or leases in which a specific depth in taconite is provided.

Samples Taken for Each Five Feet

In taking samples of the ore, the choppings or sludge for each 5-ft. sample is caught in three or more barrels as it is washed up through the casing pipe and is allowed to settle for two hours, after which the water is drained off and the settlings collected in a pan and dried. The sample is then divided into a number of parts to provide samples for the mining company, the fee owners, etc. These are sent to the laboratory and analyses of the material dried at 212° F. are generally made for iron, phosphorus and silica, and by some companies for manganese and alumina. Pieces of the core from that part of the lode which was diamond-drilled are saved also. The different mining companies have different methods of preserving samples, some using paper bags, some glass bottles and some specially constructed tin boxes which can be packed or filed away easily. The drill runners make reports of the material encountered to the director of explorations, generally an engineer, giving also the depth of material diamond-drilled. The chemical determinations of all samples are also reported to the exploration chief. The actual samples, choppings and core are examined by him and the material classified as to its character, whether ore, taconite and ore, paint-rock, taconite, slate, quartzite, etc. He also checks the depth of diamond drilling reported by the drill runner. From this information, that is, chemical determinations and physical classification, the record of the drill hole is platted on tracings together with records of all other drill holes on the forty.

Location of Drill Holes

The unit of ownership is a 40-acre tract, therefore the unit of exploration is generally a 40-acre tract. Before drilling is started on any property a system of drill holes is laid out on a map of the property and then staked out on the ground. Different systems are in use by different companies and each has its advantages and its adherents. No one system can be prescribed as the best for all parts of the range. The more irregular and rocky orebodies require more closely spaced drill holes. In some of the early explorations drill holes were spaced 150 to 200 ft. apart. In many cases no regular system of spacing drill holes was followed. The system most widely used at the present time and for some years past is to spot drill holes at intersections of north-south and east-west lines 300 ft. apart, giving five rows of holes each way or a total of 25 drill holes per 10-acre tract. If the property adjoins an ore-bearing property so that something is known of the possible position of an orebody the drilling is started in that part of the forty where the orebody is suspected. If nothing is known as to the probable existence of ore on the property at least five of the 25 holes are drilled. One of these holes, the one nearest the outcrop of the quartzite is drilled through the iron formation to quartzite. If no ore is encountered in any of these holes the exploration is discontinued temporarily. If the mining company controls the surrounding properties and upon exploring them finds ore near the property lines of this property in question, exploration is resumed on the abandoned property. If ore is encountered in one or more of the five drill holes which were drilled first, others of the 25 locations on the forty are drilled and the explorations are continued until the outline of the orebody is well established. The engineer in charge of explorations studies the results of the drilling carefully as it progresses and if he considers it

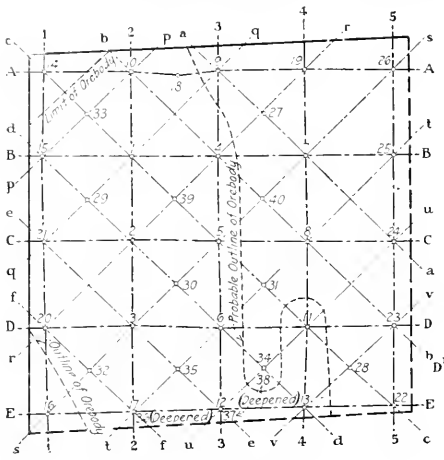

FIG. 22. TYPICAL EXPLORATION OF FORTY-ACRE TRACT

necessary, for determining either the depth of the ore or the outline of the orebody, holes intermediate between these 25 locations are put down. Even in cases where the orebody covers the whole 40-acre tract it is not always necessary to drill all of these intermediate holes. A close study of the structure of the orebody by the engineer determines the necessity of these holes. However, if all of these intermediate holes are drilled the distance between drill holes will be 212 ft. This may seem to be excessive exploration, but experience has proved that drill holes even 200 ft. apart are not too close. In many instances rock horses have been found in the orebody within a few feet of a drill hole and none of the drill holes showed any rock intrusions.

The system of drilling only five holes and abandoning the property if these show no ore is not universally used, nor is it to be recommended as the best practice, because small narrow bodies might occur between such drill holes. As a rule, at least 10 of the 25 locations ought to be drilled before abandoning the property. This of course depends much on the position of the property and is applicable particularly to properties near the center of the iron-formation outcrop or north of it. For those proper

ties near the Virginia slate five barren holes is a reasonable test.

As the drilling progresses sections are prepared to a convenient scale (40 ft. or 50 ft. to the inch) looking north and looking west. Thus there will be five east-west and five north-south sections showing the 25 holes originally laid out. If the intermediate holes are drilled, additional sections are made, looking northeast and northwest, giving two sets of diagonal sections, and the east-west and north-south sections are discarded, except such of them as may have drill-holes not shown on the diagonal

sections, such as a section along A.A, Fig. 22. Positions of drill holes and of sections are shown on the plat of Fig. 22, which represents a 40-acre tract explored as just described. From a study of these intersecting sets of sections an accurate knowledge of the shape, extent and structure of the orebody can be obtained.

In making a section the drill holes are platted in their proper relative locations and elevations, the latter data having been obtained previously by field engineers. The elevation of Lake Superior is the common datum plane generally used by many of the mining companies. Some companies use sea-level datum. Opposite each drill hole on the section are recorded all analyses and the classification of material. Fig. 23 shows an actual section of an orebody as developed by drill records. The chemical analyses and classification of material are shown. With the drill records thus made into sections, the structure of the orebody is worked out. Two general divisions of ore material are made. Churn-drilled material analyzing below 49% or 50% dry iron is classed as lean ore. Churn-drilled material analyzing above 49% or 50% dry iron is classed as standard ore. This, however, does not mean merchantable ore. The standard ore is further subdivided into bessemer and nonbessemer. The criterion for bessemer ore is not absolutely rigid with all companies, but an ore in which the ratio of phosphorus to iron is 0.00075 to 0.00080 is classed as bessemer; 55% natural iron, equivalent to an ore carrying 62.50% dried iron and 12% moisture, with 0.045% phosphorus, is the market standard or base for iron in the bessemer class. Of course ores somewhat lower than this in iron are sold as bessemer in the market. Most engineers in the district have been in the habit of working out the structure of the ore by joining up ore layers of similar classification lying approximately in the same horizon in the orebody and connecting the bottoms of the ore in adjacent holes either with straight lines or with regular curves. In many cases this procedure is approximately correct, but in others it leads to erroneous results.

The following description will outline the most recent and accurate method for determining the structure of an orebody. Having at hand all the cross-sections, the engineer examines the cuttings and core samples of each drill hole and divides up the entire hole into the different structural layers as shown by the sections in Parts I and II. These layers are upper blue or high-grade ore, upper yellow, nonbessemer, ore, intermediate paint-rock layer,

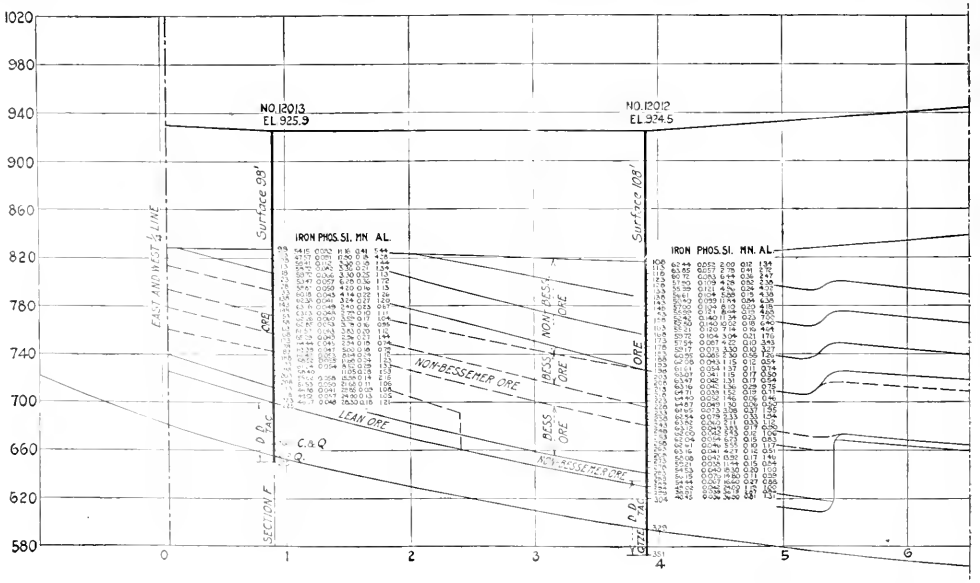

FIG. 23. SECTION OF A DEVELOPED OREBODY

lower yellow, nonbessemer, ore and lower blue or high-grade ore. The high-grade ores are generally high in iron, though not always so, and generally low in phosphorous, though not always bessemer ore. In making this division, all the drill samples, choppings and core, from a hole are laid out in order on a long table and divisions made largely from physical appearance. The paint-rock is characteristically reddish and the yellow layers are yellow. The chemical analyses help considerably in this classification also. The paint-rock layer generally is noticeably high in phosphorus and alumina, the phosphorus ranging from 0.075% to 0.300% and the alumina from 4% to 8 or 10%. The break between lower yellow ore and lower blue ore usually is marked by a sharp drop in both phosphorus and alumina, the blue ore being the lower in both elements. The division between upper yellow and upper blue ores is marked best by a drop in phosphorous, the blue ore having the lower phosphorus. This division is not so universal as in the lower orebody. The alumina in the two layers is about the same. Of course exceptions to these general statements are not uncommon.

The descriptive terms, high-grade ore, blue ore and yellow ore should not be taken literally. In the yellow-ore layers considerable red or purplish paint-rock material may occur; in the intermediate paint-rock layer, which is usually of reddish appearance, layers of yellow ocher occur, and in the high-grade or blue bodies there are found layers of paint-rock and brown ore. The terms blue ore, yellow ore and paint-rock are here used simply to describe structural layers. This division into layers is not always easy to make, but as stated in Part I the division between intermediate paint-rock layer and lower yellow ore is sharp and always can be made easily. In fact the experienced engineer usually can pick this division from the chemical analyses and classification of material. The upper 5 to 15 ft. of the lower yellow layer, just below the paint-rock layer, frequently is sandy ore or decomposed taconite. On the Western Mesabi it is almost pure sand. In any well-concentrated orebody drill holes can be found which can be divided accurately into the aforementioned layers, and will give the average thicknesses of the respective layers. With such data as a guide the other drill holes can be divided into the several layers, and such classification can be carried out even in the holes drilled in barren rock. In some well-concentrated orebodies further subdivisions can be made. The lower blue body can be divided into a bottom body of decidedly blue ore and

an upper brown ore, the gradation downward from the lower yellow ore. In the upper blue body an interbedded red or yellow slaty or paint-rock ore can be distinguished, being the alteration of the upper interbedded slate layer mentioned in Part I and shown in Fig. 6.

How to Correlate the Strata

When all of the drill holes have been thus divided into their structural layers, the structure of the orebody can be worked out accurately by connecting corresponding layers in adjacent drill holes on each section. Account must be taken, of course, of preglacial erosion, of slump in the orebody and of the effect of rock layers or rock horses in the ore, in connecting these structural layers. In some small orebodies which are alterations of only part of the upper taconite, and in which only a few or none of the holes have been drilled down through the Intermediate slate, the structure can be determined accurately by examining all the drill-holes for layers of slate or taconite having distinctive characteristics, and correlating and connecting such layers on the sections. Fig. 24 is a plat showing location of drill holes and lines of the sections, and bottom of ore contours of the main part of an orebody whose structure was accurately worked out along the lines described. Figs. 25, 26 and 27 show the principal east-west and north-south sections of this orebody. This plat and these sections are worthy of careful study by engineers of the district, as they combine many essential points in the working out of structure.

Attention is called to the dip of layers of rock south of the orebody. This was obtained by observing the dip of the cores of slate, particularly of the Intermediate slate layer. For this purpose a clinometer or a triangle divided into 5° angles can be used. In this particular case the dip was found to be from 15° to 23°. The strike of the formation is 55° E. as shown by the surface geological map in the vicinity. The dip observed from the drill cores was the maximum dip, at right angles to the strike. By a simple computation the dip on a north-south section was determined to be from 9° to 14°. One must take care in determining dip from rock cores not to use dips of ore seams in the taconite, because these may differ considerably from the dip or bedding of the whole formation. The slate cores give the best bedding and dip.

Attention is also called to drill holes 16, 20 and 21 which are near the south rock-wall of the orebody. Observations of slate cores found in the samples from these drill holes showed a dip of about 5°. Since the average dip of the rock south of the orebody is about 19° the small dip of 5° in these drill holes is taken to mean that the dip is down to the north and that these holes are north of the south rock-wall of the main orebody. On the sections it can be seen that these holes contain a great deal of rock, which is further evidence that they are near the limit of the ore. Furthermore the analyses of the ore in these drill holes was low in iron and fairly high in silica as compared with the drill holes to the north in the main part of the orebody. All this evidence was used in locating the line of the south rock-wall as shown in Fig. 24. Of course this information may be interpreted differently by different engineers, but it is presented here to call attention to facts and data which are not taken into consideration by most engineers in developing structure. Obviously the exact location of a rock wall is a matter of considerable importance, particularly in the development of openpits. In many cases considerable rock area might be stripped unless the drill records are studied carefully and interpreted along the lines just indicated.

The orebody shown is unusual in that the layers have so pronounced an initial southerly dip. The average dip of the iron formation is only 6° to 7°, instead of 19° as in this case.

In working out structure it is not entirely necessary to divide the orebody into all of its different layers; in fact it is often difficult to do so; but it is always possible to determine the division line between the intermediate paint-rock layer and the lower yellow ore, and with this division established on all sections as a guiding structural line, the essential structure can be worked out by drawing all ore layers shown by drill-holes on lines parallel to this structural line. In applying this rule the engineer must bear in mind the effect of rock layers and pillars and slump in deep parts of the orebody.

Good Drilling Makes Easy Work

After the deposit has been divided into its structural layers on the sections, the bodies or layers of lean ore and standard ore and bessemer and nonbessemer ore can be connected. The great value of the structural work really consists in being able to connect these different grades of ore with the certainty that they exist in the ground approximately as connected on the sections. Since the Mesabi iron formation is sedimentary, the alteration and concentration have proceeded along bedding planes, and lean layers or high-grade layers do not connect across the bedding. Therefore the great value and importance of this structural work should be apparent. It can hardly be over-emphasized. It is not only important in openpit development but is even more important in planning underground drift systems. One can easily see that if the structure is not worked out properly drifts may be planned which will drive into rock where ore was anticipated, and *vice versa*. Furthermore during the exploration of a property this structural study is a great aid to exploration and in fact is the best way to direct exploration. Such structural study shows plainly to the director of exploration where additional holes may be necessary or where some proposed holes may be superfluous. A case in point may be seen on Fig. 24; a drill hole intermediate between drill holes 18, 19, 25 and 26 and one say 100 ft. north of drill hole 22 would locate quite accurately the actual south rock-wall of the orebody shown on this plat.

Important to Supplement Drill-Hole Records

With the structure accurately determined as outlined, mining operations, whether openpit or underground, can be conducted much more skillfully than could be done otherwise. Development and mining work, whether test-pits, steam-shovel cuts, or underground drifts and raises, will give additional information as regards the structure, and all of this can be correlated and used to supplement the structure as shown by the drill-hole sections. Especially in openpit work is it necessary to keep in mind the ore structure in estimating the grades of ore which will be produced in a certain season. Of course most mining companies supplement the drill records by sampling the cuts made by the shovels and by test-pits, but to be of value all such information must be correlated structurally.

(To be concluded)

Details of Practical Mining

Wood vs. Steel Mine Ladders

By George E. Collins*

In the *Journal* of May 29 is a note with sketch by my friend E. S. Wiard, about steel ladders used at the Capital mine, Georgetown, as to which I wish to suggest a word of warning. In most mines such ladders would be unsafe. Moisture is apt to collect behind the rungs where the latter are riveted to the sides. This results in rust, and when the rivet has rusted through the ladders are very dangerous, as the defect is not visible. Steel ladders should be used only where liability of dry rot renders wood unsuitable; and even then I believe a design in which the pipe rungs actually pass through the sides would be safer and more generally preferable. Even in a dry mine there is usually moisture enough to develop rust on metal surfaces, especially when two such surfaces are in approximate but not actual contact.

In my experience, light weight in ladders is ordinarily a matter of secondary importance. Where a length of

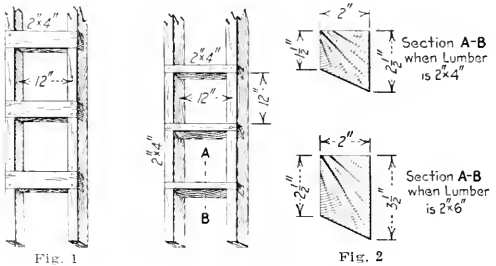

Fig. 1 Fig. 2

LIGHT WOODEN MINE LADDERS

ladder has to be moved frequently, very light ladders will of course be built. Ladders are intended primarily to travel on; and next to safety, convenience in climbing is the most important requisite. Pipe or other metal rungs are cold to the hands, and when wet and gritty cut the skin more than wooden rungs. Moreover, pipe is slippery and does not afford so good a grip for the feet as wood.

In most places, wooden ladders are best. Probably the most generally suitable design, taking convenience and cost into consideration, is that shown in Fig. 1, where sides and rungs are both made of 2x4 stock, the rungs being inset 1 or 1½ in. into the sides. If neatly made of dry lumber, the rungs swell when wet, so that they are firmly held in the slots, even if the nails with which they are originally secured should rust out. Worn rungs are easily replaced—an important consideration, for the neglect of which there is no excuse—and even when a rung is worn through or broken, the pieces hold sufficiently for safe travel. Such ladders made of red spruce, at a high-altitude mine in Colorado, cost 10½c. per foot complete as against Mr. Wiard's figure of 25c. per foot for the steel ladders. Their life, apart from damage by falling rocks—which in my experience is equally destructive to the 1- or 1½-in. pipe—is very long, sometimes exceeding that of the mine itself.

Where the ladders are exposed to the drip of acid water, I have used the form shown in Fig. 2. Here the rungs are made of 2x4 or 2x5 lumber, sawed on an angle lengthwise, so as to make pieces of the section as illustrated 1½ in. one side and 2½ in. the other, when sawed from 2x4 lumber, or 2½ in. and 3½ in. respectively, when sawed from 2x6 lumber. In either case, one cut in the side pieces is made at right angles and the other obliquely, so that the rungs are firmly held without nails. Of course the flat side of the rungs is placed uppermost. These ladders cost but a trifle more than the first mentioned.

Where there is liability of dry-rot, I have used 2x4 lumber for the sides and old pipe sawed into lengths for rungs. If the holes in the sides are a tight fit, no other fastening is necessary. I do not know why wooden uprights last so much longer than rungs—to a greater extent than the increased section would suggest—but such, in my experience, is the fact. The sides might be dipped in creosote or treated with copper sulphate, although I personally have not tried either. Either preservative used on wooden rungs, would be a nuisance.

The facility with which the sides of wooden ladders may be spiked to timbers or fastened to one another by means of cleats is much greater than that by which steel ladders can be suitably fastened by hooks or staples. Of course the advantage mentioned by Mr. Wiard, of each section being supported by the others, may and usually does apply to wooden ladders as well as to those made of steel.

In the old district of Gilpin County, ladders usually have sides of 2x4 lumber, with rungs made either of round 1¼-in. hardwood or of 2x2 native lumber chamfered at the edges and turned down at the ends to 1¾ in., which fit closely into a round hole of equal diameter in the side pieces. A nail through the side into the rungs at each hole adds some further security. These are good ladders to climb, but are not quite so safe as those made of 2x4 slats nor so durable. They retail at the rate of 12c. per running foot.

Slats made of 1x3 or 1x4 are sometimes used, but are not strong enough, and give poor footing. They should be used for movable ladders only.

*Mining engineer, Boston Building, Denver, Colo.

Why Is a Stinker?

The large volume of poisonous gases produced by the burning of a powder charge in a drill hole and delicately designated as a *stinker* is also similarly produced from causes other than burning of the charge. If the explosive has aged to such an extent that its sensitiveness has materially decreased; if the explosive is in a frozen or partly frozen condition, or if too weak detonators are used, an incomplete and improper detonation of the charge will

result and an unusual volume of poisonous gases will be given off. Many of the burned-out holes which are unexplainable, in view of the care taken in making the primer, selecting the fuse and loading the hole, are in reality not burned out at all, but simply the result of incomplete and improper detonation from one of the causes enumerated.

Rocker and Grizzly Mining on the North Saskatchewan

By J. A. Macdonald*

The newly discovered placer mining on the North Saskatchewan River which is now being vigorously prosecuted by the rocker and grizzly methods, recalls the early days of the Klondike when those crude implements were the only methods of mining the gold of the Yukon where today the mighty dredge does 75% of the mining. In the early days the "dirt" being rich, there was big money for the miner and prospector in operating the rocker, the grizzly and the sluice-box. One hundred dollars a day was not an uncommon output for the Yukon miner in the late '90s, and anything less than a "10c. pan" was not worth bothering with. The rocker and the grizzly are used yet to some extent in the Yukon, but the sluice-box has largely taken the place of those appliances where hand-mining is still pursued.

The grizzly is a modification of the sluice-box; it is in fact a section of a sluice-box, and is used where running water is not available. The rocker is a cruder affair, and is now chiefly used by the prospector in determining the value of a find. Running water is not necessary with the rocker, for the water can be used over and over again.

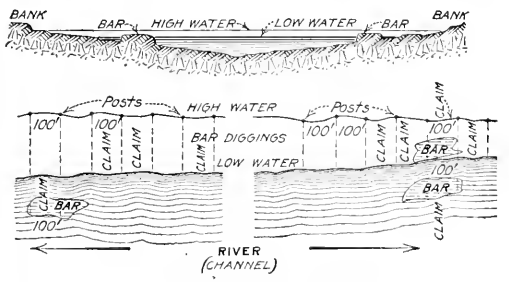

FIG. 1. LAYOUT OF CLAIMS

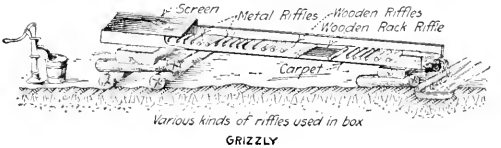
In the new diggings on the Saskatchewan, the grizzly and the rocker are the only methods thus far used. There is plenty of water in the Saskatchewan, it is true, but in order to use it for sluicing expensive machinery is required. These diggings known as "bar diggings" and "tidal diggings," can only be operated in certain parts of the year; that is, when the water is very low in the river; so it would scarcely pay to install expensive machinery. "Bar diggings" are covered with water until fall, when the bars are exposed and digging for gold begins. With the freeze-up the work stops, of course, only to begin again just before the ice breaks up in the river previous to the spring floods. Before the last freeze-up between two and three hundred claims had been taken up, and large numbers of claims have been staked out since.

Along the bank of the river only 100 ft. is allowed any one prospector. These narrow claims may, however, extend out a considerable distance over the flats and bars. The "shore" of the river may extend out in some places several hundred yards, and "bars" show up in areas of an acre or more at low water. These bars and banks are where the gold is found mixed with the fine earth and sand. The layout of these claims is given in Fig. 1. New regulations covering those placers have had to be issued by the Mines Department of the Interior. By the general mining regulations in the Western provinces and the Yukon a mining claim for gold or other precious metals is from 500 to 1500 ft. in width. Here, however, the width is but 100 ft.

In order to prevent the speculator, with no intention of working them, from acquiring valuable claims, the Government regulations provide that any person who, having staked out a claim, ceases work for three consecutive days during the working season sacrifices his claim, unless a "lay-over" has been granted him by the mining recorder. This regulation is very necessary and quite fair.

In Fig. 2 a sectional view of the rocker is shown. It is a box-like contrivance about three feet long by two feet wide, with a separate box or "hopper" on top, and stands on rockers, similar to those on the baby-cradle, hence the name. Inclined shelves covered with blankets to catch the fine gold are placed inside the box. The illustration shows but one in addition to the inclined bottom, but sometimes there are two or more, all covered with blankets. The bottom incline is covered both with blanket and riffles. The water at the outlet is usually held in place and used over and over again. The bottom of the upper box or hopper is perforated with holes about ¼ to ½ in. diameter and is usually of metal. Sometimes the bottom is heavy galvanized netting, which allows the fine gravel to fall through and the rough dirt and stones to be thrown out. Water is added to make a thin grout, and in this grout is the free gold, which is collected as it falls on the blanket and on the riffles. The rockers are necessary to agitate the wet dirt and



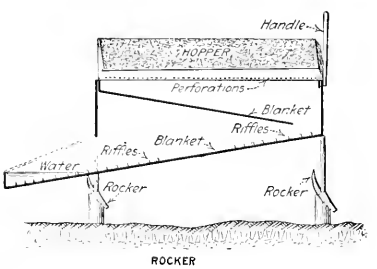


FIG. 2. DETAILS OF ROCKER AND SLUICE BOX

*Box 83, Ottawa, Ont.

water in the hopper, so that the finer parts may work through. There is a handle to the rocker with which the operator works or "rocks the cradle." At the same time he adds fresh water to the hopper, taking it from the spout with a long-handled dipper. Not much water is needed.

The rocker is placed on two posts set in the ground, as shown, or is placed on scantlings, if obtainable. There is a short bolt in the center of each rocker which enters into a corresponding hole in the post or scantling to hold the rocker in place and prevent its sliding away.

Construction and Use of the Grizzly

The grizzly is nothing more than a section of sluice-box about 10 ft. long, 1 ft. or more wide and 6 to 8 in. high. On its bottom riffles are set or nailed for the same purpose as in the case of the rocker. The box is set on an incline and the water and dirt are fed at the end courses down the incline, the riffles holding the free gold. The grizzly requires much more water than the rocker, and can be used only where water is fairly abundant. The riffles are made in many ways, but usually are of iron laid across the bottom of the box so as to stop the fine dirt in suspension as it slowly flows down the box. The first used in Canada was the wooden rack-like riffle. This was the only kind used in the Klondike for many years and is yet used on the Stewart. Small poles, an inch or more in diameter, are placed side by side in the box, longitudinally, and are either nailed or fastened in a rack at both ends, as shown. These poles are an inch or less apart, and are 3 to 6 ft. in length. These placed in the bottom of the box answer the purpose of holding the fine dirt, while the coarse and poor dirt flows over and out at the other end. A piece of carpet or heavy blanket is used near the end, and often both riffle and blanket are utilized in combination. Ordinarily the riffle is a piece of wood about 2 in. square, cut in lengths to fit crosswise of the box. They are placed about 6 in. apart. Riffles are, however, made in different shapes but all answer the same purpose.

Sewer Tile of Concrete

By B. B. Hood*

Concrete sewer tile is something that can be made to advantage around a mine or smeltery, especially when it is desirable to keep a skilled mason—or an unskilled one for that matter—busy rather than to lay him off when repair jobs are few. The illustration shows the forms used and two 15-in. concrete sewer tile completed. The tile are 39 in. long, including the 3-in. bell, and are 1½ in. thick, with no reinforcing of any kind. The outside form is made in halves of ¼-in. dressed-pine staves 31½ in. long held in place by two bands of iron screwed to the outside. One of the bands is 7 in. wide and projects 4½ in. beyond one end of the stave form, thereby providing the outside shape for the bell. On the inside of the opposite end is nailed a wood strip ¼ in. thick and 3 in. wide which makes the end of the finished tile 17½ in. outside diameter. The inside form is made of two parts hinged together, which, with a single keying piece makes a cylinder 15 in. diameter by 36 in. long. A taper core of wood, 3 in. thick, with diameters of 18 and 18½ in. completes the set and is used to form the inner part of the bell.

In assembling, the outer forms are placed on boards which make a bottom and are bolted together with six ¼-in. stove bolts. The key is placed in the inner form, being secured by pins through two lugs. This form is placed inside the outer one. For the first tile it was centered at the bottom by dropping three 1¼-in. cubes of wood, between the two forms and about 120 deg. apart. Trouble was caused by these blocks floating out of place when the concrete was put in. This was remedied by putting in three ½-in. setscrews, similarly spaced, near the bottom and through the outer form. As soon as 8 or 10 in. of concrete is in place, there is no danger of

FORMS AND COMPLETED CONCRETE TILE

the center form shifting, so the setscrews are turned back till they are flush with the inside of the form thereby freeing them from the tile. The center form is then filled to the top with concrete and the bell core put in place and filled around.

The concrete is really a mortar, being made of cement and sand tailings, from a concentrating mill, from which the slimes have been washed. Three bags of cement are used to make five tile. The forms are liberally coated with grease to keep the concrete from adhering to the wood and iron. A cheap grade of paper was tried instead of grease, but was not satisfactory.

Five sets of forms complete, cost $64. They were well made, of good material and were as good as new after making 300 ft. of tile. The cost of 210 ft. of these 15-in. tile was, $39 for labor and $30 for supplies, making a total cost of 33c. per running foot, with no allowance for cost of forms. The five forms were filled twice a week. They could be removed after three days, the tile standing where cast for three or four days more to harden. The tile was made indoors and therefore was sheltered from sun and rain while hardening. A week after it was cast it was rolled out-of-doors.

The method of testing one of the tile, eight days after it was cast was as follows: A smooth place was made in the sand and the tile laid upon it. The sand was dug out from under the bell so that little or no weight came upon that part. (Notice that the tile had no side support as it would have had in a culvert.) Full cement sacks were piled upon it, weighing approximately 100 lb. each. The tile broke just after the twenty-seventh bag was in place making the load 900 lb. per linear foot.

*Mining engineer, Chrome, N. J.

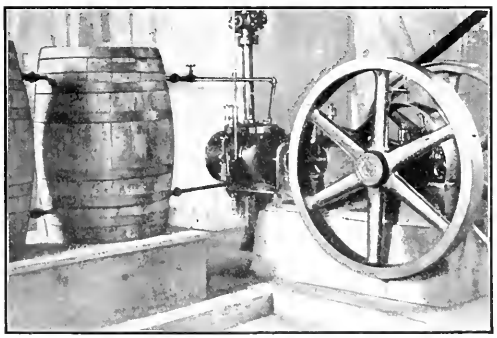
Details of Milling and Smelting

Air-Compressor Cooling With Water Barrels

By Jesse Simmons*

It is not always convenient to erect a tank, or even to secure the necessary water for cooling an air compressor by the usual method of a constantly flowing stream through the water jacket. Especially is this so in underground installations of small compressors to operate one or two hammer drills. It also applies in the desert country.

To overcome the difficulty, many operators arrange for a thermic circulating system of the cooling water by connecting two or more barrels with pipes at tops and bottoms. From the compressor a pipe is run from the bottom of the water jacket to a point near the bottom of the first barrel. From the top of the water jacket a connection is made near the top of the barrel. The accompanying illustration gives an idea of the character of the piping, showing an installation at the Echo Gold Mining Co.'s plant at Maitland, S. D. The compressor



WATER BARRELS FOR COOLING COMPRESSORS

is a single-stage belt-driven Bury machine with 6x8-in. cylinder. The water-jacket connections are made with ½-in. pipe. Between the two barrels—one shown complete and one in part—¾-in. pipe is used. Later a valve was put in the lower connection between the first barrel and the bottom of the jacket. Then by closing the two valves and opening the union on the bottom pipe and petcocks on the water jacket, the water could be readily drained on cold nights. Of course it is necessary at all times to maintain the water in the barrels at a point an inch or so above the top connections. The addition of a bucket or two of water daily replaces that lost by evaporation.

[If the night temperatures do not drop to much below 0° C. it is not necessary to drain off the water, as a little glycerin or alcohol, or some calcium chloride can be added to the water, just as is done in automobile engines.—Editor.]

*Mining engineer, Deadwood, S. D.

Lead Acetate and Zinc Salts in Silver Extraction

By Charles R. Morris*

The experiments described here were made at the Mexican mill, Virginia City, on the effect of lead acetate and zinc salts on the extraction of silver from ores, and also with the idea of finding some method, other than empirical, for the determination of the amount of lead acetate to be used for a given silver ore.

After laboratory tests were made on the ore the extraction appeared to be slightly better when using lead acetate in new solutions, but slightly poorer when using mill solutions. This was attributed to the zinc accumulating in the mill solutions. As the Mexican mill is a continuous-treatment plant, it was decided to run long mill tests with and without lead acetate, keeping all other conditions as nearly the same as possible. The ore was ground so that 92% would pass a 200-mesh screen. The temperature was kept at 95° F., cyanide at 2.5 lb. KCN, and lime at 0.5 lb. CaO. The accompanying table shows averages for each period.

The zinc was determined daily by direct precipitation as sulphide. The reducing power of the solution was also determined. No connection could be found between the extraction and the reducing power. The extraction of silver was 3.2% better in the second test than in the first, the time of treatment was 18% less in the second than in the first, and the consumption of cyanide was ¼ lb. more in the second than in the first.

During test No. 1 we found lead at head of the zinc sump solution by Clennell's method.[1] I believe the

AVERAGE RESULTS OF MILL TESTS

	Test No. 1	Test No. 2
Length of test, days	92	72
Tons per day	72	85.5
Silver, oz., heads	15.88	17.87
Silver, oz., tails	2.22	2.24
Extraction, per cent	84.2	87.4
Acetate, lb. per ton	0.9	nil
Zinc, grams per 100 c.c. solution	0.0848	0.0168
NaCn, lb. per ton of ore	1.875	2.125

accumulation of zinc in the first period was due to the use of lead salts and that the amount of zinc in solution should be kept as low as possible, or rather that there should be only sufficient lead or zinc salt in solution to precipitate the alkaline sulphides. An excess amount of metals in cyanide solution will retard the rate of extraction. As alkaline sulphides will precipitate lead, zinc and silver out of cyanide solution, in the order named, a daily estimation of zinc should be made to determine whether the silver is protected or whether it is in excess.

During 1913 the Mexican company took over a lease on the Monte Cristo mine and I did more work along these same lines. Before starting the mill on this ore, two series of laboratory tests were made—one with freshly prepared solution and the other with mill solution from

*Superintendent, Mexican mill, Virginia City, Nev.

[1]"Engineering and Mining Journal," Sept. 8, 1912.

Mexican ore—varying the proportions of solution to ore and the amount of lead acetate. The tests made with new solution showed that a dilution of 1:10 gave a maximum extraction without lead acetate, while at a dilution of 1:2, which would be more nearly mill-working conditions, the maximum extraction was obtained with $1\frac{1}{2}$ lb. of lead acetate.

Tests made with mill solution at a dilution of 1:10 without the use of lead acetate gave maximum extraction, but slightly lower than that obtained with fresh solution. With a dilution of 1:2 the maximum extraction required $\frac{1}{4}$ lb. of lead acetate. Besides, an excessive amount of lead gave poor extraction in all tests. Judging from this information, the amount of zinc salts in solution appears to have some relation to extraction.

Upon starting the mill on this ore I determined not to add any lead salts until the zinc salts were lower and some marked change of extraction of silver occurred.

Daily tests were made for zinc and for alkaline sulphides by the nitroprussiate test. The results are shown in the accompanying table.

MILL TESTS ON MONTE CRISTO ORE

*The tails for a given day are for heads three or four days previous.

The table gives the silver content for heads and tails, the amount of lead used and the amount of zinc in solutions returning to the head of the gold tanks.

In testing for alkaline sulphides we were unable to detect any, but from the cleanup made during the period when no zinc was in solution matte was formed on our bars. This was the only time we had matte. I believe that alkaline sulphides must have been in solution at that time. During the period we had trouble in titrating with silver nitrate. After first adding silver, a dark brown precipitate would form, which would disappear on shaking, and the final precipitate would be dark.

Complex cyanide solutions were made in the laboratory to test for alkaline sulphides by the nitroprussiate method. It was found that cyanide solutions containing small quantities of sulphide would react with nitroprussiate only in absence of silver or zinc salts.

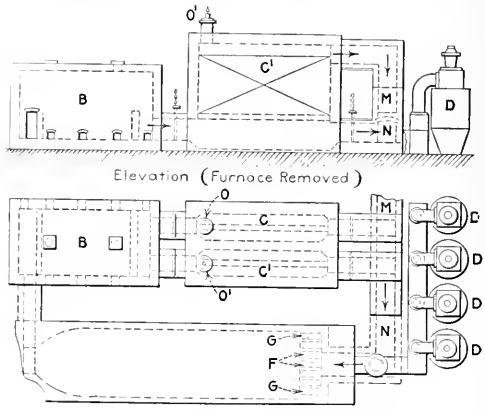
New Method for the Preparation of Copper Sulphate

A new method for the technical preparation of copper sulphate has been proposed by T. Fabiola, according to the *Journal of the Society of Chemical Industry*, in the issue of Apr. 30, 1915. A hot mixture of sulphur dioxide and air—that is, the gas from sulphur or pyrites burners—is passed upward through a glass tower surrounded by a hot-air jacket and packed with copper turnings or shot. Nitric acid, or nitrous gases, are introduced at the upper end of the tower. Copper sulphate free from nitrate has been obtained in this way in laboratory experiments, and it is suggested that towers packed with copper might be used in place of Glover towers in the manufacture of sulphuric acid by the chamber process.

Perkins Gas-Fired Reverberatory Furnace

Walter G. Perkins, of London, has been granted a patent (U. S. pat. 1,136,834) for a gas-fired reverberatory furnace, the gases from which pass through an enlarged dust chamber and then into a checker-work regenerator having two chambers which are worked alternately. The construction is, in effect a non-reversible gas-fired regenerative reverberatory furnace.

The accompanying drawing shows a typical plant. The gas producers *D* are placed as near the furnace as practicable, and the gas flows through the collecting flue to the gas ports *F* of the furnace. Issuing from these the gas meets the heated secondary air from the ports *G*,



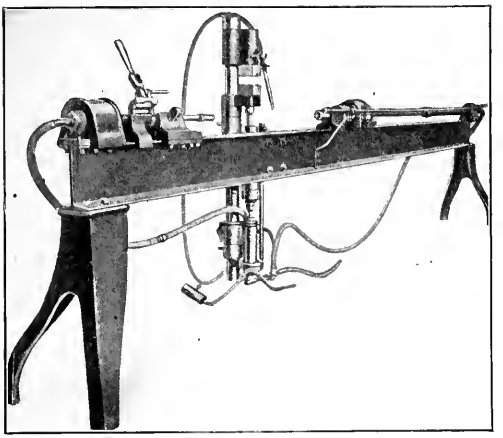
NONREVERSIBLE GAS-FIRED REVERBERATORY FURNACE

which has come from the regenerator. The waste gases from the reverberatory pass to the dust chamber *B* upward through the generator and thence to the chimney through the flue *M*. The regenerator chambers *C* and *C*¹ are constructed in the usual manner with checker-work and are used alternately. On top of each regenerator chamber is an air-admission valve *O* and *O*¹ permitting the air to flow downwardly through the regenerator chamber into the secondary-air flue *N*, and thence to the reverberatory furnace. It is expected that the passages of the regenerator will be kept clear of dust which may be carried along with the gases by providing an updraft of such gases through the regenerator and a downdraft when the chamber is used for secondary air. The use of reversible regenerative furnaces for copper smelting proved unsatisfactory in the past largely on account of dust troubles in the regenerator which the inventor claims to have obviated in the present design.

Mining & Metallurgical Machinery

The Wonder Drill Sharpener

A new drill sharpener of unusual type is being put on the market by the Hardsoog Wonder Drill Co., of Ottumwa, Iowa. This machine, although suitable for sharpening any style of hammer-drill steel, is very light, weighing only 1200 lb., and consists of the usual two elements,



WONDER DRILL SHARPENER

one horizontal and one vertical, for upsetting the drills and forming the wings. Both of these elements are mounted on an I-beam, which constitutes the main frame of the machine, which is supported on two pair of legs like an engine lathe.

This machine is claimed to have all of the advantages of any machine sharpener plus the additional advantage that it requires only 40 ft. of air for its operation and weighing very much less its cost is smaller.

Armored Wire Rope

Armored wire rope, Gore construction, is claimed to have a wearing life two or three times greater than similar quality rope of standard construction. In this rope each strand is wound with flat steel wire having convex edges, and forms a protective armor that prevents all exterior abrasive wear on the tensile-strength wires. The flat armoring wires are held transversely to the axis of the rope so that they do not affect its flexibility, and the convex edges of the armoring wire permit the flexing of the rope without any creeping of the armor. This rope is marketed by the Waterbury Co. of 80 South St., New York, as Waterbury armored wire rope, Gore patent. The standard constructions are composed of 6 strands, 19 wires to the strand; 6 strands, 37 wires to each strand; or 6 strands, 61 wires to each strand. The rope may have a hemp or wire center, as conditions demand.

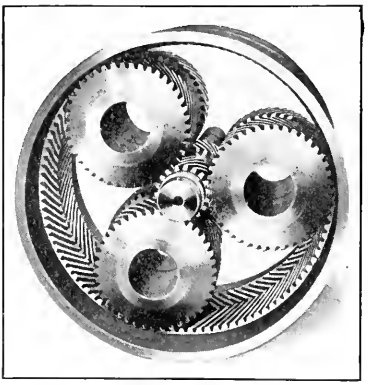
The Waterbury armored rope has been applied to steam-shovel service, dragline excavators, harbor and gold dredges, etc. El Oro Dredging Co., of California, tested some of the Waterbury armored rope in competition with ordinary wire rope and has written the manufacturers as follows:

> We used as a side line on a larger dredge 650 ft. of ⅞-in. high-grade rope from one of the large manufacturers, which cost $123.22, and lasted 183 days. We replaced this with 650 ft. of ¾-in. crucible-steel, Gore construction, steel-clad rope furnished by you at a cost of $82.56. To make the units of service the same for each dollar of cost, your rope should have given us 122 days' service, but at this writing it has been in service 254 days, and we have no present intention of taking it out. In other words, it has already given us twice the service of the other rope for each dollar of cost, and we are not through with it.

The Waterbury Co. also markets a fibre-covered wire rope under the name of Waterbury Fibreclad wire rope. The tarred marline covering protects the wire strands of the rope from moisture and grit, and unlike manila rope is not affected by changes in atmospheric conditions. Hence it neither stretches nor swells and jams in the blocks. It is claimed that it will outwear either bare wire or manila rope. Its strength is said to be greater than that of manila rope of the same size and the weight is 50% less than that of manila rope of the same strength.

Planetary Reduction Gear

The planetary type of gear shown is a recent development of the Turbo-Gear Co., Baltimore, Md. It is designed to be used as a speed-reducing or speed-increasing



TURBO-REDUCTION GEAR

gear and will run either right- or left-hand. The driving and driven shafts rotate in the same direction.

The gear consists of a large internal double-helical gear made of an openhearth steel forging. A double-helical pinion cut integral with the high-speed shaft is made of chrome-vanadium steel. The intermediate double-helical gears are made of manganese-bronze and are

mounted on hardened and ground forged-steel shafts, secured to the slow-speed member.

The slow-speed member, to which is secured the slow-speed shaft, is mounted on two heavy-duty ball bearings, one on each side of the gears, and is supported directly by the heavy housing. Thus, it will be seen that the slow-speed member and the shaft carrying the intermediate gears and the high-speed shaft and pinion are independent of each other for support.

Schoop Metal-Spraying Pistol

In the *Journal* of Mar. 11, 1911, there is a description of an early form of apparatus for mechanically applying a thin coat of metal, the device being known as the Schoop metal-spraying pistol. By its use it is possible to apply a metal coating to other metal surfaces and to many other substances, such as wood, plaster, paper, leather, glass, porcelain and cloth. An important feature, also, is the variety of metals and alloys that can be so applied. The coating may be thick or thin, as desired, and is applicable not only to fine decorative construction, but also for rough work, as coating iron or steel articles with some noncorrosive covering such as lead, zinc, tin or copper.

In a paper read by R. K. Morcom before the Institute of Metals the Schoop process is described as follows:

"The essential parts of the machine, or 'pistol' as it is called, are a combined melting and spraying jet and a feed mechanism. The metal, in the form of rod or wire, is fed to the melting flame. The flame can be formed by coal gas, water gas, acetylene, hydrogen, etc., burning in air or oxygen, according to the metal used. The gases are supplied at such pressures as to prevent blowing out and to insure a highly reducing flame. The spraying jet can be of carbon dioxide, nitrogen, air, steam, etc., the pressure used being necessarily high enough to produce an adhesive coating. To obtain the best adhesion, the surface on which the metal is sprayed must be absolutely clean and of an open nature to give a key for the deposit. Sand-blasting with sharp sand has been found best. Shot give too polished a surface. Such surfaces as fabrics, wood, unglazed earthenware and asbestos require only freedom from grease, as their surfaces give a natural key.

"As at present constructed, the standard pistol uses about 0.55 to 0.6 cu.ft. of air per min. for every 1 lb. per sq.in. air pressure, so that with an air supply at 80 lb. per sq.in., which is a very suitable figure for ordinary spraying, the air consumption will be from 45 to 50 cu.ft. per min. The mass of this will be from 830 to 920 grams, and the mass of metal sprayed by this air will be from about 8 grams in the case of iron to about 200 grams in the case of lead.

"The action of deposition is probably a complex one. The minute particles of solid metal are driven with such force against the object that in some cases they fuse, but, owing to their small relative size, are promptly chilled by the object to which they adhere. If any of the particles are molten or gaseous they will adhere. In addition, the suddenly chilled particles are possibly, or even probably, in the state of unstable equilibrium found in 'Prince Rupert's drops,' and act like so many minute bombs, bursting on impact to almost molecular dimensions.

"The process requires some care in manipulation, as by varying the conditions it is possible to spray porous or nonporous coatings, and with some metals anything from a pure metal to a pure oxide. With care, however, nonporous, oxide-free, adherent coatings can be produced of almost any metal on almost any solid. In addition to metals it is possible to spray fusible nonmetals, or, by stranded wires, alloys of metals or mixture of metals with nonmetals."

The spraying pistol and process are the invention of a Swiss named M. U. Schoop, and while it has been in use in Europe for some time, it has been introduced into the United States only within the last 18 months. The pistol is a portable hand tool weighing about 3½ lb., and is connected by small tubes with reservoirs supplying oxygen, hydrogen and compressed air. The compressed air-blast nozzle is concentric with the oxyhydrogen burner. As the compressed air issues from the pistol it drives a minute turbine, which in turn propels friction wheels that feed the wire into the flame.

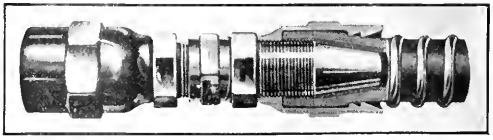
In at least one instance the apparatus is employed in the mining field. Phelps, Dodge & Co. use it at Douglas, Ariz. The purpose for which it is there operated is best described by Lawrence Addicks, formerly of that company, who says under date of Feb. 6, 1915:

"I have been experimenting with several processes for lead-coating materials of construction to protect them from acid liquors. One particular problem has been the coating of the copper connections attached to carbon anodes in the electrolysis of copper in a sulphate electrolyte. The ferric sulphate formed gradually eats away unprotected copper, and it is difficult to devise an all-lead connection.

"A Schoop pistol, furnished by the Metals Coating Co. of America, People's Gas Building, Chicago, Ill., has made coatings of a satisfactory appearance. They have not as yet been tested for durability in service. Our method of anode construction is to electroplate the upper ends of the carbon plates with copper, then to attach the copper terminal strips with copper bolts; next to apply a coat of acid-proof paint; finally to spray a substantial coating of pure lead over the paint."

"National" Hose Coupling

The "National" hose coupling embodies durability and efficiency in attaching a hose to a threaded metal terminal. The principle of the device is distinctive, since it makes no attempt to apply pressure to the outside of the hose,



"NATIONAL" HOSE-COUPLING DEVICE

the whole force being applied from the inside, making it easy to obtain a tight connection.

It is particularly adapted to compressed-air connections on drills, pneumatic tools, and to similar uses. It is made by the National Hose Coupling Co., People's Gas Building, Chicago.

What the Dip Needle Can and Cannot Do

By C. A. Cheney, Jr.*

SYNOPSIS—A series of questions and answers covering the conclusions to be deduced from dip-needle indications. Experience is required both in observing and reasoning. It is not reliable in the hands of the amateur.

In the course of a long experience I have met many so-called "practical" mining men who have expressed themselves as having little faith in the results of magnetic surveys made for the purpose of delimiting iron formation. One went so far as to remark that an old steam gage would indicate the position of an iron-bearing formation as well as would a dip needle.

At the other extreme there are many who are able, from a dip-needle survey, to make marvelous deductions as to the depth of burial, quality of ore, size of orebody and attitude of the strata of the formation. These persons visualize the iron formation as made up of inclined strata with beautifully regular dips and curves, and if necessary, they often unconsciously obtain needle readings which will agree with a preconceived theory as to the attitude of the underlying formation.

Its Value in Iron-Ore Exploration

Between these two extremes are a small number of men who have had the opportunity of following exploration work from prospect to mine and are therefore able to recognize the extent to which it is wise to draw inferences from a magnetic survey. The dip needle is now in greater use than ever before and is invaluable in many ways, but its real limitations are little known. For this reason, answers to some oft-repeated questions are of interest to those engaged in exploration for iron ore.

Do the dip-needle readings furnish any clew as to the depth of burial of the formation?

Observation leads me to assert that in any district in the Lake Superior region the readings do not indicate, even in a most general way, the distance of the formation below the surface. It follows that the differences of elevation in any district probably are not great enough to cause any relative variations in the amount of magnetic dip. As evidence I can cite the following cases: A maximum magnetic dip of 10° on a Vermilion Range outcrop of iron formation; a maximum magnetic dip of 40° on a possible southwestern extension of the Vermilion Range at a point where drilling subsequently proved the depth of surface to be 450 ft. In another district the maximum reading was 35° at a point where geological considerations indicate that the formation causing the magnetic dip is at least 1200 ft. below the surface. In this same district maximum magnetic readings actually grow less with decrease in thickness of overburden.

Enough other cases might be cited to prove conclusively that in any Lake Superior district the relative variations in the amount of magnetic dip are not indicative of variations in depth of overburden. In instances where geologists have considered the dying out of the magnetic indications as indicative of an increasing depth of overburden, the real reasons are, probably, that the iron formation has "petered out" or if present that it was originally less metamorphosed than the adjoining portion and consequently is so thoroughly altered to the nonmagnetic oxides as to cause no variations of the magnetic needle.

Quality of Ore Not Determinable

Do the magnetic readings furnish any evidence as to the quality of the ore?

In only two mines in the Lake Superior region is magnetite mined as a magnetic ore. Practically all of the ore produced in the region is composed of hematite, limonite and other nonmagnetic oxides.

The magnetic field encountered in crossing most iron formations is therefore ordinarily not caused by the ore, but by the associated magnetic slates, which may be the hanging wall, foot wall or bottom of an orebody, or may not be associated with any ore. There may be enough disseminated magnetite in some ores to influence slightly the needle, but where magnetic slates are present the relative amount of this pull would be very small.

The almost completely altered and productive formation of the central Mesabi district exerts but a small pull on the magnetic needle, but in an adjoining district a similar small magnetic attraction is frequently found to be due to a little-altered and unproductive formation. On the other hand, high magnetic readings of equal value have frequently been found, caused in one case by a richly productive iron formation and in another case by an absolutely barren iron formation.

From these considerations it is evident that it is unwise to estimate the probable quality of the ore by means of the dip-needle readings.

Do the readings indicate the size of the orebodies?

No, for reasons that have already been enumerated. In practically all cases, however, the area of the magnetic field is directly proportional to the area of a horizontal plane passing through the top of the iron formation. That is, a wide area of magnetic attraction is representative of a wide area of iron formation, and vice versa. Examples are so plentiful that this fact is universally recognized.

Maximum Magnetic Line

Does the maximum magnetic line overlie the iron formation?

Most exploration work is conducted on the theory that the maximum magnetic line overlies the iron formation. In general it does, but frequently it does not. There are numerous cases where the maximum magnetic line sometimes lies completely outside of the boundary of the iron formation as projected vertically to the surface.

*Geologist, Madison, Wis.

On the Cuyuna range the distance of the maximum magnetic line outside the vertically projected boundary of the iron formation is in some cases over 100 ft. Furthermore, in the same district the maximum magnetic line occasionally crosses the strike of the iron formation at small angles. Because of these conditions, in that district at least, the drilling should not be confined too closely to the locus of the maximum magnetic readings. It has been common practice to do this and as a result some properties have been condemned before all exploration possibilities have been exhausted.

Character of Magnetic Readings Differs with Sedimentary and Igneous Rock

Does the character of the magnetic readings indicate whether the attraction is caused by a sedimentary iron formation or by a basic igneous rock?

In general, yes. One who has done much work with the dip needle can usually recognize the freakish character of the magnetic dips caused by other material than the type iron formation.

My experience has been that massive basic segregations in igneous rocks almost invariably attract the south end of the needle, whereas the sedimentary iron formations attract the north end. Sometimes these magnetic areas are in many respects similar to magnetic areas caused by a sedimentary iron formation, the difference being that a different end of the needle is attracted in one case or the other.

Negative readings—attraction of south end of needle—are also obtained in many cases along formation boundaries, usually the contact of a slate and an igneous rock.

In some instances positive readings are due to the presence of magnetite in greenstone schists. These dips may be recognized by their erratic character. The maximum readings in general are not related on adjacent cross-sections and die out rapidly in a transverse direction.

Is it possible to determine the dip of the formation from the magnetic readings?

Deductions derived from dip-needle readings as to the attitude of the formation seldom "pan out" right, and when they do it is probably largely a case of coincidence. Where the variations of magnetic dip are uniformly similar on several cross-sections and where the differences in variation of magnetic dip are marked, they may give a real clew as to the dip of the formation. Any theories based on small variations are, however, very apt to be exploded when the formation becomes known by drilling.

In spite of the limitations of the dip needle, I doubt if any other invention has made or saved so much money in proportion to its cost, for men engaged in search of iron formation. It is an undeniable fact that an iron formation can be located and traced by means of a dip needle, and this is always the prime reason for such a survey.

Furthermore, the knack of taking correct dip-needle readings can only be obtained by much experience with the little instrument in several districts. The work looks extremely simple and I have heard many say, "There's nothing to it, I can do it," but these persons are in the same class with those who think that they can "guess which shell the little pea is under."

Bureau of Mines Radium Production

The production of radium from Colorado carnotite ores by the Bureau of Mines, in connection with the National Radium Institute, has passed the experimental stage in its new process and is now on a successful manufacturing basis, according to an announcement made on July 27 by Secretary of the Interior Franklin K. Lane. He also declared that the statements made to Congress concerning the ability of the Bureau of Mines to produce radium at a greatly decreased cost over that of other processes had been substantiated.

The cost of one gram of radium metal produced in the form of bromide during March, April and May of the present year was $36,050. The cost of producing radium in the small experimental plant during the first few months of the Bureau's activities was somewhat higher, but not enough to affect seriously the final average.

It should not be inferred, however, that this low cost of production necessarily means an immediate drop in the selling price of radium. The National Radium Institute was fortunate in securing through the Crucible Steel Co. the right to mine on 10 claims of carnotite ores belonging to it, and this was practically the only ore available at the time. Since then new deposits have been opened, but these are closely held; and according to the best judgment of the experts employed by the Bureau of Mines, the Colorado and Utah fields, which are much richer in radium ores than any others known, will supply ore for a few years only at the rate of production that obtained when the European war closed foreign mines. The demand for radium will also increase rapidly.

The 10 carnotite claims being operated at Long Park, Colo., by the National Radium Institute have already produced more than 796 tons of ore averaging over 2% U_3O_8. The cost of ore delivered at the radium plant in Denver has averaged $81.30 per ton. This included 15% royalty, salary of the Bureau of Mines employees, amortization of camp and equipment and all expenses incident to the mining, transportation, grinding and sampling of the ore.

A concentrating plant for low-grade ores has been erected at the mines and is successfully recovering material formerly wasted. The radium plant at Denver has now a capacity of three tons of ore per day, having been more than doubled in size since last February. Before that time the plant had been run more or less on an experimental scale, although regularly producing radium since June, 1914. To July 1, 1915, slightly over 3 grams of radium metal were obtained in the form of radium-barium sulphate containing over 1 mg. of Ra per kg. of sulphates. The conversion of the sulphates into chlorides and the purification of the radium therefrom are easily accomplished, and with small loss of material. Unfortunately, however, acid-proof enamel ware, obtainable only in France, has not been delivered of sufficient capacity to handle the crystallization of the full plant production, so that only 1304 mg. of radium have been delivered to the two hospitals connected with the National Radium Institute. The remaining radium can be crystallized at any time from neutral solution in apparatus already installed. But the greater rapidity and efficiency of production of this valuable material by the methods

used have decided the Bureau of Mines to await the completion of apparatus now being built before pushing the chloride crystallization to full capacity.

The average radium extraction of all ore mined by the National Radium Institute has been more than 85% of the amount present in the ore, and for the last five carloads of carnotite treated, above 90%.

※

War Affects the Manganese Industry

The production of manganese ores in the United States in 1914 amounted to 2635 long tons, which was 1413 tons less than the output of 1913, according to the Geological Survey. The manganese ore shipped in 1914 was derived from mines in Virginia, South Carolina and California. The domestic output was small compared with the imports of manganese ores, which amounted in 1913 to 345,090 long tons and in 1914 to 283,294 long tons.

India, Russia and Brazil have been the principal countries from which manganese ore has been imported. In 1913 the largest imports were from India, amounting to 141,587 tons, and the imports from Russia were 124,337 tons. The closing of the Dardanelles, and probably the scarcity of vessels for transportation from India in 1914, had the effect of reducing the imports from Russia to 52,681 tons and those from India to 103,583 tons. These decreases were partly compensated for by the increased shipments from Brazil, which were 70,200 tons in 1913 and 113,924 tons in 1914.

The output of all grades of manganiferous ores in 1914 was 445,827 long tons (mainly from the Lake Superior region), of which 60,414 tons contained more than 15% of manganese and was used in the manufacture of low-grade ferromanganese and manganiferous pig iron.

The marketed domestic production of ferromanganese in 1914 was 100,731 long tons and the imports of ferromanganese were 82,997 long tons. The marketed domestic production of spiegeleisen decreased from 106,980 long tons in 1913 to 76,625 tons in 1914, and the imports increased from 77 tons in 1913 to 2870 tons in 1914. The larger part of the spiegeleisen was made from manganiferous zinc residuum derived from New Jersey mixed manganese and zinc ores, though for the first time since 1909 spiegeleisen was produced from the manganiferous ores of Leadville.

As heretofore, practically all the domestic output of ferromanganese was made from imported ores, though some medium-grade ferromanganese was made from manganiferous iron ores of the Cuyuna Range in Minnesota at the Dunbar furnace in Pennsylvania.

If the domestic production of steel and steel products increases considerably on account of the temporary elimination of competition from European steel products, the sources of manganese supply may be abnormally taxed to meet the demand. The increased price, however, will stimulate domestic production and permit the mining of manganese ores which, under normal conditions, could not be profitably worked.

[The situation at the present time has aroused interest in the manganese ores of Virginia, and several of the deposits in the southwestern part of that state are being investigated.—Editor.]

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALUMINUM ALLOY. William A. McAdams, Bay Shore, N. Y. (U. S. No. 1,146,185; July 13, 1915.)

BRIQUETS—Binding Means for Briquets. Wilhelm Schumacher, Osnabrück, Germany. (U. S. No. 1,146,455; July 13, 1915.)

CONCENTRATOR—Ore Concentrator. Fritz Oscar Stromborg, Salt Lake City, Utah. (U. S. No. 1,146,211; July 13, 1915.)

CRUSHER. Thomas L. Smith, Milwaukee, Wis. (U. S. No. 1,145,929; July 13, 1915.)

CRUSHERS—Lubricating Device for Gyratory Crushers. Richard Bernhard and Jacob M. Sholl, Milwaukee, Wis., assignors to Power & Mining Machinery Co. (U. S. No. 1,145,967; July 13, 1915.)

DRILLING—Air and Water Blowpipe for Rock Drilling. Frank T. Sanders, Colorado Springs, Colo., assignor of one-half to Owen Dodge, Colorado Springs, Colo. (U. S. No. 1,146,284; July 13, 1915.)

DRILLS—Feeding Means of Percussive Rock-Drills, Coal-Cutters, and the Like. Frank Simon and John William Scott, Minnaar, Transvaal, South Africa. (U. S. No. 1,146,356; July 13, 1915.)

EXTRACTION—Composition and Process for Extracting Precious Metals from their Ores. James F. Williams, San Francisco, Calif. (U. S. No. 1,145,954; July 13, 1915.)

FILTERING APPARATUS. William E. Holderman, Salt Lake City. (U. S. No. 1,146,256; July 13, 1915.)

FLOTATION—Concentration of Minerals by Flotation. Archibald R. Livingston, Cañon City, Colo., assignor to the New Jersey Zinc Co., New York, N. Y. (U. S. No. 1,147,633; July 20, 1915.)

GRAPHITE—Process for Converting Coke into Graphite. H. Plauson. St. Petersburg, Russia. (Brit. No. 17,732 of 1913.)

PHOSPHATE—Fertilizer Composition and Process of Making It. Thomas Leopold Willson and Maximilian Matheus Haff, Ottawa, Ont., Canada, assignors, by direct and mesne assignments, to Southern Investment Co. of Canada, Ltd., Montreal, Canada. (U. S. No. 1,145,107; July 6, 1915.)

PIG IRON—Process for Dephosphorizing Pig Iron. Amand Francois Pasquier, Dijon, France. (U. S. No. 1,145,506; July 6, 1915.)

POTASH—Process of Making Potash and Structural Materials and Products Thereof. Arthur C. Spencer, Washington, D. C. (U. S. No. 1,146,532; July 13, 1915.)

PUMPS—Balancing Means for Centrifugal Pumps. Ferdinand W. Krogh, San Francisco, Calif. (U. S. No. 1,146,078; July 13, 1915.)

REHEATING FURNACES—Improvements in or Relating to Reheating Furnaces. Eickworth & Sturm Ges. mit Beschrankter Haftung, Dortmund, Germany. (Brit. No. 5875 of 1915.)

ROASTING—Ore-Roasting Furnace. Irven R. Margetts and Earl R. Pembroke, Salt Lake City, Utah. (U. S. No. 1,145,329; July 6, 1915.)

SCREEN or Separator. Thomas Joseph Sturtevant, Wellesley, Mass., assignor to Sturtevant Mill Co. (U. S. No. 1,141,988; June 8, 1915.)

SEPARATOR—Magnetic Separator. Francis B. Dutton and Benjamin E. McKechnie, Lebanon, Penn., assignors to Pennsylvania Steel Co., Philadelphia, Penn. (U. S. No. 1,146,141; July 13, 1915.)

SIEMENS-MARTIN FURNACES—Improvements in or Relating to Siemens-Martin Furnaces. Eickworth & Sturm Ges. mit Beschrankter Haftung, Dortmund, Germany. (Brit. No. 5651 of 1914.)

SKIMMING LADLE. Jesse L. Jones, Wilkinsburg, Penn., assignor to George L. Curtiss Co., Pittsburgh, Penn. (U. S. No. 1,145,422; July 6, 1915.)

SLAG STEAM GENERATOR. Leonce L. Battu, New York, N. Y., assignor to Slag Steam Generator Co., New York, N. Y. (U. S. No. 1,145,178; July 6, 1915.)

SMELTING FURNACE. Pierre Plantinga, Cleveland, Ohio. (U. S. No. 1,146,097; July 13, 1915.)

SMELTING FURNACES—Reversing Valve of Gas-Fired Smelting Furnaces and the Like. Evan Lewis, Swansea, Wales. (U. S. No. 1,146,582; July 13, 1915.)

SMOKE—Cooler-Flue and Hopper for Fume-Arresting Apparatus. Alfred U. Field, Redding, Calif. (U. S. No. 1,146,319; July 13, 1915.)

SULPHUR SMOKE—Recovery of Sulphur Dioxide. James B. Garner, Pittsburgh, Penn., assignor to Metals Research Co., New York, N. Y. (U. S. No. 1,145,579; July 6, 1915.)

SULPHURIC ACID—An Improved Apparatus for Concentrating Sulphuric or Other Acids. P. L. Pfannenschmidt, Thornhill, Leeds, and Richard Moss, Dewsbury, Eng. (Brit. No. 13,642 of 1914.)

TUBE MILL. Guy C. Howard, Everett, Wash. (U. S. No. 1,146,760; July 13, 1915.)

TUNNELING MACHINE. Dighton A. Robinson, Seattle, Wash. (U. S. No. 1,146,281; July 13, 1915.)

ZINC—Process of Treating Zinc-Bearing Materials. Woolsey McA. Johnson, Hartford, Conn., assignor to Continuous Zinc Furnace Co., Hartford, Conn. (U. S. No. 1,146,075; July 13, 1915.)

ZINC—Process for the Treatment of Zinkiferous Materials. H. Specketer, Griesheim-on-the-Main, Germany. (Brit. No. 20,039 of 1913.)

SEOUL MINING CO'S PROPERTY, HOLKOL, CHOSEN

In the upper view is shown the rapidly advancing mill construction with much of the machinery on the ground. In the lower view, taken from above the Tul Mi Chung millsite, is shown the mill under construction and a portion of the surrounding country.

Editorials

The Birth of a Myth

Those who want to take the trouble may witness the development of a myth from its beginning. This is the belief, already held more or less extensively in Great Britain and Canada, that the American zinc-smelting industry is controlled by Germans, that they boosted the price for spelter to four or five times the normal in order to penalize their enemies and thus carry on warfare in one way if they could not in another. Nothing could be any more ridiculous or contrary to patent facts, yet without any doubt this myth will live and grow. Merely for the sake of the accuracy of the records, however, it is worth while to state the facts. Here they are: The zinc smelters of the United States, together with the number of their retorts, are listed annually. Their relative importance and their producing capacity are about in proportion to the number of their retorts. On Jan. 1, 1915, the total number of retorts in American zinc-smelting works was about 120,000. The firm of Beer, Sondheimer & Co., of Frankfurt-am-Main, has a New York agency, and is interested in the National Zinc Co., which possesses two smelteries with an aggregate of about 7500 retorts. The American Metal Co. is an American corporation, whereof numerous of its important officers are American born, but it is no doubt affiliated with the Metallgesellschaft, of Frankfurt-am-Main. The American Metal Co. owns and controls the Bartlesville Zinc Co., the Lanyon Starr Spelter Co., and the American Zinc & Chemical Co., which possess four smelteries with an aggregate of about 17,500 retorts. Consequently, these interests at the beginning of this year had an aggregate of about 25,000 retorts, a trifle more than 20% of the American total.

We are not intimating that these concerns, either of them or both of them, ever had any idea of playing tricks upon the buyers for the Allies, but are stating the plain fact that the control of the zinc-smelting industry has never been centered in any one quarter. It always has been, and still is, divided among a good many independent interests. The other big interests in the business are: The American Zinc, Lead & Smelting Co. (of Boston), the Edgar Zinc Co. (U. S. Steel Corporation), the Granby Mining & Smelting Co. (of St. Louis), the Grasselli Chemical Co. (of Cleveland), the Hegeler Zinc Co., Illinois Zinc Co., and Matthiessen & Hegeler Zinc Co. (of Illinois), the New Jersey Zinc Co. (of New York), and the United States Zinc Co. (a subsidiary of the American Smelting & Refining Co.). Recently, the United States Smelting, Refining & Mining Co. (of Boston) bought three old works and entered the business. The pedigrees of these concerns are so well known that no restatement of them is necessary.

The British must look nearer home to find out why the price for spelter was rushed upward so extravagantly. They will find a large part of the explanation in their own policy of "muddling along." Among other exhibitions of the muddling that may be mentioned are the unnecessary refinement in the spelter specifications and the farming out of ammunition contracts in ways that caused buyers in the same ultimate interest to appear as competitors of each other and to figure as being in the market for a great deal more spelter than was really the case. As an exhibition of ignorance, muddled with stupidity, the buying of spelter during the second quarter of 1915 was preëminent; nor does any great light appear yet to have burst through the shells inclosing the official minds.

The Recession in Copper

There is now a good deal of talk in the newspapers about the greatly increased production of copper, the greatly diminished exportation as compared with corresponding periods of 1914, and the recession in the price of the metal. In the absence of any statistics the trade is now in the dark respecting the actual rate of production. However, there is no doubt that the present production is very large, perhaps the largest on record so far as the United States is concerned, inasmuch as all of the important mines are being operated as strenuously as can be done. Nor is there any doubt that the exportation of refined copper in bars, cakes and ingots is less than it used to be, for there are definite statistics upon that subject. However, those statistics do not give the quantity of copper exported in the form of brass and other manufactures, which exportation has lately increased enormously. It is well known that the brass makers of Connecticut are working overtime.

With respect to the recession in price, the previous exaggeration of the Wall Street papers is now coming home to roost. The copper market did not at any time rise to 20½c. The high point was 20¼c., regular terms, which corresponds to a trifle more than 20c. cash, New York, the customary discount of ½ per cent. amounting to 10 points, while the average freight rate on deliveries is probably in the neighborhood of 10 points, making a total of 20 points. Some sellers reckon the average cost of delivery a little lower, while others reckon the total differential a little higher, there being usually a loss of interest of about 15 days in addition to the regular allowance of 30 days. Therefore the price of copper has declined from the level of about 20c., not 20½c.

The decline started immediately after the cessation of the great buying movement about the middle of June. The principal producers were then sold well ahead, and, being busy with their deliveries, they were more or less indifferent as to whether buyers wanted to contract immediately for more copper or not. On the other hand, there are interests that contractually have to take in copper all the time and must either accumulate it at the expense of capital or credit, or must sell it for what they can get. There are numerous small producers of crude copper who are confronted by the same conditions. The

recent recession in the price for copper has come about naturally through the efforts of such interests to find a level upon which the metal would move. There has been no pressure on the market and the inauguration of a new buying movement of important dimensions would no doubt lead to a sharp rally.

Indeed the situation of copper appears to be fundamentally strong. In spite of the increased production, the refiners agree that the stocks in their hands have not increased. The consumption of copper for ammunition will continue to be large, but most important is probably the coming increase in domestic, peaceful, consumption which the revival in the iron and steel industry—now a well-established fact—is believed to foreshadow.

⁂

Tin Smelting in the United States

According to British reports, a well-known metallurgical corporation—Williams, Harvey & Co., Ltd., of Bootle—has informed its Bolivian clients by circular that it is establishing a modern tin-smelting works on an appropriate site in the United States for dealing with Bolvian *barrilla*. Other reports have associated this statement with the plan of the American Smelting & Refining Co., previously announced. We are authorized by a high officer of the latter company to state that its tin-smelting enterprise is in all respects an independent one. We have been unable to learn definitely respecting the plans of Williams, Harvey & Co.

The American Smelting & Refining Co. is making excellent progress with its plant near Perth Amboy. It expects to be able to begin the refining of tin before the end of the fall, and it hopes that the whole of the plant will be in operation by the middle of the winter.

⁂

The Directorship of the Bureau of Mines

A matter of great concern to the mining industry is the appointment of a director for the Bureau of Mines in succession to Dr. Holmes. A good man in that important position can be very helpful to the mining industry; a bad man can be very harmful; a mediocre man may be neither the one nor the other, but may be simply the holder of a job. According to all accounts, the job-hunters are already out in great force, and also there are prevalent some queer ideas as to what constitutes the proper qualifications for a director of the Bureau of Mines.

A Washington paper that has come to our attention tells of some conference that occurred in Philadelphia, and concluded its story with this paragraph:

> Among other names discussed at the conference either with the indorsement of one or more of the conferees or presented at the suggestion of friends were: Sheriff A. Lincoln Acker, E. T. Stotesbury, Charlemagne Tower, Justice Robert Von Moschisker of the Supreme Court, Common Pleas Judges Charles Y. Audenried and J. Willis Martin; William T. Tilden, former president of the Union League; Louis J. Kolb, Attorney-General Francis Shunk Brown and Assistant District Attorney William Findlay Brown.

No, readers in the mining districts, East and West, we do not think that this was intended as a joke. In the minds of many persons a sheriff of a county, or an assistant district attorney, would be just as competent as the director of the Bureau of Mines as any mining engineer, mine operator, or mining scientist. Nor is it a humorous suggestion that the appointment may fall to some mining walking-delegate. In the appointment of the directors of the Census and of the Mint the experts were passed by, and we must make up our minds to the chance that the same disagreeable thing may happen with respect to the directorship of the Bureau of Mines.

It is the hope of the *Journal* that the President will appoint to this important position a man of high professional attainments and great distinction in the mining industry. We pray that the President will thus limit his choice.

⁂

A Reported Steel Combination

A Cleveland correspondent, apparently of an imaginative turn, last week sent out a dispatch announcing the preliminary organization of a new combination to rival the Steel Corporation. According to his statement the new concern was to include the Bethlehem, the Jones & Laughlin, the Cambria, the Pennsylvania, the Lackawanna Steel companies and the Colorado Fuel & Iron Co., together with several minor companies and probably the Republic Iron & Steel Co. In brief, it was to include all the prominent independent steel makers and as many of the smaller concerns as one might care to mention. The new combination was to be headed by Charles M. Schwab as manager and Henry C. Frick as financier.

The publication of the statement was met by a chorus of denials from all the parties concerned. It is claimed that, so far from such a combination being partly organized, it was not even contemplated or considered by the parties chiefly in interest; and that the larger independent concerns had no idea of giving up their individuality or of becoming members of a new combine. So far as can be judged these denials are sincere, and no one now has it seriously in mind to organize a new combination.

Somewhat similar rumors have been circulated before, but the formation of new combinations would hardly be considered while the Government suit to dissolve the Steel Corporation was pending. The recent decision in that suit might be thought to open the way for further amalgamations, but the time for floating such consolidations as those of 15 or 20 years ago is past. To say nothing of the difficulty of floating the great mass of securities required, public opinion on corporations has materially changed since 1900, and there would be strong and natural suspicion of an attempt to divide the steel trade between two great corporations.

It is quite possible that there may be some consolidations and combinations, but nothing on the scale of the Cleveland rumor is probable. Nor are all steelmen satisfied that the great combination is the wisest and most economical. Certainly it is not desirable from a technical point of view; a great corporation is not usually favorable to change or progress.

⁂

An interesting development in the mining industry that heretofore has escaped general attention is the fact that the Bawdwin mine of Burma is already producing. During the first six months of 1915 they are officially

reported as having produced 6500 long tons of lead, which is a very respectable output. An increase in the lead production of this great mine is to be expected later, when provision for the utilization of the zinc content and other values of its ore shall have been consummated.

BY THE WAY

When it comes to handling a "real-estate proposition" apply to the Department of the Interior. Ninety days ago the town of Anchorage, Alaska, was merely public land at the southwestern terminus of the new Government railroad. Now it has a population of over 2500, and nearly all branches of business are represented. On July 15 an auction sale of lots was held by the Alaskan Engineering Commission, and Chairman Edes telegraphed Secretary Lane the next day as follows: "Just returned from Anchorage. Sale in every way a success and everyone satisfied. About four hundred and fifty lots sold for one hundred thirty-three thousand dollars." Nearly $300 a lot was thus realized. Most of the lots were 60x140 ft., and streets, parkings and playgrounds were provided. Watch Alaska grow!

⁂

Never argue with an expert. It is useless. There is no way of making headway against him. Though you may know much more than he does, you can't possibly get him to admit it. His main defense lies in the possession of his own special vernacular. No expert, says *Life*, is complete without a vernacular. Many experts have nothing more. In arguing with an expert, he always begins by assuming: (1) that you don't know what you are talking about, and (2) that if you did know what you were talking about, you couldn't talk about it intelligently, because you lacked the specific vocabulary that the subject demands. As the argument proceeds he spends so much time asking: "Just what do you mean when you use the word —?" And you spend so much time explaining your terms that you totally forget what you are arguing about.

⁂

Two German ex-soldiers, Emil Propelle and August Tischer, brought into this country last year two packages of uncut diamonds from German Southwest Africa. They did not declare the stones when they landed here and were later arrested on a charge of smuggling. While doing military duty in Africa, they said they had grubstaked an old prospector who gave them the rough stones, now valued at $57,196, as their share. The ex-soldiers were tried and acquitted of the smuggling charge, but the German Government alleged that the diamonds were taken from the Colonial Mining Co.'s sorting department, and civil suits were brought. Since the war the German Government ceased its action, and yesterday Judge Hand ordered the litigation discontinued. Propelle and Tischer will now be allowed to keep the diamonds on paying $8000 customs duties.

⁂

The Similkameen Consolidated Copper Co., of Scranton, Penn., is circulating a prospectus about a group of copper mines at Voigt's Camp, near Princeton, B. C. In a quotation from a report on the property by J. C. Law it is said: "By process of computation, this area, reduced to square and cubic feet to the average depth of 500 ft. only, from which I deduct 10% as unmineralized (probably nearer 50%), resolves itself roughly into 815,000,000 tons of ore. Assuming that only 1½% of coarse copper is recoverable therefrom . . ." Continuation, in the familiar way. If the estimate of tonnage be anywhere near correct, Voigt's Camp has Chuquicamata "skinned to death" and Utah is merely an "also ran." But we're from Missouri.

⁂

Scientists have their troubles as well as ordinary people. Edward Hicks, a night geologist, according to the *Tribune*, was arrested on Long Island recently on a charge of chicken stealing. Hicks is a negro and found the night light most appropriate for his complexion and occupation. Here is the address to the court by which Hicks gained his release: "Jedge, youah honah, Ah wants to ask you, sah, did you evah heah of a night geologist? Dat's what Ah am, sah. And, jedge, youah honah, Ah wants to ask you, sah, did you evah heah of a scientific gem'man bein' 'cused of chicken stealin'? Jedge, youah honah, dey's not 'nuff words in all de langwidges to give expressin' to mah indignation, sah! Dis charge am mos' humilitin' to a membah of dat honorable prefession of night geologists of which, sah, Ah have de honah of bein' a humble and undistinguished membah." He showed his outfit, consisting of a lensless telescope barrel, being a "blind telescope" to locate rocks, a rock-tapping device and a textbook on rock composition. The court discharged him with the admonition hereafter to keep away from Plymouth Rocks in his geological researches.

⁂

The deepest gold mine in the world, the St. John del Rey in Brazil, is also one of the oldest. It has just paid a dividend of 1s. 3d. on its ordinary share capital, which makes a total of 10% for a year. The company earned more than 10%, but did not deem it desirable to pay a larger dividend at present. The reasons, explained Chairman Harris at the annual meeting of shareholders in London, were connected with the great object that they all had in view, namely, the prolongation of the life of the mine below Horizon 20, which meant that they would be working the mine at a depth greater than $1\frac{1}{10}$ miles under the surface. They were now working the lode at Horizon 18. Shaft G had been sunk to the level of Horizon 20, and crosscuts were being driven from the shaft to intercept the lode at Horizon 19 and Horizon 20. The time was therefore approaching when they would have to decide whether they should or should not take the necessary measures for working the lode below Horizon 20. Their decision would depend upon several factors, the most important of which were the size and value of the lode at Horizon 20. If the lode was as good as it was at the lowest horizon they were now working—Nos. 17 and 18—they would be encouraged to proceed. In regard to the ventilation of the mine, General Manager Chalmers had suggested that the air which was passed through the mine for the purpose of ventilation should first of all be cooled and dried, and then distributed through the workings. If the mine is to be extended below Horizon 20, considerable capital expenditure will be necessary.

PERSONALS

Howard W. DuBois, of Philadelphia, is in Alaska.

W. D. Pearce is in New York from Chihuahua, Mexico.

W. C. Weisbrod is expected in New York Aug. 10, on his return from Chile.

E. R. Eaton, of Greeneville, Tenn., is stopping at Crown Point, N. Y., for the present.

C. E. Drayer has been chosen secretary of the Cleveland Engineering Society, of Cleveland, Ohio.

C. A. Burdick has returned to New York from some professional work in the Province of Quebec.

Kirby Thomas has returned to New York from exploration work in the southwestern part of Virginia.

Dan C. Tobin, of Colorado, is in New York on business connected with the sale of the Midland mine.

E. O. Daue has severed his connection as manager of the Dolores Mines Co. at Madera, Chihuahua, Mex.

Clyde M. Pearce announces the opening of an office as mining engineer at Ironton, Minn., on the Cuyuna Range.

Prof. J. C. Gwillim, of Queen's University, Kingston, Ont., has been on a visit of inspection to the Porcupine camp.

John A. Rice, manager of the Curry mine, at South Lorrain, Ont., has gone to El Paso, Tex., on a short vacation.

A. R. Whitman, lately geologist of the McIntyre Co., has been engaged by the Peterson Lake Mining Co. to examine its property.

W. J. Dobbins, formerly superintendent of the Buffalo mill, Cobalt, Ont., who has been for some time in Florida, has returned to Ontario.

Dr. R. W. Brock, dean of the College of Applied Science, University of British Columbia, has returned to Vancouver from a trip to the East.

E. A. Ling, who has been for some time engaged on an asbestos property near Broughton, Quebec, has gone to South America for the National City Bank of New York.

George E. Farish is making a geological examination of the southern part of Rio Arriba County, New Mexico, for New York mining interests. He is assisted by H. Palsgrove.

Gerald Sherman, general superintendent of the mine department of the Copper Queen Consolidated, of Bisbee, Ariz., was a recent visitor at the Panama-Pacific International Exposition.

L. S. Blackman, who returned to the United States recently from Guanajuato, Mex., sailed on July 24 for Chile, having accepted an engagement with the Chile Exploration Co. at Chuquicamata.

E. Steidel, in charge of the Bureau of Mines mine exhibit and first-aid and rescue demonstrations at the Panama-Pacific International Exposition, has been advanced by the bureau from the position of junior to mining engineer.

M. F. Ortin, Minister of Commerce and Labor in Russia, recently visited the La Grange hydraulic mine in Trinity County, California, the largest hydraulic mine in the world. He was desirous of familiarizing himself with American hydraulic methods.

Dr. E. A. Schubert, of the commercial department of the Norfolk & Western R.R., has been investigating some iron deposits in Ashe County, N. C. The extension of the Virginia-Carolina R.R., now in progress, will furnish transportation for these deposits.

W. T. Partridge, who has had editorial charge of the iron and steel and metal market news of the "Journal of Commerce," New York, has resigned after a connection of a number of years, to devote himself to general writing in the lines in which he is well informed.

George W. Metcalfe, general manager of the Mammoth Copper Co., Kennett, Calif., has recently been a visitor to the Panama-Pacific Exposition, where he has installed a glass model of the Mammoth mine. This model is in the California exhibit in the Mines and Metallurgy Building, which was established by the State Mining Bureau.

M. S. Brandt has severed his connection with the Seneca Consolidated Gold Mines Co. and is returning to Boulder, Colo., where he will resume work for the White Eagle Mining & Smelting Co. He will also open an office for general mining work and will continue his operation of the Nil Desperandum mine on his own account.

Colonel Thomas Cantley, second vice-president and general manager of the Nova Scotia Steel & Coal Co., has been appointed president retaining the managership. The offices of first and second vice-presidents have been abolished. Governor J. D. McGregor, of Halifax, late first vice-president, and W. D. Ross, of Toronto, are made vice-presidents, Mr. Ross being constituted head of the financial department.

SOCIETIES

American Iron & Steel Institute—The fall meeting will be held at Cleveland, Ohio, Oct. 22 and 23, according to a decision of the directors at New York, June 25.

Arizona State Bureau of Mines—The formation of this body was authorized by the Legislature of the state at its last session and the appointment of the members has been announced by the Board of Regents of the University of Arizona. The director is Charles F. Willis, who has been for two years past director of the University Bureau of Mines, which has been merged with the new organization. The secretary of the Board is Miss A. M. Heckman, who was secretary of the University Bureau. The other members are E. K. Goettel late of the University of Illinois, V. A. Gleason, late of the University of Washington and J. D. Arozena, of the University of Arizona. Mr. Goettel will have special charge of the investigation of the rare metals; Mr. Gleason is a specialist in flotation and ore dressing and Mr. Arozena will have charge of assaying, mineralogical determinations and ore testing.

American Institute of Metals—Among the papers to be read at the annual meeting in September are the following: D. H. Newland, assistant state geologist, New York, "Albany Sand"; William W. Clark, Seymour Manufacturing Co., "Manufacture and Use of Alumino-Vanadium"; C. V. Powell, British Aluminum Co., Toronto, Ont., "Some Developments in Aluminum"; W. M. Corse, The Titanium Alloy Manufacturing Co., "Copper-Aluminum Alloys"; S. L. Hoyt, University of Minnesota, "Amorphous State of Metals"; S. W. Parr, University of Illinois (two papers), "Method of Analysis for Complex Alloys," "Development on Acid Resistance Alloys"; F. A. J. FitzGerald, FitzGerald Laboratories, "Electric Furnaces for Brass Melting"; H. T. Kalmus, Kalmus, Comstock & Westcott, Inc., "Cobalt in Non-Ferrous Metals"; Thomas F. Wettstein, United Lead Co., "The Effect of the Present European War on the Metal Industries"; Elwood Haynes, Haynes Stellite Works, "Stellite"; Prof. D. J. Demarest, Ohio State University, "Analysis of Babbitt Metals."

INDUSTRIAL NEWS

The Garfield Smelting Co., Garfield, Utah, is installing a 48-in. Symons disk crusher.

The Hardinge Conical Mill Co., announces that the Anaconda Copper Mining Co. is preparing to install 24 more of the 10-ft. diameter Hardinge mills. This makes a total of 44 out of a contract which they made early this year for 60 of these machines.

Morse Bros. Machinery & Supply Co., of Denver, Colo., has purchased the entire power plant recently erected near Wickenburg, Ariz. This plant was built to furnish power for the Octave Mining Co., 14 miles distant, the power being generated at the railroad and transmitted to the mine. The plant consisted of 200- and 550-kw. Westinghouse alternators driven by Corliss engines. The steam plant consists of B. & W. boilers, fired with oil. The transmission line was operated at 22,000 volts and is 14 miles long. All of this material will be dismantled and sold, or removed to Denver. The smaller unit was in use three weeks and the larger one was never used.

The present high price of zinc ore is having a stimulating effect in the Wisconsin zinc district. The Dings Electro-Magnetic Separator Co. of Milwaukee, Wis., has recently closed three contracts for magnetic separator equipment to be installed in that district. The Vinegar Hill Zinc Co., Platteville, Wis., continues to enlarge the National roaster at Cuba City and has just ordered another large battery of Dings magnetic separators. The Utt-Thorne Co., of Platteville, Wis., is overhauling the custom roaster at Benton, Wis., and has purchased considerable new machinery, including a battery of Dings magnetic separators. Kistler & Stevens, Platteville, Wis., is equipping a roaster plant and has ordered a Galena Iron Works roaster and Dings magnetic separators.

Editorial Correspondence

SAN FRANCISCO—July 21

The Bunker Hill Consolidated Mining Co. in the first half of 1915 mined and milled 42,087 tons of ore, producing a total value of $151,591, or approximate average of $3.60 per ton. The total value is divided as follows: bullion, $48,415; sulphurets, $100,608; rent of tailings, etc., $2568. Mill operated 175 days, 10 hours. The mining expense including payroll, supplies, power and water amounted to $85,113; milling expense including the same items, $8881; sulphurets expense, including assaying, freight and road repair, $5110; a total of $99,104. The general expense amounted to $9338, and a new drill sharpener, hoist control and office equipment added $1350 to the expenses. This makes an aggregate total expense of operation $109,792. In the period from January to June inclusive six monthly dividends were paid amounting to a total of $30,000. A significant fact is disclosed in the item of the net value of the bullion produced. The return of $48,415 from the crushing of 42,087 tons of ore shows a recovery value of $1.15 per ton. The return of $100,608 recovered from sulphurets shows the average value of the sulphurets to be $2.36 per ton. The tailing from the Bunker Hill mill is treated in a merry-go-round and cyanide tanks under a rental or leasing system. The exact value of the tailings is not stated in company reports but the value received from the rental, $2568, probably represents about one-half tbe total value. The Bunker Hill has paid dividends for several years under the mine superintendency of E. Hampton. Since the necessity arose for installation of a new steel hoist and development of new orebodies, the per share rate of the dividends has been reduced from 5c. to 2½c. The recent installation of Hardinge mills at the Original Amador mine, a neighbor of the Bunker Hill, is expected to prove decisively that regrinding and cyanidation may be as successfully applied to the characteristic Mother Lode ores in the Amador City district as in the Plymouth district, where the first Hardinge mills were installed.

Mine Rescue and First-Aid Training is being given mining men upon application to the United States Bureau of Mines at the Panama-Pacific International Exposition. The station is at the mine exhibit in the Mines and Metallurgy building, and is in charge of several competent men of the rescue force of the Bureau. The first-aid class has been in session from 9 to 11 a.m. daily excepting Sundays, each morning taking up a certain phase of the work so that an applicant would have to attend six classes to cover the entire course. Mine-rescue training is also given on request. This work is of such character that it cannot be done properly by special arrangement of courses, but every effort is made to suit the applicant. The demonstrator of rescue work will spend a good deal of his time in the field in August and part of September, so that the regular classes cannot be continued at all times during these months. Men desiring to take this course of training should make application about two weeks in advance so that they may be provided with competent instruction. A number of miners and mining engineers have taken these instructions and have greatly profited by them. The instruction has been extended to certain branches of the fire department in San Francisco. As a part of the exhibit of the Bureau of Mines, the various paraphernalia employed in rescue and first-aid work are on exhibition, competent men being engaged in giving information to all who ask it. The exhibitions including the mining and metallurgical divisions and the Mine, were awarded one grand prize, six gold medals of honor and two gold medals by the Superior Jury of the Exposition, and all the collaborators in these exhibits received silver medals.

Two Deputy Mine Inspectors, G. Chester Brown and J. W. Gebb have been appointed in the mine-safety department of the California Industrial Accident Commission. Mr. Brown is the senior member in point of time. Other deputies will be appointed from the available list of men who passed the civil-service examination, at such time as their services will be required. The organization of the mine-inspection department is not yet completed and will not be until the tentative mine-safety rules have been finally revised and put into operation. The progress of the inspection of mines under state and United States control has been as rapid as is consistent with the demand for thoroughness. The chief inspector, H. M. Wolfiin, continues to make visits into the mining districts pending the completion of the rules and this work will be augmented by the services of the two deputies. It is not unexpected that the rules may be in some respects materially revised, but as a basis for thorough organization and practical operation the tentative rules have served the purpose and with such revision as is deemed necessary will be put into operation under the provisions of the workmen's-compensation law.

BUTTE—July 22

The Passing of Amalgamated—The dissolution of the Amalgamated Copper Company, the last of this month, will mark the completion of an important and interesting chapter in the history of the copper and other industries. Under the fostering wings of this mighty corporation the Anaconda Copper Mining Co. grew to manhood, as it were, and to be old enough and big enough to take care of itself. The protector has outlived its usefulness and its protegee has grown so great that it is now about to absorb the holding company, awaiting merely the formal action of a board of directors to complete the consolidation. Although the early development of the Anaconda mines under the late Marcus Daly demonstrated the vast possibilities of this property, the launching of the Anaconda Copper Mining Co. in 1895 with a capitalization of $30,000,000 was received with amazement in Butte and Montana. Nothing like it had been experienced in the mining history of the state. Big as the Anaconda stock appeared to the people of Butte, it paled into insignificance four years later when the Amalgamated company was organized with a capital stock of $155,000,000 and with Mr. Daly as its first president. He was succeeded by H. H. Rogers who held the position until 1909 when John D. Ryan became the president. In 1910 Anaconda increased its stock to $150,000,000 and absorbed the properties of the Boston & Montana, the Butte & Boston, the Washoe, the Trenton and the Parrot and finally the Butte Coalition companies, the latter having acquired in 1906 the Butte properties of the late Augustus Heinze. This was followed by the purchase of the W. A. Clark properties, including the Original and West Stewart mines. Thus the Anaconda company grew by leaps and bounds into a concern as big and as influential as Amalgamated itself and in the 21st year of its existence it becomes its own guardian, a free agent, responsible to no other corporation. What this phenomenal growth of the Anaconda company means to Montana and to Butte in particular, is hardly appreciated to its full extent by those who live within its influence. At the present rate of production, Anaconda supplies the markets of the world with more than 300,000,000 lb. of copper per year. The company shares its prosperity with its employees, who receive the highest rate of wages paid to this class of labor anywhere in the world. The daily expenditures of the company for labor alone amount to $50,000. Its taxes reach the sum of $2000 a day. Thus the growing activity of the Anaconda Copper Mining company is a vital factor in the development and prosperity of Butte and the state as a whole, a prosperity that attracts attention throughout the country.

SEATTLE—July 11

A $100,000 Winter Dump was the result of the working last year on Ruby Creek, the largest cleanup ever made in the district. The cleanup, which was finished in June, more than filled a washtub with gold.

GALENA, KAN.—July 17

Promoter Mining Co. Under New Management—M. E. Kirsh has succeeded J. C. Welch as superintendent. The company is operating on a 40-acre lease which it has from the New Century, southwest of Galena. There are 10 shafts producing paying ore. This tract of land has only been opened up for about six months and is fast becoming a great producer. The company is preparing to build a new mill on the ground to enable it to handle the dirt that comes from the mines. Mr. Kirsh was formerly with the Cherokee County Supply Co., but resigned to take charge of the Promoter property. It is the intention of the company to push the development work as fast as possible in order to open up the land while ore prices are good.

Bailey Bros. & Co. on the Southside land is making about $10,000 a week from its mine. It has been in operation for about a year, but recently went to the 150-ft. level and encountered a rich run of ore. A year's cutting is already blocked out and the company is preparing to build a mill to handle the dirt, as the mine has become too large a producer to send the dirt to custom mills.

HOUGHTON—July 18

The Story that Henry Ford is putting considerable cash into several development properties in the vicinity of the White Pine, a subsidiary of the Calumet & Hecla, is vigorously denied by the officials of the companies so connected. There was one story to the effect that Ford had purchased heavily of Onondaga and another to the effect that he was interested in White Pine Extension. While it may be possible that Mr. Ford has bought stock in these companies the officers have no knowledge thereof.

SALT LAKE CITY—July 16

Mining Activity Is General throughout the state, and everybody is working. Attention is called by the National Copper Bank of Salt Lake City to the fact that it is more than five years since there has been anything like the lively interest in mining that prevails today. Many new prospects are being developed; new camps are being found; and old camps and mines are renewing their former activity. The change is not wholly due to the higher prices received for some of the metals, but in part to the restoration of confidence, which has been going on during the last year, and which would doubtless have caused money to be spent in mining development even without the stimulus of higher metal prices. Many lessees are working in Tintic, and Bingham and other camps and there is more activity in Big Cottonwood than ever before. In the south fork of the latter district 14 mines and prospects are working, and employing 130 to 140 men. These properties include the Cardiff, Maxfield, Kennebec, Day's Fork, Big Cottonwood Consolidated, Tar Baby, American Consolidated, Price, Carbonate, East Carbonate, Reed's Peak, Alta-Cottonwood, Baker Group, and Cardiff Extension.

Bingham & Garfield Railway has been assessed $24,000 per mile by the county assessor for Salt Lake County as compared to $13,000 last year. Efforts were made by the company to obtain a reduction before the county commissioners on July 9, when it was pointed out that the rate of assessment is much higher than that fixed by the state board of equalization on any other railroad in the county. At the hearing the commissioners declined to grant any abatement. The question of the rate of taxation of the railroad was made a political issue a year ago, and was one of the points raised at the fall elections.

DENVER—July 16

At Leadville, Pumping at the Penrose continues under the most favorable conditions. The cutting of the station has now been under way about a week, and it is thought that another equal period of time will see this part of the work completed. After that the station pumps will have to be installed, and it will probably be a couple of weeks before any effort will be made to lower the water past its present level. Some idea of the immense body of water that has to be drained may be derived from the task which the sinking pumps now have in keeping the water down below the station level. During part of one night last week one of the machines was shut down, and with the other working at full capacity it took the water only five hours to rise within a few feet of the station. With the two pumps running, however, it would be possible to drain the shaft still deeper with a lift of 470 ft. or more to throw the water. No trouble has been encountered in cutting the station. One side near the shaft was rather inclined to cave, but it proved more of a help than a hindrance to the work.

KNOXVILLE—July 12

The American Zinc Co. of Tennessee has begun work in the addition to its plant at Mascot. The company has within the last few months spent $75,000 to increase its concentrating mill so that increased output might be secured. The company recently purchased the Roseberry mill, and with a large force of hands is placing the old plant in condition to give an additional output of 400 tons daily. H. S. Kimball, president of the American Zinc Co.

FAIRBANKS—June 21

Tolvana Has 300 Prospectors Now. Owing to the lack of machinery and water the output for this season will probably not exceed $10,000. About $1000 has already reached Fairbanks. The gold from Livengood Creek assays from 905 to 920 fine and nets from $18 to $19 per oz. Olive Creek gold assays 903 and nets about $18 per oz. August Peterson has abandoned his lease on Olive Creek and will move his plant to McCord and McCarthy's ground on Livengood.

Tolovana Still Looks Good to the placer miners, although not enough has yet been found to prove that the camp will be more than a small one. Pay has been found at several points for more than a mile along Livengood Creek and on several adjacent creeks, of which the most important seems to be Olive. Among the more recent discoveries may be mentioned that of Sullivan & Johnson, who have found pay at a depth of 118 ft. on the fourth-tier bench claim, right limit of Livengood. This pay is 500 ft. toward the hill from that lined up by Cascaden, Wagner and others, and is held to indicate a very wide paystreak. Dollar ground has been found on Gertrude Creek, a small "pup" entering Livengood at 5 Above Discovery. This paystreak is said to be about 12 ft. wide. Teddy Hudson has bonded No. 5 Above to Tom Knowles for $12,000.

TORONTO—July 24

The Government of Ontario on July 20 announced the appointment of a commission to enquire into the feasibility of refining nickel ore entirely within the province. The committee consists of George J. Holloway, London, England, chairman; Dr. Willet G. Miller, provincial geologist, Toronto; James McGregor Young, K. C., Toronto; and Thomas W. Gibson, Deputy Minister of Mines, Toronto, Secretary. The appointment of Mr. Holloway, as chairman, was made as the result of a consultation with the British Government, which desired that a competent metallurgist should occupy the position. In taking steps to secure an entirely suitable man, the British Institute of Metals was approached and Mr. Holloway was recommended as in every respect qualified for the post. He is an associate of the Royal College of Science, London, examiner in metallurgy in the Institute of Chemistry and University of Birmingham, and vice-president of the Institute of Mining & Metallurgy, London, in addition to holding other responsible positions. James McGregor Young is professor of constitutional and international law at Toronto University. No time will be lost in beginning the investigation. The Commission or some of its members will probably go to Norway to investigate the refining process employed in that country, and it is expected that at least one of the commissioners will visit New Caledonia to examine the methods in use there.

GUANAJUATO—July 15

Difficulty of Getting Supplies of any kind into the mines, or of shipping bullion from them, has necessitated a considerable curtailment of operations. It was intended to discontinue operations entirely on July 1, but it is not certain whether or not this has been done. Supplies of cyanide and other essentials to operation have been divided among the mills in order to postpone cessation as long as possible. If operations could be continued, that is, if supplies could be obtained, the operating companies would earn more money than in normal times, since they are purchasing ore on extremely favorably terms, and holding bullion until the proper opportunity appears to ship it out of the country and obtain payment in gold, or credit on that basis. About 100 Americans are still in the camp, but most of those having families have left or sent their families away. One recent arrival reports that it took him about 12 days to make the trip from Guanajuato to Vera Cruz, a journey which ordinarily can be made in 24 hours.

Pinguico Mine and Mill of the Guanajuato Development Co. has been abandoned some time ago due to the working out of the orebody. This property had a meteoric existence, having been discovered only since the operation of foreign companies on a large scale in Guanajuato. The Development company took over the mine, opened it up and milled ore averaging more than one kilo in silver for some years. The mill was a modern sand and slime installation of 200 tons daily capacity, but since the exhaustion of the mine, has been dismantled and used in other places. The San Matias mill and the Peregrima mill of the Development company have been worked as long as supplies could be obtained.

Guanajuato Reduction & Mines Co. has been operating the mill as long as supplies lasted, extracting some ore from the mines and filling up the remainder with purchased ore. Guanajuato has been annoyed by descent of large bands of the armed followers of one or another of the forces now combatting for power but has not been subjected to systematic looting as has been the case at Leon, the largest city in the state of Guanajuato. General Obregon, upon his entry into Leon, granted his soldiers a 3-hr. privilege of looting indiscriminately. At the end of that time little of value remained in Leon.

The Mining News

ALASKA

BONANZA COPPER MINING CO. (Valdez)—Ore on this property is now running about 70% copper and shipments so far average about $1,500,000 per month.

AMERICAN SMELTING & REFINING CO. (Tacoma, Wash.)—Copper refinery here, following a conference of this company and the Tacoma Smelting & Refining Co., will be doubled in capacity this summer.

NEW PLACER STRIKE has been made on Hadxana River opposite mouth of Birch. Find made on Trout Creek, but ground has not been sufficiently prospected to demonstrate extent of pay. Discoverers found 3 oz. of gold in the bottom of their first hole.

McWHORTER and ARTHUR (Stewart River)—New and permanent quartz camp has been established on Stewart River by development of this mine on Galena Creek in Mayo district. Shipment of 1500 tons silver ore recently made from mine to Tacoma smeltery and is expected to return $300 per ton.

THREE-MAN MINING CO. (Valdez)—Shipments of 800 tons made from this property on Landlock bay so far this year, and from 200 to 400 tons of picked ore will be shipped to smelter each month during balance of year, with larger shipments as facilities for handling are bettered. The present high price of copper is making the ore particularly valuable.

GRAFTER MINE (Whitehorse)—Closed down several years ago, is to be reopened and shaft, partly filled with water, now being pumped dry. Approximately 200 tons high-grade copper ore on dump now from old workings. With high price of copper many of the other copper properties of this district will start operations. J. P. Whitney, E. A. Dixon and George Armstrong are the owners of the Grafter.

THE MOST VALUABLE CARGO LEAVING ALASKA in the history of territory has recently cleared from Cordova on Steamer Mariposa of Alaska Steamship Co. carrying a cargo valued at $1,600,000, which consisted of 1200 tons of copper ore, $840,000; gold dust and bullion, $700,000; and raw furs from interior, $60,000.

ALASKA TREADWELL MINING CO. (Juneau) — Power plant for the Alaska Mexican claim of this company has been completed and is now in operation. Consists of one 750-kw. turbine and one 2000-kw. turbine, which are in addition to the former two units of 1000 each. A small log-crib dam was constructed during the winter at one of the power plants in order to increase the head with a corresponding increase in power. Lower part of mine is now being opened up by levels driven into it from 700-ft. level of Alaska United Co.

READY BULLION (Juneau)—Work started on a new incline shaft equipped with electric man- and ore-hoists, with steel headframe which will open up mine at a depth of 200 ft. below present level (2200 ft.). Old incline shaft started in footwall, but owing to unexpected straightening up of vein, is now well in the hard, greenstone hanging wall. The new shaft will keep entirely in the footwall slate, and will release large bodies of ore now remaining in the mine to support the old incline shaft where it crosses from the foot to the hanging wall.

NO. 13 ABOVE, FAIRBANKS CREEK (Fairbanks)—Allis-Chalmers 5-stamp mill shipped into Fairbanks district by Edward McConnell several years ago has been bought by Thomas Gilmore, who plans to erect it on No. 13 Above Discovery, Fairbanks Creek, adjoining Steilig custom mill.

RHOADS-HALL (Fairbanks)—J. H. Patterson plans to recrush accumulated tailing from Rhoads-Hall mine in tube mill that he is building in Fairbanks at shops of Samson Hardware Co. Mill is an experiment but Patterson hopes to recover several dollars a ton from tailings, and prove feasibility of undertaking.

GREAT INTEREST IN STIBNITE is being shown by Fairbanks quartz miners since Silas Scrafford shipped 120 tons of hand-picked antimony ore from the property of the Chatham Mining Co. Many gold-quartz veins carry stibnite, chiefly as isolated bunches comparatively free of quartz and barren of gold. Smith & McGlone plan to make test shipments from head of St. Patrick's Creek and Thomas Lloyd plans to send a small lot from Kantishna. Transportation companies have reduced rates to encourage industry.

ARIZONA

Maricopa County

BUFFALO-ARIZONA (Hot Springs)—Harry J. Bennett, of Phœnix, and associates have begun shipping copper ore to smelter at Humboldt. Considerable 15% ore on the dump.

Mohave County

CHARCOAL CAÑON (Kingman)—A. W. Clapp carrying on development work. Good orebody uncovered. Ore is lead carbonate mostly, but in shallow shaft a fine body of galena has been struck.

Cochise County

NEW CORNELIA (Ajo)—It is estimated by President Charles Briggs of the New Cornelia Copper Co., which is a subsidiary of the Calumet & Arizona company, that the pit equipment, power houses and other necessary works for the proposed 4000-ton leaching plant will cost over $3,000,000.

Yavapai County

ANTELOPE PARK (Rich Hill) — Dan B. Genung purchased mineral holdings of Harrison Yarnell. Preparing to develop the property on a large scale.

CALIFORNIA

Sierra County

MONARCH and CLEVELAND (Sierra County) — Quartz mines, being developed by R. G. Gillespie, of Pittsburgh, Penn. Mill running steadily on good ore.

PLUMBAGO (Alleghany)—Fifteen-stamp mill to replace plant destroyed by fire was built in less than one month and is running on rich ore, many hundred tons of which are blocked out and in sight. Owned and operated by Croesus Mining Co., of New York. W. B. Pearson in charge.

SACRED MOUNT (Sierra City)—Cyanide plant completed and in operation on tailings which assay over $9 per ton. Jay C. Folsom in charge.

SOUTH FORK (Forest)—Gravel and quartz. Vein has been encountered which is believed to be same as that in famous Tightner mine at Alleghany. Splendid returns being received. C. Weeks, of Los Angeles in charge.

SIERRA BUTTES (Sierra City)—Oldest quartz mine in Sierra County, and second oldest in California, operated continuously since 1851, has developed a new ledge 6 ft. wide, with 1100 ft. of backs, containing a payshoot that will practically make a new mine of the property. Hayes Brothers, of San Jose, owners. J. E. Westall in charge.

Shasta County

SALE OF ASBESTOS CLAIMS, 44 in number, and located on Mears Creek west of Sims, made recently to San Francisco men.

DREDGE INSTALLATION ON COTTONWOOD CREEK, near Gas Point, being made. Dredge of large capacity. Quarters for employees also being built.

NOBLE ELECTRIC STEEL CO. (Heroult)—Daily production 10 tons ferromanganese being made with one furnace. Second furnace to be started within few days. Ore is supplied by mines in Modoc county. Force of 80 men employed at plant.

MAMMOTH COPPER MINING CO. (Kennett)—Mine and smelting plant operating steadily. In addition to copper ore smelted, large tonnage 40% zinc ore being shipped to Oklahoma smelting plants.

MOUNTAIN COPPER CO. (Keswick)—New 250-ton concentrating plant put into operation recently. Only low-grade ore of mine concentrated; this is pyrite and chalcopyrite in silicified ground mass. Jig concentration used. On July 10, Shay locomotive of down-coming company ore train jumped track at trestle. Engineer and fireman killed.

BALAKLALA (Coram)—Prominent metallurgical men visited smelting plant recently. Statement given out by Mr. Newhouse indicates plans being made for resumption of operations at Balaklala smelting plant, Coram, after installation of some fume-precipitation process, probably latest Cottrell improvements. Smelting plant was closed July 1911 by "smoke suit" brought by farmers of valley.

Amador County

SOUTH EUREKA (Sutter Creek)—June dividend was paid July 15. Eighty-stamp mill in regular operation and 250 men employed. William H. Schmal is superintendent.

Butte County

EUREKA (Magalia)—This mine, on Little Butte Creek, has been purchased by Frank E. Whitlock and associates. Property was a good producer in early days.

SUCCESS & RUSSELL (Oroville)—G. W. Rumble, of Berkeley, made defendant in damage suit for $25,000, brought in Superior Court in Oakland by Barton Pitts, of Oroville. Pitts charges he was falsely accused by Rumble and arrested on a charge of stealing ore. Rumble was later arrested on a charge of perjury in connection with suit brought by B. J. Coglan to collect $5000 commission. Rumble has been in similar troubles connected with mining operations.

STEIFER MINING CO. (Chico)—Stockholders filed amended complaint in Superior Court asking that $51,000 assessment, recently levied by the directors, be declared invalid and directors restrained from selling stock for nonpayment of assessment. There are 530,000 shares, of which Steifers owns 209,064. Amended complaint alleges these shares were given Steifer by directors and that P. B., H. M., M. V., and Mary Steifer form majority of the directorate. The other members are J. M. Cline and Erasmus Wilson. It is also recited that two mortgages totaling $89,000, held by Mary Steifer against company are fictitious and that thousands of dollars expended in construction was done merely to make a showing and not for benefit of mine.

Eldorado County

RYAN (Shingle Springs)—Machinery being assembled for installation at this mine at Frenchtown, recently purchased by N. B. Ryan, of Manhattan, Nev. A 100-ton crusher will be installed.

COFFIN & REED (Placerville)—San Francisco men are negotiating for purchase of property and also Linden mine, owned by Stricker Co. Linden has been a producer. A 1400-ft. tunnel has been driven to work both mines, from which upraises will be run.

Kern County

WERINGER (Woody)—High-grade copper ore reported in addition to large body of medium-grade ore. This encourages contemplated installation of a 200-ton John D. Fields leaching plant. Plant will be electrically operated and will cost $35,000.

COLORADO

Boulder County

HERALD (Boulder)—R. M. Davis received settlement for lot weighing 8 tons. Net returns, $1287.50 assay showing 9.73 oz. gold and 5.50 oz. silver. Has wide vein from which he will be able to make similar shipments while reserving ore suitable for milling later.

FOREST HOME (Nederland)—While sinking shaft in this property of Boulder Tungsten Production Co., miners broke into flooded workings of Cold Springs No. 2 mine of Wolf Tongue Co. Nobody injured, but incident has aroused a question as to apex rights that may result in litigation. Cold Spring vein being one of best producers of Wolf Tongue Co. During past two years, leasers Munson and McKensie have shipped good tungsten ore from this vein. William Barnett, 82, while trench-mining, was killed by cave-in, on July 12.

San Miguel County

TOMBOY (Telluride)—New electric hoist installed at the Cincinnati shaft, to raise ore from Montana property to mill level. During June 100 cars of ore and concentrates were shipped from Telluride to the smelters. Shipments include 24 cars from Smuggler-Union, 12 cars from Liberty Bell, and 55 cars from Tomboy to the Durango smelter; and 8 cars of zinc concentrates from Colorado-Superior Mining Co. to Blende.

Teller County

LAST DOLLAR (Altman)—Contract has been awarded to sink the shaft 100 ft. to total of 1480 ft. Probable that sinking will be continued after completion of contract. Development operations in progress on 900-ft. level on company account, and four sets of lessees carrying on exploratory work in other parts of property. Much payable ore opened. M. B. Rapp, manager.

JERRY JOHNSON (Cripple Creek)—Cripple Creek Deep Leasing Co. has outlined plans for extensive campaign of development in this Ironclad Hill property. Lease has been secured on all ground below 650-ft. level and sinking will begin within a few weeks. The company proposes to sink shaft another 500 ft. Working fund of $25,000 has been provided to carry on work. New 100-ton cyanide mill nearing completion and will probably be ready for operation within next 30 days.

San Juan County

EMMA (Silverton)—J. A. McCrimmon is having a carload of heavy lead ore packed on burros from this mine in Ice Lake basin.

BIG GIANT (Silverton)—Peter Orella has developed a large shoot of milling ore and is shipping stuff from the high-grade streaks.

SILVER LEDGE (Silverton)—Louis Bonavidi, operating the mill under lease, is running steadily and making lead concentrate and zinc concentrate.

PRIDE OF THE WEST (Silverton)—John B. Giono is shipping small tonnage of high-grade while developing large body of low-grade milling ore.

MICHIGAN

Iron

WHITE PINE (White Pine)—Question of railway connections seems unsettled at present time.

PEWABIC (Iron Mountain)—Management has given orders to work on full time. Men have been working four days per week for a number of months. The mine will soon be exhausted of merchantable ore. Fifty miners have been added.

NORTH LAKE (Houghton)—Is sinking at the rate of 50 ft. a month on the way from the 340-ft. level to 800-ft. depth. Osceola lode at any time now.

NEWPORT (Ironwood)—New record for loading iron ore on Gogebic range made few days ago at Newport. In 10 hr. one shovel loaded 162 cars from stockpile. Nearly 8000 tons handled by one shovel. The best previous record held by Colby at Bessemer. That mine loaded 150 cars in same time.

SOUTH LAKE (Houghton)—New compressor is in operation and four more drills will start at work Tuesday, making 12 machines in all at work in this mine. They are increasing the stock pile to good size and shipments of rock will start very soon.

NEW ARCADIAN (Houghton)—Will probably make another shipment of rock before the end of this month. This rock will come from the south drifts and will be sent to the mill and smelter for the purpose of getting a good line on results that can be expected from southern openings. At the present all energies underground are directed to the development of the amygdaloids. No drilling is being done at present on the conglomerate recently opened.

FRANKLIN (Houghton)—Crosscut expects to hit the orebody and plans for further development depend on its character where cut. In the meantime the showing in the Allouez conglomerate continues rich. Eighteen machines are in operation and most openings are in better character rock than expected. Electric haulage will be installed immediately, meaning a saving in rock handling underground and an increase in rock shipments to 1200 tons per day.

HANCOCK (Hancock)—Is shipping 400 tons per day, average, but working 30 machines. Four of the Pewabic series are being opened, Nos. 3, 4, 8 and 9. This latter is the richest of the series and No. 4 is next in copper content. Good-grade rock is coming out and increase in shipments can be figured shortly. To date there are no smelter returns on the limited shipments already made. Work through the Quincy shaft likely to commence soon.

COPPER RANGE CONS. (Painsdale)—In addition to fact that both Baltic and Champion mines today are turning out richest continuous production of high-grade copper in their history fact also is generally known that all of development work underground is showing better-grade of rock than average in lives of these two mines. Trimountain continues to improve materially. From 20 to 27 levels of No. 2 good ground is developing. In Baltic, shoot from 28 to 29 levels in No. 3 is showing good ground.

MONTANA

Granite County

BOULDER MINING DISTRICT—Bond and lease has been taken by Butte parties on Bluebird group of mines, six miles above Princeton. Group consists of eight claims on which about 2200 ft. of tunneling has been done. Ore on different claims runs on an average of $67 a ton in gold and silver, copper and lead. The Butte men will start development work within a few days.

Mineral County

IRON MOUNTAIN MINE (Missoula)—Federal Mining & Smelting Co. bought this mine at a sheriff's sale, with mill and equipment for $111,000; 10% down, balance on delivery of deeds and possession. Company also owns power line, 11 miles long to Paradise, fully equipped power plant and substantial buildings. Mine located about three miles from Superior, the county seat. It is a silver-lead producer and hundreds of thousands of dollars were taken from it in the early days. Production began 14 years ago and lasted for 8 years, during which company paid more than $500,000 in dividends besides building a 250-ton mill and 15 miles of mountain road.

BUTTE & SUPERIOR MINING CO. (Butte)—Concentrates valued at $118,787 per ton recovered by oil-flotation process in company's mill during June, according to monthly statement filed in Federal court in compliance with order of court made in suit brought by Minerals Separation Co. Assays are highest recorded in mill in months, 36,206 tons of ore were treated in June and 8397 tons of concentrates were recovered at a cost of $4.08 per ton.

BULLWHACKER COPPER CO. (Butte)—Company is taking out ore at present from its property at rate that warrants fair profits from now on. During June, 37 cars of ore were shipped, for which a total of $3651 was received. June pay roll was $2748; net profits after paying all expenses were over $500. During July tonnage is being increased gradually and it is probable that there will be a profit of from $2500 to $3000 or close to $100 per day.

RAVEN COPPER CO. (Butte)—Notices have appeared in the daily papers that on Aug. 4, 1915, this company will sell at public auction to highest bidder, at Centerville, near Butte, all of its property in Silver Bow County, consisting of Raven lode-mining claim and interests in other smaller ones. Also town lots, mining and surface rights together with all buildings and improvements, all machinery and equipment. Sale to be held at shafthouse on Raven claim. Deposit of cash to the amount of $25,000 or a certified check for that amount, will be required before a bid will be accepted. J. A. Poore, Butte, is authorized to give further particulars. Raven is one of the older properties on the Anaconda hill and has been a large producer in days gone by. It has been idle for several years.

Beaverhead County

BOSTON & MONTANA DEVELOPMENT (Elkhorn)—Crosscutting to central veins has been started from 2000-ft. point of the big main tunnel, and it is expected that one of them will be reached within a distance of 300 ft. depending on dip of veins. Good reports of developments and mineralization are being made to Butte office by Superintendent Hopkins.

ARGENTA MINING DISTRICT—A deal has been closed involving Lewis Phillips and Rittenhouse claims, and Rittenhouse millsite in this district. Property turned over to Alexander Walker of the National Oil Co., who represents outside interests who contemplate the development of large orebodies exposed in present workings and on surface. Ore exposed in said workings as high as 60% lead, 50 oz. silver and $7 in gold. On south end of property opencut work has shown good values in copper, gold and silver.

Silver Bow County

BUTTE DULUTH (Butte)—Captain Wolvin has been in New York for several months trying to raise funds to relieve financial situation. Now stated that he has been partially successful and will soon be back in Butte.

DAVIS-DALY (Butte)—Stoping begun on new orebody on the 2500-ft. level of Colorado mine. Orebody opened for 150 ft. and is reported to have average width of about 5 ft. and carry 4% copper.

ALICE MINE ORDERED SOLD BY COURT—Judge Bourquin in United States Court at Helena signed interlocutory decree July 3, under which property of Alice Gold & Silver Mining Co. will be offered for sale. Order made in action brought by Peter Geddes and other minority stockholders in Alice, who wanted sale to Anaconda company set aside. John Lindsay of Butte named as special master for purpose of carrying out decree. No bid for property below valuation at which property was taken over by Anaconda company will be considered. If no sale is made, then previous sale to Anaconda company will stand. Fifteen hundred dollars for 45 tons of ore taken from lease in Alice mine is the amount paid recently to mining man of Walkerville. Price averages $33.33 a ton and is for silver ore. There are number of leasers on Alice, as well as in other properties in Walkerville district. Unpatented claims to north of Walkerville for distance of two miles present busy outlook. More assessment work being done this month on over hundred claims. Tom Weber, one of leasers on West Salvador, has struck 6-in. silver vein at depth of 75 ft. Dave Davis has lease on same claim; is sinking 90-ft. shaft.

BUTTE-BALLAKLAVA (Butte)—Anton Donati and others have started suit against company to recover profits on lease of portion of company's mine. It is claimed plaintiffs and company entered into an agreement Feb. 1 last, in which former were to mine on 1600 level of property; that work was started on Mar. 17 and continued until Apr. 5, when plaintiffs were ordered to quit and surrender possession of place. It is alleged that company shipped ore from portions of which plaintiffs should have received $575.84. It is also claimed that 50 cars of ore were left in place from which they should receive as their share $5500. They say contract called for 30 days' notice before it could be terminated.

ACTIVITIES IN DISTRICTS TRIBUTARY TO HELENA—About 50 tons of ore are being treated daily and force of 25 men is employed in mine and mill of York Mining Co. whose property is located across Missouri River near Helena. L. D. Armstrong who is working two claims in Minnehaha gulch two miles above Rimini, started tunnel, last 60 ft. of which has been in ore running from $30 to $40 in gold and silver. Frank Jama, who is working prospect at head of Lump Gulch, struck vein of galena and lead-silver ore running $80 per ton. Ed. Hersky and associates of Helena have promising property in Centralia group, two miles south of Blossburg whence they are shipping ore every month that averages from $700 to $800 per car.

BUTTE-ALEX SCOTT (Butte)—Has declared dividend of 15c. per share. Local shareholders had expected 50c. New hoisting engine has been ordered and will be installed by Sept. 1. New headframe will also be built during August. Shaft will soon reach the 2200-ft. point and a new level will be opened. New cages and 3-ton skips also to be installed, all proposed improvements to cost about $25,000. About 200 tons ore per day hoisted. Will be increased to 300 and 350 tons. June production about 500,000 lb. copper.

TUOLUMNE (Butte)—Officers of company are still urging shareholders to "come through" with loans with which to provided a fund for resumption of operations, but responses are not very general. About $20,000 pledged and about $15,000 more is wanted to pay running expenses for a month or two until returns from ore shipments come in. There is a large quantity of ore in the upper levels of the Tuolumne that can now be mined at a profit. Years ago, when present management worked mine to make a showing, when insiders waived dividends and public was paid from the profits of high-grade ore that was mined, this low-grade was left undisturbed. In those days stock, on the company's fine showing and dividends, went to $5 per share, and when some facts became public it dropped to about 25c. per share. Now around 45 cents.

NEVADA

Esmeralda County

TONOPAH BELMONT (Tonopah) has cut 6 ft. of rich ore in raise above 1100-ft. level.

RESCUE-EULA (Tonopah) has broken through wall of main ledge on 900-ft. level.

MONARCH-PITTSBURG (Tonopah)—Northeast crosscut on eighth level has broken into commercial ore. Ledge cut is farthest west in district.

WEST END (Tonopah)—Is installing electric hoist below 600-ft. level in Butler ground, and will immediately begin extraction of ore under stipulations entered into recently.

Storey County

UNION CONSOLIDATED (Virginia City)—West crosscut on 2650 level extended to 710-ft. point, the face being porphyry and quartz.

OPHIR (Virginia City)—Saved 280 cars of mill ore from Central tunnel and milled 270 tons. Favorable indications throughout tunnel level in development work.

MEXICAN (Virginia City)—From 2300 level delivered to the mill bins 390 tons of ore, average assay value $8 per ton. Reopened main Comstock lateral drift on 2500 level. Crushed 135 tons of ore, averaging $8.26 per ton.

JACKET-CROWN POINT-BELCHER (Gold Hill)—Received at mill 668 tons of dump rock and 199 tons of mine rock; shipped bullion to smeltery. New stope being opened in Belcher 1200 level, and 67 cars of mill ore saved.

UTAH

Summit County

PARK CITY SHIPMENTS for week ended July 9 amounted to 3,276,197 lb., by five shippers, the output being lessened somewhat by Fourth of July holiday.

MINES OPERATING (Park City)—Machinery from company's property being shipped to Tintic to be used at new plant to be constructed by Tintic Milling Co. Contract for excavation and building will be hurried so as to have plant in operation by Jan. 1, if possible. Geo. H. Dern is general manager.

Salt Lake County

SELLS (Alta)—Eight or 10 in. of sulphides carrying lead and silver being followed in south drift. Mineral-bearing ground opened for 150 ft. Two shifts being worked.

BINGHAM-NEW HAVEN (Bingham)—Parr lease at this property reported to be making money.

SOUTH HECLA (Alta)—Wedge orebody being prospected for on the 500 level, and 200 ft. additional work will be necessary to reach it.

CARDIFF (Salt Lake)—New equipment, including electrically-driven compressor, being installed. Surface improvements also are being made. Fifty-five teams hauling ore.

WASATCH MINES (Alta)—Zinc ore being shipped from the deposit on the hill, and lead-silver-copper ore from No. 5 stope of main workings. Indebtedness has been reduced to about $5000.

UTAH COPPER (Bingham)—Now operating at 100% capacity for first time in its history. Stripping is now so far advanced that mine can produce tonnage as rapidly as any increase in milling capacity can be constructed. One day, recently, 28,000 tons of ore were treated in mills whose original capacity was figured at 21,000 tons. It is believed that this can be increased to 30,000 tons per day without further construction cost.

UTAH-APEX (Bingham)—Some changes being made at the mill. Settling cones being taken out, and large shallow tanks installed, possibly also flotation machinery. Electromagnetic process may be employed later to separate lead and zinc. Daily shipments of 125 tons of lead ore and 100 tons of concentrates being made. Two miners caught in between Minnie and Andy tunnel levels were rescued after 20 hr. of imprisonment.

Iron County

SILVER PEAK (Lund)—Articles of incorporation have been filed by this company owning six claims in Blair district, 25 miles south of Lund. Capitalization is $10,000. R. B. Shepherd is president. Development consists of several shafts, and property has been opened to depth of 175 ft. There are about 60 tons of silver-copper-gold ore on dump.

COPPER ZONE (Lund)—This company, recently organized, will work claims in south Bullion Cañon, about four miles from Silver Peak. Capitalization is $10,000. There are two shafts, one 100 ft. deep, and one 200 ft. W. W. Wiscome is president.

Box Elder County

GRAND VIEW MINING (Ogden)—This company has been incorporated to develop zinc ore in neighborhood of the recent strike on Promontory Point. Capitalization $500,000. Incorporators are Chas. H. Smith president; O. H. Mohlman; G. Vaughn; W. P. Watson; G. Manning. Zinc ore of good grade opened recently on Promontory point, and is being shipped at a profit.

Juab County

GODIVA (Eureka)—Lead-silver ore with some gold being mined by lessees, from four blocks of ground.

RIDGE & VALLEY (Eureka)—Lessees mining lead-silver ore from 900 and 1100 levels. Work being done through the Gemini.

TINTIC SHIPMENTS FOR WEEK ended July 9 amounted to 131 cars by 21 shippers, as compared to 169 cars the week preceding. Lessened output being due to closing down of most of the mines over the Fourth.

LOWER MAMMOTH (Mammoth)—Ten blocks of ground are being worked under lease, from one of which—on 1500 level—car of 40% zinc ore was shipped week ended July 2. Company is producing silver-copper ore from 1000 level.

IRON BLOSSOM (Silver City)—Quarterly dividend of 5c. per share, or $50,000, declared, payable July 26. Heretofore regular rate has been 10c. per share, and thus far in 1915 $200,000 has been paid. Total to date amounts to $2,420,000. June shipments were 86 cars.

McINTYRE MILL (Silver City)—Several thousand tons of tailings from one of early mills on McIntyre ranch are to be marketed. These will be loaded on cars of S. P., L. A. & S. L. railroad near ranch, and shipped to Garfield. Value is principally copper, with some silver and gold.

GOLD CHAIN (Mammoth)—Ore carrying lead, silver and gold has been opened from 1500 level of Lower Mammoth, and shipment has already been made from this strike, considered one of most important in over a year. When orebody has been further developed connections will be made with main Gold Chain workings. Ore is being mined on 300-, 400-, 500- and 700-ft. levels. Eight cars were shipped in June.

CHIEF CONSOLIDATED (Eureka)—Dividend of 5c. per share been declared, payable Aug. 2 Rise in the price of lead added materially to earnings. Property is one of heaviest shippers in Tintic. Extensive leasing operations recently been inaugurated. Several additional mining claims in North Tintic lately acquired. Water secured for Scotia mine in West Tintic under lease to Chief, and pipe-line about a mile in length being laid so that this can be pumped over to mine and do away with hauling water from Cherry creek.

CANADA

Ontario

SCHUMACHER (Timmins)—Shaft down 440 ft. and being put down to 600-ft. level. Wide quartz vein has been cut at 300-ft. level.

TRETHEWEY (Cobalt)—Directors have been authorized by shareholders to purchase a controlling interest in the Rochester mine, on which work has been suspended for some years.

DOME LAKE (Porcupine)—Weekly cleanup July 15 realized over $5000. Vein on 400-ft. level 18-in. wide, said to run $20 per ton. Good ore also encountered in winze being put down from 180-ft. level.

VIPOND (Porcupine)—Strike recently made on 400-ft. level shows rich ore. Another find made on 200-ft. level. Management decided to issue a regular monthly statement.

HAYDEN (Timmins)—Camps for accommodation of 80 men have been erected. Plant comprising a compressor and hoisting outfit will be put in. Shaft down 100 ft. and two orebodies have been encountered. Ore growing richer with depth.

McINTYRE (Porcupine)—Has purchased controlling interest in Pearl Lake and new company will be formed to operate it, to be known as McIntyre Extension. Deal gives McIntyre use of the Pearl Lake shaft, 600 ft. deep, close to their boundary, and economies can be effected by joint operation.

PORCUPINE-CROWN—Between 50 and 60 tons of tailings already treated by amalgamation is being put through cyanide plant daily to extract residue of gold. Tailings have average gold value of $3.15 per ton and company has 15,000 tons on hand.

TEMISKAMING (Cobalt)—Statement for June shows bullion in storage and bagged ore amounting to 730,270 oz., valued at $350,000. In new vein system opened up on 400-ft. level there is vein 5 in. wide of 3500-oz. ore, which has been drifted on 135 ft. and is now within 20 ft. of Beaver line. New hoist being installed to reach lower contact between diabase and Kewatin at depth of about 1600 ft.

SOUTH AMERICA

Colombia

NECHI MINES (COLOMBIA), LTD. (Zaragoza)—Oroville Dredging Co., Ltd., parent company, reports that Nechi dredge is expected to be ready by the end of August to start work on San Francisco property, opposite the Pato.

The Market Report

Metal Markets

Again all of the principal metals were weak and reactionary, the declines in copper and spelter being considerable, while those in tin and lead were relatively slight.

Copper, Tin, Lead and Zinc

Copper—The market was dull and quotations throughout the week are essentially nominal, the producers transacting scarcely any business. Many of them were, however, trying to find a level upon which copper would move, and in their efforts they were more active than in the previous week. The transactions reported among dealers were devoid of significance, for the producers would not show their hands on relatively trifling business. All through the week copper was obtainable in round lots at sharp concessions, and during the latter part was to be had at 18@18¼c., regular terms, equivalent to about 17.80@18c., cash, New York. At the close of our week of record there were indications that domestic consumers would become interested at the existing level, or a shade lower.

The British Government decided to release raw copper for export with certain stipulations and guarantees, as we indicated last week. Some of such copper is now on the way to American refiners.

Copper Sheets have brought 25@26c. per lb. The principal manufacturer makes no base quotations. Wire is quoted at 21@21½c. per lb. at mill.

Copper Exports for the week ending July 10 are reported by the Department of Commerce at 5,934,615 lb., the larger items being 2,240,939 lb. to Russia, 1,612,389 lb. to France, 976,576 lb. to Italy and 922,763 lb. to England. Imports for the week were 6,742,089 lb. metal and 3,232,545 lb. in ore and matte; 9,974,634 lb. in all, from Japan, Canada, Chile and Cuba.

For the week ended July 17 the total exports were 6,361,262 lb. Imports were 6,021,033 lb. metal and 2,065,286 lb. in ore and matte; 8,086,319 lb. in all.

Tin—The price for this metal declined owing to continued lack of demand. Deliveries for July will be large, explaining to some extent the recent absence of buying.

Exports of tin from the Federated Malay States in June were 4048 long tons. For the half-year ended June 30 the totals were 24,902 tons in 1914, and 23,318 in 1915; a decrease of 584 tons this year.

Lead—The same conditions continued to exist as we reported last week. Producers firmly maintained their price of 5.75c., New York, and did some business thereat, while second-hands sold lead as low as 5.50c., New York. If a manufacturer desires to buy he is apt to find that he must go to the producers and pay their price, while if a trader has to sell, he is obliged to take what he can get. In other words, the lead market has been extremely narrow. There appear to be some signs of revival of buying for ammunition, and there are no discoverable signs of weakening on the part of the producers. On the contrary, the opinion is expressed that the maintenance of a price of 5.75c. is necessary in order to keep production up to the required level, which is considered to be necessary in view of the continued idleness of one of the large Coeur d'Alene producers. There is no reason to believe that the stocks of lead in the hands of smelters and refiners are increasing.

Spelter—The price declined from day to day upon offerings by smelters who were anxious to sell and consumers who had overbought their requirements and were desirous of disposing of their surplus. There seems to be considerable tonnage of spelter available for prompt delivery, and the difference in the prices for such and for fourth-quarter contracts is narrowing. The reported transactions for the week amounted to several thousands of tons, the aggregate being larger than in the previous week. Galvanizers were buyers to a small extent. A small tonnage was reported sold for export at the beginning of the week, but later there were no buyers either in England or France. Brass special spelter was sold at a relatively small premium over prime Western, transactions being reported at 19@19½c., including prompt delivery.

Zinc Sheets are strong, base price $27 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras charged. The demand is steady and business is good.

Exports from Baltimore for the week included 254,580 lb. zinc dross to Liverpool.

Other Metals

NEW YORK—July 28

Aluminum is rather quiet though there is a fair amount of business forward. Prices are just a shade easier at 31@33c. per lb. for No. 1 ingots, New York.

DAILY PRICES OF METALS IN NEW YORK

			Copper	Tin	Lead		Zinc
July	Sterling Exchange	Silver, Cts. per Oz.	Electrolytic, Cts. per Lb.	Spot, Cts. per Lb.	New York, Cts. per Lb.	St. Louis, Cts. per Lb.	St. Louis, Cts. per Lb.

*Nominal.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are; St. Louis-New York, 17c.; St. Louis-Chicago, 6 3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

		Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
July	Silver	Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts. per Lb.
22	22 7/16	75¼	76¼	90½	19 27	165	162	24½	5 24	96	20 44
23	22½	74½	75⅝	89½	19 05	162½	160¼	24½	5 22	96	20 44
24	22 7/16	...	...	...	...	...	...	...	...	...	...
26	22½	71½	72⅞	88½	18 85	161½	159½	24½	5 22	93½	19 91
27	22½	72¼	73¾	87½	18 64	161¼	160	24⅜	5.19	92½	19 70
28	22⅜	72	73¼	87½	18 64	160¾	160	24⅜	5.19	92½	19 70

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £ 15. = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Antimony—The market has been quiet with a small business reported, and buying rather slow. Ordinary brands bring 35½@37c. per lb. Cookson's is held nominally at 48c. per lb., but is being small.

Quicksilver—The market is strong but with less active demand than there has been. Prices show no material change. New York quotations are $92@94 per flask of 75 lb. for large lots, while $95@99 is paid for small orders. San Francisco reports by telegraph $92.50@95 per flask, on a quiet market. London price is £18 5s. per flask, with £18 2s. 6d. quoted from second hands.

Nickel is steady and unchanged at 40@50c. per lb. for ordinary forms, according to size of order. Electrolytic 3c. per lb. higher.

Minor Metals—Current sales of **Bismuth** are at $2.75@3 per lb. New York. The London price is quoted at 10s., or $2.40 per lb. there—**Cadmium** is quoted at 6s., or $1.44 per lb. in London; $1.50 per lb., New York.—**Tellurium** is reported sold at 80s., or $19.20 per lb. in London.—**Selenium** is quoted at $2@3 per lb. New York for larger quantities; $4.50@5 for retail lots.

British Imports and Exports of Metals other than iron and steel, six months ended June 30, in long tons:

	Imports		Exports	
Metals:	1914	1915	1914	1915
Copper	85,321	115,806	32,282	16,931
Tin	24,013	22,229	22,241	22,867
Lead	110,101	134,723	27,227	30,692
Zinc	65,266	52,163	5,673	1,543
Quicksilver	1,178	792	401	151
Minor metals	4,822	2,561	13,732	9,531
Ores, etc.				
Tin concentrates	19,799	25,158	.....	.....
Pyrites	419,493	493,300	.....	.....

Copper imports include metallic contents of ore, matte, etc. Exports include reëxports of foreign material.

Gold, Silver and Platinum

NEW YORK—July 28

Gold Imports in Great Britain six months ended June 30 were £6,010,211; exports, £5,530,544; excess of imports, £479,667. Comparisons with 1914 are of no use, as imports from South Africa, Australia and India have ceased, the gold produced being held in those countries subject to order, to avoid shipping risks.

Platinum shows slightly more demand with some signs of increased activity, but no material change in the market. The quotations continue about $37@39 per oz. for refined platinum and $41@44 per oz. for hard metal.

Silver—The tone of the market is without animation. London advises, if it were not for the scantiness of supplies, it would be difficult to maintain prices. At the same time a revival in demand would cause a rally in prices.

The London quotation for silver on July 16 was 22⅝d., instead of 22½d. as given in our table. The error was caused by a mistake in transmission.

Silver shipments from London to the East Jan. 1 to July 14, as reported by Messrs. Pixley & Abell:

	1914	1915	Changes
India	£3,946,000	£2,800,000	D. £1,146,000
China	40,000	5,000	D. 35,000
Total	£3,986,000	£2,805,000	D. £1,181,000

Imports of Silver in Great Britain six months ended June 30 were valued at £5,725,215; exports, £4,280,369; excess of imports £1,444,846, which compares with an excess of exports of £1,452,529 in 1914. Of the imports this year £4,171,755 were from the United States.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—July 24

The base price this week was lowered to $105 per ton for 60% zinc ore. The base price paid for 80% lead ore was $60 per ton.

SHIPMENTS WEEK ENDED JULY 24

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	3,721,500	89,700	439,480
Year	105,762,220	4,083,160	15,201,650

Shipped during week to separating plants, 4,267,300 lb. zinc ore.

JOPLIN, MO.—July 24

Blende, high price $117.50; base per ton of 60% zinc, premium ore $115; medium $105@95, and $90 was as low as was paid for the lowest grades in carlots. Calamine base per ton of 40% zinc, $56@60 in ton and up to $80 in carlots. Average price, all grades of zinc, $107.06 per ton. Lead, high price $61.50; base, $60 per ton of 80% metal content; average, all grades of zinc, $59.59 per ton.

SHIPMENTS, WEEK ENDED JULY 24

	Blende	Calamine	Lead	Values
Totals this week	11,266,740	715,980	1,554,990	$687,730
Totals this year	322,177,000	27,801,370	48,763,180	13,790,670

Blende value, the week, $618,580; 30 weeks, $11,901,190.

Calamine value, the week, $22,820; 30 weeks, $600,290.

Lead value, the week, $46,330; 30 weeks, $1,289,190.

Mining operations have resumed an entirely normal stage again, and the shipment is above an average one. The two weeks of the strike gave the miners a rest and they returned to work in better spirits and with more action than had been displayed for two months.

Iron Trade Review

NEW YORK—July 28

The iron and steel markets continue to advance, though this month is usually about the dullest of the year. Domestic as well as export orders are in evidence.

A good increase is evident in structural steel, which has been rather slow. New orders are being closed and there is an evident increase in building activity.

There has been enlarged inquiry for foundry and basic pig iron, and prices generally are firmer, even showing some increase.

Imports at Baltimore for the week included 1403 tons ferromanganese from Liverpool and 9700 tons manganese ore from Brazil.

Exports from Baltimore for the past week included 12,021,292 lb. miscellaneous iron and steel products to Great Britain.

The United States Steel Corporation reports for the quarter ended June 30 that net earnings, after deducting expenses for renewals, repairs, maintenance of plants, interest on bonds and fixed charges of subsidiary companies, were as follows:

	1914	1915
April	$6,920,879	$7,286,409
May	6,845,823	9,320,576
June	6,690,894	11,343,070
Quarter	$20,457,596	$29,950,055
Depreciation, reserve fund, etc.	.....	$6,031,013
Interest and sinking fund	.....	7,346,478
Dividend, 1¼% on preferred stock	.....	6,304,919
Total charges		$19,682,410
Surplus for the quarter		$8,267,615

No dividend was declared on the common stock. The increase in net earnings over the quarter ended Mar. 31 was $15,492,246, showing the great improvement in the steel trade during the past three months. For the half-year ended June 30 the net earnings amounted to $38,451,977 in 1914 and $40,407,864 in 1915, an increase of $1,955,887. The large earnings of May and June more than offset the heavy decrease in the first quarter as compared with 1914. The surplus shown was made notwithstanding an increase of $1,800,000 in the depreciation and replacement funds.

Foreign Iron Trade of Great Britain, six months ended June 30, as valued by the Board of Trade returns:

	Exports	Imports	Excess
Iron and steel	£17,771,936	£4,177,263 Exp.	£13,594,733
Machinery, hardware, etc	14,869,771	7,140 804 Exp.	7,728,967
Totals	£32,641,767	£11,318,067 Exp.	£21,323,700
Totals, 1914	54,574,872	16,221,953 Exp.	38,352,919

Quantities of iron and steel exported, 2,376,264 tons in 1914 and 1,448,502 in 1915; imported, 1,170,989 tons in 1914 and 511,012 this year.

The British Iron Market is reported quiet, with fair production. Some current quotations for pig iron are: East Coast hematite (bessemer) pig, $24 per ton; Cleveland No. 3, $16.32. Some prices for finished iron and steel are: Steel plates, $48 per ton; steel angles, $46.80; iron ship plates, $48; iron ship angles, $52.60; iron bars, $52.80, less 2½%; steel rails, $42 per ton, net.

PITTSBURGH—July 27

The steel mills are rapidly filling up with orders. In bars the earliest delivery promise on new specifications is about six weeks, while on some sizes the time is much longer. Even plates and shapes, the demand for which has been relatively light, are not being promised earlier than Sept. 1 by the Carnegie Steel Co. In wire the demand is well above normal, in blue annealed it is quite heavy while in sheets it is

improving. Galvanized sheets have declined to 4.25c., but merely on account of the decline in spelter.

Openhearth steel has become scarce, although the full capacity is productive. Full employment of bessemer capacity depends upon whether enough buyers will be content to accept that description of steel, prospects being that they will have to lay aside their scruples.

A considerable part of the steel buying of the past fortnight has been due to buyers endeavoring to lay in stocks since they can no longer depend upon practically immediate shipments from mill and there is every reason to expect this demand to set the mills much farther behind in deliveries, so that it is universally believed the steel industry is booked for capacity operations for a period of months at least, and probably of years.

The Steel Corporation's earnings in the second quarter, announced this afternoon at $27,950,055, prove slightly larger than was expected in Pittsburgh steel circles. Earnings not far from $35,000,000 are now expected for the current quarter.

Steel bars are strong at 1.30c., with plates and shapes at 1.25c. to 1.30c. Sheets are 4.25c. for galvanized, 1.75c. to 1.80c. for black and 1.35c. to 1.40c for blue annealed

Pig Iron—The local market is quieter again, but is regarded as very firm. Sales of bessemer of 1500 tons and 450 tons respectively are reported at $14.25, Valley, an advance of 25c. over the market quoted a week ago. We now quote: Bessemer, $14.25; basic, $13; foundry and malleable, $12.75@13; gray forge, $12.50@12.75, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—Sales of prompt continue to be made at $100@105, while the contract market is $100, Baltimore, with not much activity.

Steel—Quotations on openhearth steel are largely nominal, while bessemer quotations have not been seriously tested, the current demand being almost wholly for openhearth. We quote: Bessemer billets, $21; bessemer sheet bars, $21.50; openhearth billets, $22; openhearth sheet bars, $22.50, f.o.b. maker's mill, Youngstown, and $1 higher delivered Pittsburgh. Rods are firm and scarce at $26, Pittsburgh.

United States Foreign Trade in iron and steel and manufactures thereof is valued by the Department of Commerce as below for the five months ended May 31:

	1914	1915	Changes
Exports	$84,151,409	$107,348,938	I. $13,197,529
Imports	13,142,197	8,046,871	D. 5,095,326
Excess, exports	$81,009,212	$99,302,067	I. $18,292,855

The increase in exports this year as compared with 1914 was $4,863,080 in March and $6,802,567 in April. In the month of May the quantity of those exports which are reported by weight was 246,530 tons, against 134,605 tons in May, 1914. The larger increases were in billets, bars, sheets and wire.

FOREIGN IRON

Pig Iron Production in Germany, as reported by the German Iron & Steel Union, was 985,968 metric tons, which is 47,289 tons more than in April, and 621,243 tons less than in May, 1914. For the five months ended May 31 the total was 7,756,901 tons in 1914, and 4,540,841 tons in 1915; a decrease of 3,216,060 tons, or 41.5%, this year.

German Steel Production in April is reported by the German Iron & Steel Union at 1,012,334 metric tons, which is 85,977 tons less than in March. For the four months ended Apr. 30 the make was:

	Basic	Acid	Total
Converter ingots	2,049,649	49,650	2,099,289
Openhearth ingots	1,676,394	64,717	1,701,111
Direct castings	120,199	34,485	154,675
Crucible steel		33,015	33,015
Electric steel		32,498	32,498
Total	3,846,223	214,365	4,020,588
Total, 1914	5,983,589	248,749	6,232,329

The total decrease this year, as compared with 1914 was 2,211,741 tons, or 35.5%. There are 234 steel works reported in operation this year.

IRON ORE

Eastern Pennsylvania furnaces have purchased some trial lots of the off-grade Lake Superior ores which have been offered recently at attractive prices. These purchases have consisted chiefly of an old-range nonbessemer of 48% iron and 13% silicon content, which have been taken at about 7.1c. per unit of iron delivered to the furnaces, or on the basis of about $1.80 at lower lake ports.

Imports and Exports of Iron Ore in the United States, five months ended May 31, in long tons:

	1914	1915	Changes
Imports	520,398	432,766	D. 87,632
Exports	15,396	22,290	D. 137,106

Imports of manganese ore were 112,120 tons in 1914 and 27,137 in 1915; decrease, 84,983 tons.

French Imports and Exports of iron ore for two years, in metric tons.

	1913	1914	Changes
Imports	1,410,424	698,319	D. 712,105
Exports	10,066,627	4,767,194	D. 5,299,433

The heavy decreases shown were due entirely to the war, which has closed the most productive iron-ore mines and a number of furnaces.

Imports of manganese ore were 258,929 tons in 1913, and 153,449 in 1914; decrease, 105,480 tons.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 371,144 short tons; shipments, 365,615 tons. Production in the Greensburg and upper Connellsville districts was 42,067 tons.

Connellsville—The prompt furnace coke market has been unable to stand the recent increase in production, coupled with orders from five consumers to curtail shipments on contracts temporarily, and the market has broken from $1.70 to $1.60, with no takers at the lower price. There are no negotiations of importance for contract coke. We quote: Prompt furnace, $1.60; contracts over third quarter, $1.75; contracts over second half, $1.85@2; prompt foundry, $2.10@2.40; contract foundry, $2.25@2.60, per net ton at ovens.

Coal and Coke Tonnage, Pennsylvania R.R. lines east of Pittsburgh and Erie, six months ended June 30, in short tons:

	1914	1915	Changes
Anthracite	5,560,680	5,423,467	D. 137,213
Bituminous	21,973,572	20,261,777	D. 1,711,795
Coke	5,196,084	4,998,919	D. 197,165
Totals	32,730,336	30,684,163	D. 2,046,173

The total tonnage for the month of June this year was 5,498,232, an increase of 181,576 tons over June, 1914; the gain being chiefly in coke.

Foreign Fuel Trade of the United States, five months ended May 31, as reported by the Department of Commerce in long tons:

	Exports		Imports	
	1914	1915	1914	191
Anthracite	1,439,402	1,371,955	4,291	222
Bituminous	4,564,531	4,427,832	567,173	604,337
Coke	305,611	242,151	38,387	14,900
Bunker coal	3,157,120	2,963,277		
Totals	9,466,664	9,005,215	609,851	619,459

The bunker coal, or coal furnished to steamers in foreign trade, is practically all bituminous. Exports of bituminous coal in May increased 320,464 tons, chiefly in shipments to Brazil and Argentine.

Chemicals

NEW YORK—July 28

The general market is quiet; indeed no great activity is to be expected at this season, when midsummer dullness is the rule.

Arsenic—Very little is doing in this article. The market is dull, but not especially weak. Prices are unchanged at about $4 per 100 lb. for both spot and futures.

Copper Sulphate—There is nothing new. On a quiet market prices are steady. The current quotations are $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller parcels.

Nitrate of Soda—The market is fair for the season, and is steady, with prices unchanged. Quotations are 2.35c. per lb. for spot and for all positions this year.

Pyrites—Imports at Baltimore for the week included 4[illegible] tons pyrites from Huelva, Spain.

NEW CALEDONIA

Exports of minerals from New Caledonia for four [illegible] past have been as follows, in metric tons:

Ores:	1911	1912	1913	1 [illegible]
Nickel	120,059	74,312	93,190	[illegible]
Cobalt	[illegible]	[illegible]	[illegible]	[illegible]
Chrome	32,806	51,516	63,370	71 [illegible]
Mattes:				
Nickel	2,993	5,098	5,893	[illegible]
Cobalt	[illegible]	[illegible]	[illegible]	25

In 1914 the exports included 305 tons nickel matte and 25,102 tons chrome ore to the United States direct

VOLUME 100 AUGUST 7, 1915 NUMBER 6

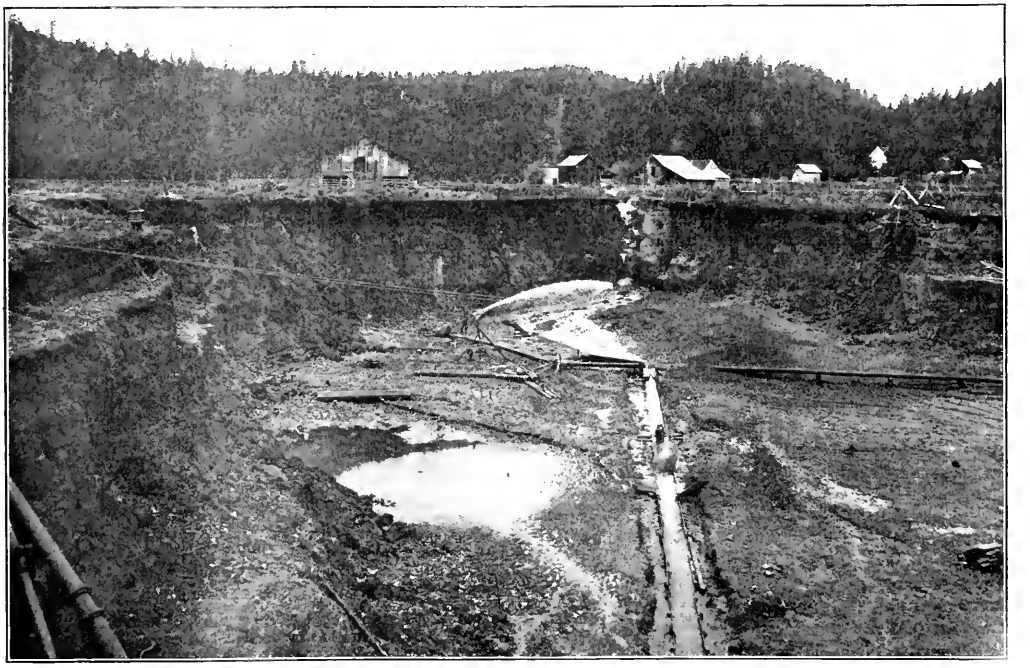
Hydraulicking at Waldo, Ore.

By W. H. Wright*

SYNOPSIS—The Waldo placer field is in southern Oregon, only seven miles from the California line. Hydraulic elevators are required for most of the deposits on account of lack of grade for disposal of tailings. Some interesting details of the operations and equipments are given. Besides the gold, a little platinum is recovered.

The visitor to the placer fields of the Waldo district, Oregon, is at once impressed with the importance of the part played by the hydraulic elevator in mining operations. In March, 1915, three mines were active—the Logan, the Osgood and the Deep Gravel. Waldo district is situated in the southwestern part of Josephine County, seven miles north of the Oregon-California line and 40 miles west of Grants Pass, a station on the Southern Pacific R.R. It is reached by daily automobile stage running between Grants Pass, Ore., and Crescent City, Calif. The town of Waldo, from which the district takes its name, is situated in the center of the placer field 1500 ft. above sea level.

The commonly accepted story of the first discovery of gold in the district is that in 1851 a party of sailors, deserting their ship, made their way inland and found gold in a ravine, which thereafter took the name of Sailors Gulch. This ravine heads on the east side of the ridge on which the Osgood mine is situated. The usual rush followed and the surrounding territory was thoroughly worked as far as the depth of gravel and crude methods would permit. Later, ditches were dug and water brought in from a distance of 3 to 11 miles for hydraulicking the deeper gravels.



PIPING IN THE PIT OF THE LOGAN MINE, WALDO, ORE.

Hydraulic elevators are necessary at most of the mines in this district, the grade of the bedrock being insufficient to dispose of the tailings

*Mining engineer, 5494 College Ave., Oakland, Calif.

For the most part the bedrock at the Logan and the Deep Gravel mines is Cretaceous sandstone and conglomerate, but some serpentine occurs at the upper end of the Deep Gravel mine. The conglomerate is composed of rotten, rounded pebbles and boulders of greenstone, with some granitic rocks. In places it has a reddish color, but the freshly exposed portions observed have a purplish tint. The conglomerate is gold bearing and is soft enough to be piped, but with the exception of the Osgood mine none of it is rich enough for profitable hydraulicking. This conglomerate is of marine origin, having been deposited about the shores of a Cretaceous island and is considered[1] the source of the later gravels being washed at the Logan and the Deep Gravel mines.

The Logan mine, operated by J. T. Logan, is situated one-half mile north of Waldo. It consists of 1000 acres and has an average depth of 35 ft. The gravel is easily piped and is all put through a Joshua Hendy hydraulic elevator, the largest boulders being 6 in. diameter. The first work done on this mine was through a race one mile north of the present workings. Then a pit was opened on French Flat, not far from the schoolhouse and just east of the pit now being worked. The tailings were elevated and stacked with giants. Tailings from the present pit are deposited in the old pit and two giants are employed in the distribution. Mr. Logan purposes reclaiming the old workings for farming as the work progresses.

Water for the present work is obtained from the east fork of Illinois River, across the state line in Del Norte County, California. One ditch, 11 miles long, with capacity of 13 cu.ft. per sec., gives a working head of 340 ft. A second ditch, 5 miles long, supplies 33 cu.ft. per sec., at a working head of 125 ft. The first ditch is used for the elevator exclusively. The second ditch supplies the four giants, two in the pit and two on the tailings dump and the top lift of the elevator. The two giants in the pit are used to wash down the bank. The gravel is carried by a bedrock sluice to the hydraulic elevator which raises it to a height of 49 ft. and into a flume which passes it into the old pit. Accompanying illustrations plainly show the method of working at the Logan, and interesting features at the Osgood and the Deep Gravel.

Details of the Logan Mine Equipment

The bedrock sluice is 200 ft. long and 30 in. wide. No riffles are used. High-carbon steel plates, ½x20x30 in., are placed on 2x4-in. wooden crosspieces standing on edge. The crosspieces are usually set 2 in. in from the ends of the plates and as the plates are placed 1½ in. apart there is a clear space of 4x5½ in. under the ends of the plates. Occasionally the crosspieces are placed at the center of the plate only. This arrangement is varied at intervals by laying the long dimension of the plate lengthwise of the sluice, giving a 5-in. space each side of the plate. The plates greatly facilitate the passage of the sand and gravel through the sluice. The wear is slight. No other gold-saving device is used here, but Mr. Logan states that 93% of the gold recovery is made in the sluice.

The elevator has the following dimensions: Entrance section, 20 in.; throat, 9 in.; inside diameter of upraise pipe to top lift, 13 in.; inside diameter of upraise pipe from lift to flume, 15 in. The water for the top lift comes into the elevator through a needle valve about 10 ft. below the discharge. It is used only when there is a scarcity of water in the high-line ditch. The elevator handles from 15,000 to 30,000 cu.yd. per month, the grade of the bedrock sluice governing the yardage. The flume into which the elevator discharges is 40 in. wide and 340 ft. long. In this flume are 200 ft. of Hungarian riffles made up of ½x2x2-in. angle iron; then 40 ft. of 8-lb. rails with ⅜-in. steel plates for the remaining 100 ft. Besides the four giants and elevator mentioned there is a water lift used to keep the pit dry when no piping is being done. Altogether, there are 1500 ft. of pipe, ranging in diameter from 15 in. to 24 in., of 14- and 16-in. gage.

Water is taken from the pipe lines to generate the electricity used in lighting the mine and buildings. It also furnishes power for various electrical appliances, such as the blower for the bullion furnaces and electric range and heaters in the residence. During the idle months the water is used for irrigating the farming land.

While the gold has a fineness of 975 it is rusty and does not amalgamate easily, that observed having a purplish coating of oxides. However, it is coarse and is not hard to save. A considerable amount of platinum is obtained. The black sand is concentrated by working it over with a square-pointed shovel in a smooth, wide sluice, with a flat grade and a small amount of water. The concentrate is shipped to a smeltery. The operating expenses are between $600 and $700 per month and the cleanups, including gold and platinum, run between $8000 and $10,000 per month. Eight months is the average length of the season.

Elevating Not Necessary at Osgood Mine

The Osgood mine is situated about one mile southeast of Waldo on a ridge running north and south which forms the divide between the east and west forks of the Illinois River. The summit of the ridge is about 300 ft. above the east fork and about one mile distant. The gravel that is being hydraulicked is Cretaceous conglomerate, which caps the summit of the ridge. The conglomerate lies on greenstone which is very uneven. It is decomposed, fissured and veined and has a decided purple color due to iron oxides. The property embraces an area of 636 acres. It is being operated under lease by J. T. Logan.

Piping has been done for 1000 ft. along the ridge and at the present site a width of over 100 ft. is exposed. The present bank is 90 ft. high. The deposit is cemented, but gives no great difficulty in piping. Water at 125-ft. head is supplied by a ditch 11 miles in length, from the east branch of the Illinois River. The mine is equipped with one No. 2 and one No. 3 giant; 1500 ft. of pipe 11 to 15 in. diameter; and 300 ft. of 40-in. flume. Steel plates are used as at the Logan mine, but are separated at intervals by sections of Hungarian riffles made of ¼x2x2-in. angle irons and steel rails. The gravel is piped directly into the flume, the great amount of fall giving no occasion for elevating the gravel. The gold content runs between 12c. and 15c. per cu.yd. One feature of this mine is that the gold is very black. Mr. Logan reports great difficulty in saving it, which, however, he is successfully doing. The gold fineness is 930.

[1]Diller, J. S., Bulletin 546, United States Geological Survey.

In Frye Gulch, which heads on the west side of the ridge near the Osgood mine, A. H. Gunnell, of Grants Pass, and associates are doing some prospecting by sinking shafts with the view of developing dredging ground. The work was just starting at the time of my visit in March, 1915, so that no results were obtainable.

The Deep Gravel Mine Sometimes Has Water Enough to Work Entire Year

The Deep Gravel mine, owned by W. J. Wimer of Waldo and A. E. Reames of Medford, Ore., under the name of Deep Gravel Mining Co., is worked under lease by H. L. Herzinger. The property contains 530 acres, of which two-thirds is mining ground. Forty acres have been worked since Mr. Wimer became the owner in 1873. It extends from the west fork of the Illinois River to within half a mile of Waldo, and is situated northwest of the town and separated from the Logan mine by a low ridge. The depth of the gravel to bedrock varies from 12 ft. at the upper end of the property to 120 ft. at the lower end on the Illinois River.

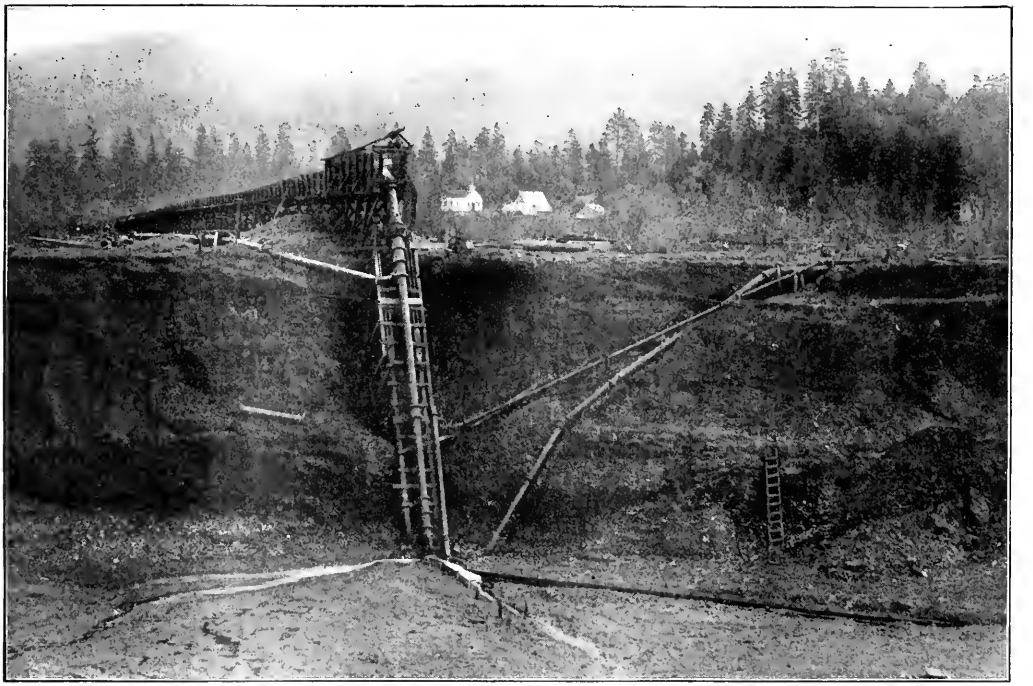
The greatest depth the ground has been worked is 80 ft., and to do that it was necessary to elevate the gravel 49 ft. That there is some rich ground on bedrock has been proved by two shafts of 122 ft. and 120 ft. The output since 1878 has been more than $350,000 at a cost of $150,000. It is said that much of the cost was due to litigation, which has now been settled.

Water is obtained from the east fork of the Illinois River by a ditch 3 miles long, which carries 2800 in. of water and gives a working head of 140 ft. to 202 ft., depending on the part of the property being worked. Another ditch gives 500 in. of water. For six months in the year the total amount of water available is 10,000 in. Mr. Wimer states that some years it is possible to operate the full 12 months.

Equipment of the Deep Gravel Mine

The property is equipped with a No. 2 hydraulic elevator; a sand and gravel elevator; water lift; two No. 1, one No. 2, and one No. 4 giants; 80 ft. of 40-in. flume with 50 ft. of undercurrent; 120 ft. of bedrock sluice 22 in. wide; and 5000 ft. of pipe from 11 to 24 in. in diameter. A tailrace 7000 ft. long discharges into the west fork of the Illinois River.

The riffles in the bedrock sluice are made of 2x4-in. lumber, in sets of six, and connected at each end by strap-iron-covered cleats. The riffles are 5 ft. long and are placed lengthwise of the sluice with the 2-in. side uppermost. This side is sharply beveled and covered with $\frac{3}{16}$x2-in. strap iron. The bevels alternate to the right and left on the successive sets in order to prevent scouring currents. In the first 20 ft. of flume 12x12-in. blocks are placed, which are followed by 30 ft. of heavy pole riffles. At the end of the poles the undercurrent runs off at right angles to the flume. The screen for the undercurrent is formed by 8-lb. rails set with $1\frac{1}{4}$-in. openings. From the undercurrent to the end of the



RAISING GRAVEL TO THE FLUME WITH HYDRAULIC ELEVATOR, LOGAN MINE, WALDO, ORE.

Note the auxiliary lift about 10 ft. below the top of the elevator. This is only used when the supply of water for the main line is low. The elevator handles from 15,000 to 30,000 cu.yd. of gravel per month, the grade of the bedrock sluice governing the yardage.

ne, a distance of 50 ft., pole riffles are used. Hungarian riffles are used in the undercurrent, the size of the iron being ¼x2x2-in. angle.

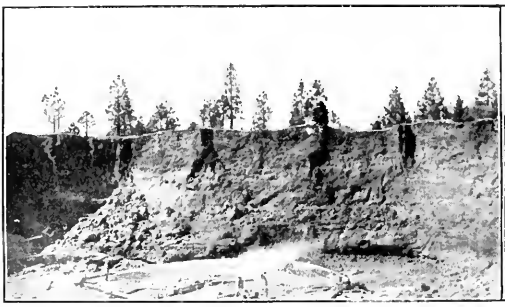
The system of mining is essentially the same as that employed at the Logan mine. The gravel is much more compact, however. The bank is difficult to pipe, but readily crumbles up under weather and moisture. A small charge of powder will loosen a large area. The two large giants are set up on the bedrock at the bottom of the pit. They wash the gravel into the bedrock sluice, from the end of which the elevator raises it 27 ft. to the flume. The coarse material is carried through the flume into the race, while the fines pass through the screen into the undercurrent. At the present point of operations the bank is about 45 ft. The elevation at the Wimer mine is 65 ft. lower than at the Logan. By tunneling the ridge the two properties could be worked conjointly.

The gold is coarse and bright. With the gold some platinum is also saved. The largest amount of platinum recovered in one year was 20 oz. and Mr. Wimer estimates that 120 oz. was lost in the cleanup. Mr. Wimer has made a special study of the problem of saving platinum and was awarded the highest honors at the Lewis & Clark Exposition for his exhibit. He found in his experiments that only one-seventh of the platinum was recovered by the ordinary cleanup methods. He increased the recovery of platinum sevenfold by simply using great care in handling the cleanup. When the gold and amalgam is picked up no mercury leaves the sand is collected with it. The amalgam is separated from the sand by ordinary panning and the pannings saved. These are worked down by a careful forward-and-back motion of the pan. It is found that the whirling motion ordinarily given the pan in washing the sand was responsible for a great part of the loss, as was also the custom of washing all the sand possible from the amalgam when picking it up in the sluices.

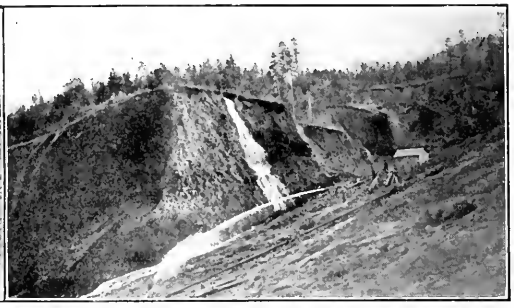
The platinum occurs in small, bright scales, but some nuggets are found. Mr. Wimer exhibited one the size of a large wheat grain and stated that he had found one as large as a pea. An analysis of the platinum cleanup gave the following results: Gold, 0.4%; platinum, 70.5%; osmiridium, 20.5%.

Mineral Production of Hungary in 1913

The mineral production of Hungary in 1913, as officially reported, was as follows (*Montanistische Rundschau*, July 1, 1915)—the items, except those of gold and silver, being given in metric tons, and arranged in order of descending values: Lignite, 8,801,166; pig iron, 608,966; salt, 301,806; coal, 1,058,878; gold, 2924 kg.; iron ore for export, 551,734; coke, 160,073; briquettes, 117,186; pyrites, 106,629; silver, 8696 kg.; antimony, crude and refined, 1048; copper, 404; ammonium sulphate, 2122; lead, 1136; copper cement and ore, 1679; quicksilver, 89; coal tar, 7193; manganese ore, 19,006; petroleum, 2105; silver ore, 204; zinc ore and residue, 407; alum stone, 1792; sulphur, 41; sulphuric acid, 555; antimony ore, 28.



Piping in the pit of the Deep Gravel Mine at Waldo. See view of sluice and elevator below



The Osgood is the only mine at Waldo having sufficient grade to dispense with elevators for disposing of tailings

GIANTS DISTRIBUTING TAILINGS AT THE END OF THE LOGAN FLUME

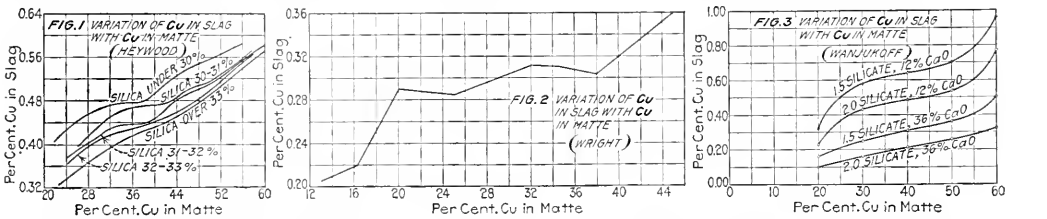
Metal Loss in Copper Slags--I

By Frank E. Lathe*

SYNOPSIS—The first of three articles discussing copper losses in slags. The introductory article presents a résumé of the most important literature on the subject and diagrams showing the variation of copper in slags under different conditions.

In his endeavor to reduce slag losses to the lowest possible point the metallurgist often finds himself limited by local conditions. Thus in the early days of the Southwest, in smelting oxidized copper ores with high-priced coke, it was sometimes found economical to waste in the slag more copper than a few of our present-day companies find in the ore itself. Even now, in districts where cheap fluxes are not available or other conditions are adverse, valuable metals in quantities which could be saved are allowed to pass into the slag; the metallurgist—perhaps an ardent conservationist—consoling himself for the sacrifice of his ideals with the thought that more dollars are nevertheless going into the pockets of shareholders.

Until recently, little was known concerning the chemical combinations of the copper, gold and silver lost in copper smelting, and the methods adopted to keep these losses down have not been discussed as fully as their importance deserves. In this paper I shall review some of the more recent articles on slag losses, give in detail the results of my own investigations and conclude with a general consideration of the whole subject.



VARIATION OF COPPER IN SLAG WITH TENOR OF MATTE—AFTER HEYWOOD, WRIGHT AND WANJUKOFF

Review of Slag Literature

William A. Heywood (*Engineering and Mining Journal*, 1904, Vol. 77, p. 395, and "Pyrite Smelting," p. 231—Mr. Heywood, relating his experience at the Tennessee Copper Co.'s smeltery, showed graphically the effect of variations in the composition of the slag and in the grade of matte on the percentage of copper lost. He plotted the copper content of 2590 slags, representing the average of two furnaces for a period of 2½ years, against the copper content of the matte for curves of (1) under 30% SiO_2 in the slag (2) 30-31%, (3) 31-32%, (4) 32-33%, (5) over 33%. These curves (Fig. 1) show an increase of slag loss with the grade of matte, and also indicate the decidedly lower losses with increasing acidity of the slag. Even though the higher percentage of SiO_2 was due to the addition of barren quartz to the charge, Mr. Heywood found a decrease in the total amount of copper lost except with mattes of more than 50%, when the totals were approximately equal. The average decrease of copper appears to be about 1% of the increase in SiO_2.

Lewis T. Wright (*Trans. of A. I. M. E.*, 1909, Vol. 40, p. 492)—Mr. Wright expressed his disbelief in the common theory that all the copper in slags existed as prills of matte, giving several reasons:

1. That matte did not separate from slag kept in the molten state even for a long time.

2. That no concentration of the valuable metals was possible by elutriation after fine grinding.

3. That the proportions of gold, silver and copper in slag were often different from those in the accompanying matte. This was illustrated by four examples from Mr. Wright's experience. The amount of gold in his slags varied from 31-69% (average 58%) of what might be expected if all the copper in the slag were present as mechanically suspended matte, while for silver the corresponding amounts were 76-93% (average 81%). From these data Mr. Wright concluded that probably a part of the matte was chemically dissolved in the slag; hence copper sulphide, presumably more soluble than gold or silver, was found there in greater proportion than those metals.

4. He then plotted a curve (Fig. 2) of the copper in slag against that in matte, as found in his experience, showing between 15% and 45% matte, an average increase of 0.005% copper in the slag for each per cent. of copper in the matte. He remarked that the curve showed depressions at 25% and 37%. He thought that if metallic copper separated from matte in quantities increasing with the grade of the latter, the tendency of this copper to settle out might prevent the observed increase of copper in the slag with the higher mattes.

5. His experience also showed that the copper in slags decreased about 0.01% for each increase of 1% in the silica content. This he thought indicative of solution rather than mechanical suspension of matte.

6. In conclusion, Mr. Wright stated that if a slag made with a matte of certain gold and silver content were afterwards left in contact with a different matte it would itself assume different metal ratios to correspond to the changed conditions. This fact he had made use of to great advantage in smelting, and in explanation of it he suggested that the matte and slag were both acting as solvents, dividing the metals between them.

*Chief chemist, Granby Consolidated Mining, Smelting & Power Co., Ltd., Grand Forks, B. C., Can.

J. Parke Channing (*Trans. of A. I. M. E.*, 1910, Vol. 41, p. 485)—Commenting on Mr. Wright's paper, Mr. Channing stated that he had discussed this question with J. E. McAllister, and they were both of the opinion that a considerable part of the copper entered the slag as oxide or silicate and not as sulphide, either suspended or dissolved. This theory appeared to explain why the amounts of gold and silver Mr. Wright had found in the slag were smaller than the calculated contents. In support of it Mr. Channing stated that when they were using an oxidized charge (roasted ore) at the Tennessee Copper Co.'s smeltery, the slags contained 0.5% Cu, as against 0.3% in pyritic smelting at the same plant. (It was not stated whether the grade of matte and composition of the slag remained the same in pyritic smelting.)

C. A. Ueberlein (*Engineering and Mining Journal*, 1910, Vol. 89, p. 617)—Mr. Ueberlein, recounted his experience in blowing in the furnace of the Maine & Nebraska Mining Co., using an ore with only 0.3% copper, but carrying considerable gold and silver. The slags produced averaged about 0.09% copper, or a recovery of 78%, while that of the gold was nearly 96%, the silver being somewhat lower. (This gives the ratio of gold to copper about 18% of that calculated from the matte, as against 58% found by Mr. Wright.)

F. A. Sundt (*Engineering and Mining Journal*, 1910, Vol. 89, p. 1097)—Mr. Sundt gave the results of his work at different smelteries in Chile, and from these he concluded that the percentage of copper in a slag depended, in part at least, on that in the charge. Rich charges in general gave slags carrying more copper, though percentage recoveries were better. He also derived a formula for finding the recovery efficiency of smelting under various conditions.

Determining Oxide Copper in Slag

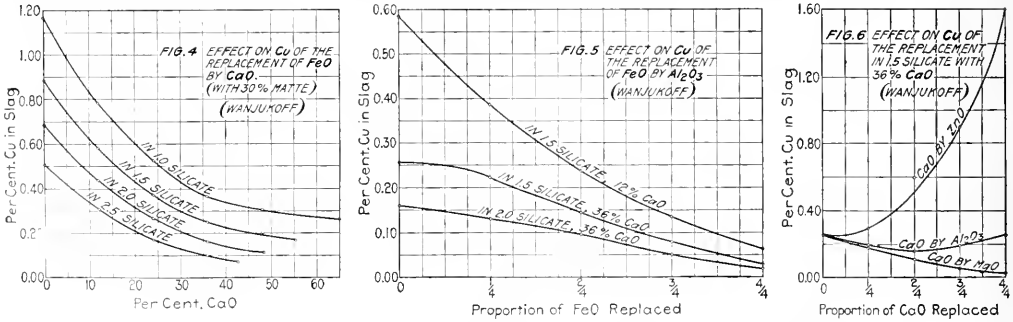
Thomas Kiddie (*Journal of C. M. I.*, 1911, Vol. 14, p. 487)—Mr. Kiddie stated the results of some laboratory experiments performed under his direction. By actual determination of the oxide of copper present he learned the percentages formed under normal conditions. The laboratory method (private communication) was as follows:

A sample of finely ground slag was digested at 80° C. with 5% H_2SO_4, two treatments being desirable; the insoluble was filtered and washed, and copper was determined in the filtrate by electrolysis. The residue was then treated with strong HNO_3 and H_2SO_4, and copper also determined in that solution by electrolysis. The former result represented all the copper present as CuO and half of it as Cu_2O, according to the equations:

$$CuO + H_2SO_4 = CuSO_4 + H_2O$$
$$Cu_2O + H_2SO_4 = CuSO_4 + H_2O + Cu$$

The percentage obtained by HNO_3 and H_2SO_4 (sulphide) was checked by determining the total copper in another portion by usual methods.

In this way the copper present as oxide in a normal slag of 0.22% was found to be about 55% of the total copper, while in one carrying 0.455%, due to excessive furnace oxidation, it was 66%. (It is worthy of note that there was also more sulphide in this slag.) Mr. Kiddie found that these ratios agreed with the gold-copper ratios of slag and matte, assuming that the sulphide alone carried gold into the slag. He also fused a quantity of the 0.455% slag with some ferrous sulphide in a crucible, and the resulting slag carried only 0.05% Cu. (Even if all the oxide were reduced and settled in this case, there must in addition have been two-thirds of the sulphide settled.) From these results Mr. Kiddie concluded that if the copper present as sulphide in any slag was as high as 66% of the total it would be advisable to employ a second settler, while if the same amount existed as oxide additional settling capacity would be of no avail. In this latter case he said some of the oxidized copper would be recovered if the slag were passed over a bath of low-grade matte in a second settler.



VARIATION OF COPPER IN SLAG WITH CHANGE OF SLAG COMPOSITION—AFTER WANJUKOFF

C. A. Grabill (*Engineering and Mining Journal*, 1910, Vol. 89, p. 776)—Mr. Grabill classified the losses as physical and chemical. The former consisted of those due to poor settling, insufficient difference of specific gravity of the matte and slag, and gas flotation; but he considered that all of these were small under normal conditions. The chemical losses might be due to the formation of copper oxide or to solution of metals and sulphides. The former he believed to be small in matte smelting, owing to the instability of copper oxide in the presence of sulphides, but of more concern in the production of black copper from oxidized ores. The loss as dissolved metal or sulphide he thought the most serious of all, and suggested that there might be a dissociation of the dissolved matte at high temperatures, like that observed for the slag itself, thus resulting in solution of the separate constituents of matte rather than for the latter as a group.

Owing to the difficulty of carrying out laboratory experiments under commercial conditions he did not place

much faith in results thus obtained in the settling of matte from slag. He thought that in a general way any conditions in the furnace tending to the production of metallic copper would probably raise the copper content of the slags.

W. Wanjukoff (*Metallurgie*, 1912, Vol. 9, pp. 1 and 48)—In an elaborate series of experiments Mr. Wanjukoff investigated the losses of copper in artificial slags of different degrees of acidity, with the oxides FeO, CaO, MgO, ZnO and Al_2O_3 replacing one another in varying proportions, as well as in contact with mattes of all ordinary grades. Some of his curves are reproduced in Figs. 3-6, replotted from the author's data.

He investigated also the relation of copper and sulphur in slags, but found little regularity. The amount of sulphur carried by the slags depended largely upon their pyrite. His conclusion was that much of the copper had been present as oxide or silicate, owing to the contained sulphur being insufficient in amount to unite with all the copper as cuprous sulphide. As a regular treatment for molten converter slag—if iron flux were not desired for blast furnaces—he suggested pouring it into an externally fired settler through the roof of which pyrite was dropped in small quantity. This would require little fuel, and would save the copper without the usual re-smelting of slag.

H. O. Hofman ("Metallurgy of Copper," opp. p. 174 and p. 257)—The analyses of blast-furnace slags in Table 1 are given in Doctor Hofman's book, and have been rearranged in the order of increasing copper content. The names of companies have been omitted, as the only comparison desired is that of the conditions under which

composition, certain metals under favorable conditions passing in as sulphides to a much greater extent than the copper.

In his attempt to find a reagent which would dissolve either the oxide or the sulphide from a slag and leave untouched the other combination, most of the promising chemicals were tried, including H_2SO_4 of moderate strength (temperature not given), HCl, NH_4OH and NH_4Cl, $AgNO_3$ and KCN. H_2SO_4 (1:3) attacked the copper sulphide only slightly, as did HCl (1:7), but all the other reagents appeared to be quite unsatisfactory. His conclusion was that the relative quantities of copper sulphide and oxide could not be even approximately determined.

Metals with High-Sulphur Affinities Carry Copper into Slag

He noticed that slags containing metals with a strong affinity for sulphur were more likely to contain considerable copper than those with metals which did not so readily form sulphides. He gave the following as the order of some of the common metals with reference to their affinity for sulphur, in descending scale: Cu, Ni, Co, Fe, Mn, Zn, Ca, Mg, Al.

John W. James (*Engineering and Mining Journal*, 1914, Vol. 97, p. 1114)—Mr. James told of passing into a reverberatory furnace molten converter slag which by settling had been reduced in copper content to 1.25-1.50%. After a treatment with green poles and charcoal the copper was 0.75-0.85%. Half of this residual quantity was reduced in a few minutes by throwing in a little

certain amounts of copper enter the slag. Table 2 gives similar analyses of modern reverberatory slags.

TABLE 2. REVERBERATORY SLAGS ARRANGED IN ORDER OF INCREASING COPPER CONTENTS—AFTER HOFMAN

	Matte			Slag					
No.	Cu	Sp.G.	Sp.G.	Cu	SiO_2	FeO (+MnO)	CaO (+MgO)	Al_2O_3	ZnO
1	35			0.36	36.8	35.1	9.3	10.5	3.0
2	46			0.37	37.8	38.6	4.0–4.5	6.0

5	35–45	5.0–5.6	3.21	0.45	41.9	33.6	7.4	10.6	
6	45–48		3.3–0.40–0.52	44		29–30	6	6–8	
7	37.27	4.60	3.52	0.51	35.5	33.4	1.8	11.15	1.0

A. J. Bone (Private Communication)—Reference has already been made to the practice of the Tennessee Copper Co. Mr. Bone has kindly supplied the information in Table 3, showing the varying losses as changes were made in the smelting practice there. The saving in copper by adding limestone to the matte-concentration charge is seen to be a striking one, and the greater quantity of slag produced would not materially change these proportions.

TABLE 3. COPPER LOSSES IN SLAGS RESULTING FROM CHANGE IN SMELTING PRACTICE—AFTER BONE

Date	Charge	Matte Cu	Slag Cu	Slag SiO_2	Slag FeO
1901–1904	Rough-roasted ore	41.12	0.474	32.9	50.7
1905–1907	Low-grade matte and ore (No limestone)	38.4	0.662	37.4	51.8
1907–1908	Raw pyrite	31.0	0.420	39.8	44.0
1909–1912	Low-grade matte, with limestone	31.9	0.347	37.4	44.7

Comparing the raw-pyrite smelting and recent limestone smelting it appears that the greater quantity of copper in the charge in the latter case did not raise the copper in the slag materially, being more than balanced by other conditions—(limestone ?).

(To be Continued)

Potash Deposits in Chile

By Severo Salcedo*

Potash was discovered in Chile many years ago, but for reasons too many to enumerate these salts have not attracted the attention of Americans, even though two magnificent samples with 16 and 28% of potassium chloride respectively were exhibited in 1901 at the Chilean pavilion in Buffalo.

The potash salts are found in the Province of Tarapaca, Chile, in Pintados and Bella Vista Lakes, which together have an area of about 10,000 acres. The deposits are only about three miles from the railroad that runs from Iquique to Lagunas.

The potash occurs as chloride in a crust at the surface, samples of which vary from 3 to 36% of KCl. The density of the bed is about 1.352. This superficial crust varies, having an average thickness of 20 cm., but this is only a part of the potash contained in these lake beds, as the water underlying the crust contains the same salts (8 kg. of potassium chloride per cubic meter of brine), which by evaporation and capillarity have formed the salt crust; when the salt bed is removed it is again formed—in 8 to 12 years—by the same process. The data on which this article is based are taken from the reports of Chilean engineers, and especially from the report of an investigation by Messrs. Lemetayer, Martens and Vasques, and of Enrique Taulis.

P. Lemetayer, professor of chemistry in the University of Chile, in company with the chemists, P. Martens, chief of the Government Chemical Laboratory at Iquique, and Doctor Vasquez, made an examination of the Pintados and Bella Vista Lakes in 1905, at which time they calculated a KCl content of 2,037,948 tons in a salt bed, ranging from 3 to 12% of potassium chloride. Up to the present no soundings have been made deeper than 3 or 4 ft. Enrique Taulis, director of the Agricultural College in Santiago, who made a study of the Stassfurt deposits in Germany, also reported on the Guaica deposits of Pintados Lake. He reported in 1901 the following analysis of a sample from a representative shipment of Pintados (Guaica) salts:

	%
Moisture (at 110°)	5 000
Insoluble in water	1 324
Chlorine	37 961
Sulphuric anhydrid	15 334
Calcium	0.272
Carbon dioxide	0 134
Sodium	29.533
Potassium	7 409
Magnesium	trace
Oxygen of the sulphates	3 066

This elementary composition corresponds according to the laws of chemistry to the following:

	%
Calcium sulph	0.925
Sodium carbonat	0.323
Sodium sulphat	28.392
Sodium chloride	51 447
Potassium chloride	14.151

Having crystallized a solution of these salts, he concluded from a study of their crystallographic character that none of the potash was present as sulphate. Hence, all of the potassium is calculated as chloride. It is important to note the absence of magnesium salts, as well as that of bromides or iodides, which have a toxic action on plants. Mr. Taulis determined that the calcium salts existed in the form of sulphates, and that the deposit might be considered as consisting of sulphate of sodium and chlorides of sodium and potassium, which fact simplifies the economical extraction of concentrated salts. In normal times the Pintados salts would have to compete with the Stassfurt products, and he made the accompanying comparison of the Pintados salts with that of carnallite and kieserite, the Stassfurt salts which most nearly approximate the Guaica deposit. Magnesium chloride, having a high solubility, increases the cost of purification on account of the complicated procedure required for such salts.

COMPARISON OF STASSFURT AND PINTADOS SALTS

Composition	Carnallite	Kieserite	Pintados
Potassium chloride	15.5	11 8	14.15
Magnesum sulphate	12.1	21.5	none
Magnesium chloride	21.5	17.2	none
Sodium chloride	22.4	26 7	51.45
Calcium sulphate	1.9	0.8	0.93
Sodium sulphate	none	none	28.29
Insoluble in water	0.5	1.3	1.32
Moisture	26.1	20 7	5.00

Taking the composition of the Pintados salts as sulphate of soda and chlorides of soda and potassium, and keeping in mind that the maximum solubility of sulphate of soda is reached[1] at a temperature of 20° C., at which the chloride dissolves only to a small extent, it will therefore suffice to submit these salts, suitably ground, to a lixiviation with water at this temperature to dissolve the whole of the sulphate and only a part of the chlorides. The residue of this first washing will consist of a mixture of chlorides. The solubility of the chloride of potash increases with rise of temperature, while that of chloride of soda remains constant.

On the other hand, since the solubility of sulphate of soda decreases with increase of temperature, if the water from the first lixiviation be heated the sulphate will be partly eliminated and all of the chlorides retained in solution. Since the potassium chloride is more soluble than the sodium chloride, the crude salt can with a single lixiviation be exhausted completely of its potassium chloride, obtaining a product with a concentration of more than 40% of chloride of potassium. By means of lixiviations successive to those already indicated, the concentrated salts can be produced with a content of 90% potassium chloride, if necessary.

One-third of all the chloride of potassium sold in Europe is used for the manufacture of potassium nitrate from the nitrate of soda imported from Chile. These two salts being only a few miles distant in the Province of Tarapaca, the benefits that can be derived are obvious. To make 100 kg. of potassium nitrate it is necessary to use 73.95 kg. of chloride of potassium and 84.15 kg. of nitrate of soda (Chile saltpeter). Hence it would be easy to undertake this manufacture in Chile. A freight of 58 kg. on inert substances would be eliminated for each 100 kg. of nitrate of potash exported.

It is worth noting that the pipe line supplying potable water to Iquique passes across the Pintados properties. This pipe line, or the wells situated in the vicinity, can supply sufficient water for an extraction plant.

It is to be hoped that in the near future the world will not have to depend exclusively on the European monopoly which has for so many years dominated the potash market. An engineer left New York on July 24 to examine the Pintados deposit for American interests, which will immediately undertake the exploitation of the Chilean potash if the representations of the local engineers can be substantiated.

*149 West 35th St., New York.

[1] Given by other authorities as 32.3° C.

Orebodies of the Mesabi Range--IV

By J. F. Wolff*

SYNOPSIS—Previous theories as to ore formation correct in main features. Three types of bodies related. Relation between folds and orebodies. Fracturing permitted entrance of groundwater, leading to iron concentration. Function of the Intermediate slate was to control water circulation. Western Mesabi sandy ores due to lack of vigorous circulation and of transportation of silica. Discussion of probability of correctness of conclusions.

In the preceding parts of this series the structure and exploration of Mesabi range orebodies were discussed for the particular assistance of engineers in the district. This part will present additional data from which, together with what has gone before, conclusions will be drawn as to the geological conditions under which these orebodies have developed. Of course it is impossible to prove absolutely that any one set of causes governed the formation of the ore but I believe that sufficient positive information is at hand from which to draw valid conclusions.

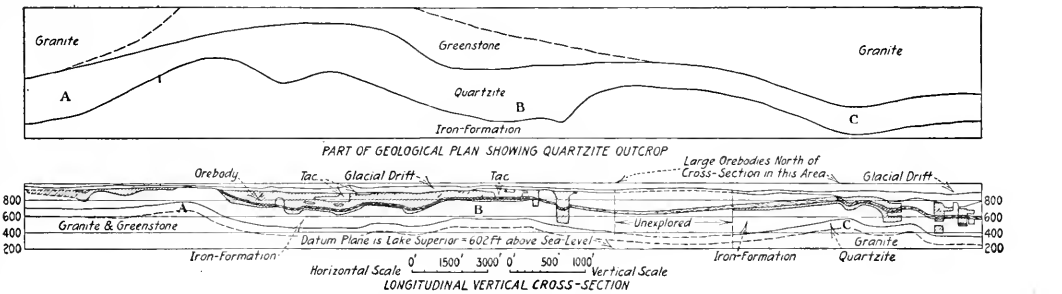

FIG. 28. LONG PLAN AND SECTION SHOWING RELATION OF ORE TO STRUCTURE

In the first article, the process of actual formation of the ore by the leaching out of the silica, the oxidation of the iron and the compacting or slumping of the iron in place was described. All mining engineers and geologists who have had anything to do with the Mesabi range in recent years are agreed upon this process of formation. It was simple, and ordinary close observation is all that is necessary to establish it; but the geologic conditions which allowed this leaching and oxidation in certain places and not in others are not directly observable and have been worked out only after the study of the great mass of information available to me which was mentioned near the end of the first article.

Previous Theories

In 1894 in Minnesota Geological Survey Bull. 10, "The Mesabi Range Iron-Bearing Rocks," J. E. Spurr presented the theory that the orebodies were formed in zones of weakness produced by faulting or fracturing of the rocks. He inferred that the fracturing occurred for the most part along the axes of anticlines. In U. S. Geological Survey Monograph 52 Van Hise and Leith present the theory that the orebodies have occurred in gently folded synclines and anticlines, which were produced by the slight warping or folding of the iron-bearing rocks. In neither of these publications was there presented any direct evidence in support of these theories other than a discussion and statement of general field observations. It is proposed here to present geological plats and structural sections to show that in the main both of these theories are correct. Spurr's observations were made upon the orebodies from Mountain Iron east, because at this time little work had been done west of Mountain Iron, and his theory has application mainly to the orebodies now included in the Virginia, Eveleth, McKinley and Biwabik districts. Van Hise and Leith had practically the whole Mesabi range as a field for their investigations and their theory is applicable broadly to the entire range. It is a matter of considerable satisfaction to find that theories based upon broad field observations are so closely in accord with facts worked out from detailed explorations. Spurr probably emphasizes faulting more than the facts as now known will warrant, but his principal idea, that the orebodies from Mountain Iron east have formed in zones of fracturing and consequent weakening of the iron formation layers, seems to be substantiated. From a practical standpoint the theories of Spurr and Van Hise and Leith are essentially the same.

Three Types of Orebodies

The Mesabi orebodies, as previously noted, may be divided into three types, viz., trough bodies, flat-layered bodies and fissure bodies, named in the order of their importance. The structure of the trough bodies has been described and emphasized in the preceding articles as being the typical structure, because by far the larger part are of this type. The flat-layered bodies are generally continuations of the trough bodies and some of them are extensive laterally but of moderate thickness, about 50 ft. being a maximum. The fissure bodies generally occur along the limits of larger trough bodies. They are simply narrow vertical fissures of ore which are the alteration of the taconite on vertical cracks in it. They really represent a step in the formation of trough bodies, being incompletely formed orebodies. There are a few bodies of this type

*Mining engineer, Oliver Iron Mining Co., Duluth, Minn.

, but these apparently are the remnants left by the erosies but these apparently are the remnants left by the erosion of former large bodies. This type of orebody will be understood better by reference to Fig. 36. The second stage *B* in the formation of a trough body is a good cross-section of a fissure body. It remains to explain what probable geological conditions controlled the formation of these three types.

Structural Sections

In order to determine whether or not any relation exists between the positions of the orebodies and the general structure of the iron formation, a longitudinal section 30 miles long, parallel to the strike of the iron formation and taken approximately midway between the limits of the iron-formation outcrop, was made for that part of the range between Sections 17, 58-19 and 24, 56-24. This sec-

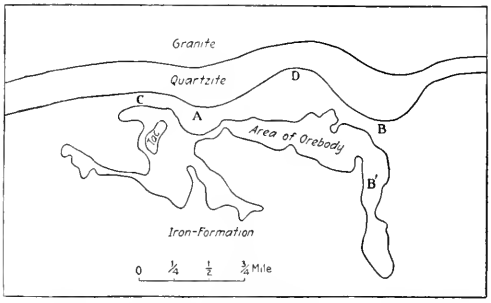

FIG. 29. OREBODY CORRESPONDING TO STRUCTURE SHOWN BY QUARTZITE OUTCROP

tion reveals some interesting facts. A part of it is shown in Fig. 28. It was prepared from all of the drill information available. Examination of Fig. 28 shows that the orebodies conform closely to the major structure of the iron formation and the quartzite, i.e., they occupy the troughs of the synclines and the crests of the anticlines (it should be noted that the vertical scale is 3⅓ times the horizontal). The section shows two main troughs in the quartzite between the anticlines marked *A*, *B* and *C*. Between the points *A* and *C* are the most extensive orebodies of the range and the great size and lateral extent of these are directly connected with the major folding of the iron formation as shown on the section. The plan in Fig. 28 shows the quartzite outcrop and its relation to the underlying granite and greenstone, and to the overlying iron formation. Attention is called to the relation between this outcrop and the quartzite shown in the section. Casual observation shows that the embayments in the quarzite line on the plan correspond to the troughs or synclines in the quartzite on the section. Letters *A*, *B* and *C* on the plan correspond to letters *A*, *B* and *C* on the section and indicate the axes of gentle anticlinal folds. The distance between *A* and *B* appears greater on the plan than on the section, because the section is taken about a mile south of the quartzite outcrop and the axes of the anticlines *A* and *B* converge toward the south. This general relation between the shape of the quartzite outcrop and the structure of the formation is an important one to recognize and it will be referred to later. Of course, minor irregularities in the quartzite line may be due to irregularities of erosion. It may be thought also that the irregularity of the quartzite outcrop simply represents the contour of the shore line upon which the quartzite was laid down, but this is hardly probable because the original shore line must have been several miles north of the present outcrop and progressive erosion has steadily moved the outcrop southward. There is so direct a relation between the outcrop and the section shown as to make the conclusion irresistible that the large bends in the outcrop correspond to the structural folds in the formation. Indeed it seems impossible that there should not be such flexures in a sedimentary series as extensive as the Mesabi. Structural study of the part of the range represented in Fig. 28 reveals many minor folds in the major folds and field observations show minute warping and bending of the taconite and ore layers. Thus there are gentle folds of all orders from extremely large ones down to those of small dimensions in the iron formation. Similar study and observation confirm this fact for all parts of the range.

A further interesting fact revealed by this 30-mile section is that on the western end of the range, where the sandy ores exist, no marked folding of the series has occurred. The deformation has been so slight that the quartzite line is practically flat.

Areas of Orebodies

Figs. 29 to 35 inclusive show the areas of different orebodies and their relation to the general surface geology. By applying the fact above established regarding relations between quartzite outcrop and structure of the formation, the relation between the locations of orebodies and the general structure of the formation can be inferred. For example, Fig. 29 shows an orebody which corresponds roughly to the general structure shown by the quartzite outcrop. It occupies the axes of two antielines *A* and *B* and the troughs of two gentle synclines *C* and *D*. The part of the orebody *B'* is evi-

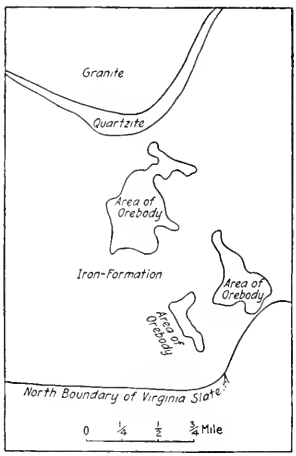

FIG. 30. OREBODIES ON AXIS OF ANTICLINE

dently on the axis of the anticline *B*. Fig. 30 shows orebodies which have been formed on the axis of a pronounced anticline. On this plat both the quartzite and the Virginia slate lines indicate the location of the anticlinal axis. Figs. 31 and 32 show other orebodies which are formed on the axes of antielines. Fig. 33 shows an orebody which has no apparent relation to any structural feature of the formation. It has pronounced sharp walls and is comparatively deep. From the general shape and direction of the orebody one would infer that it had formed on the locus of fissures or cracks cutting across the strike of the formation at angles

of 20° to 80°. Fig. 34 shows an orebody, part of which, *A*, occupies a structural basin in the formation while the other part, *B*, apparently occupies the axis of an anticline. A careful structural study of the drilling in this area proved that these inferences are facts, because there is a marked flexure down to the east, in the layers of the iron formation just east of orebody *B*. Fig. 35 shows an extremely large orebody and one which is somewhat exceptional. Apparently it occupies a general synclinal fold. The three lobes *A*, *B* and *C* unite to form the major trough *D*. From their relations to the quartzite outcrop the branches *A* and *B* seem to be on either side of the axis of a small anticline and the branch *C* appears to be directly on the axis of another small anticline. This body is the best example on the range of two or more troughs uniting to form a larger one. It is a large body, as can be seen by reference to the scale on the plat, while the ore is deep and has sharp rock walls. Parts of this body were explored in the early days and from the information gathered in this and in orebodies represented in Figs. 30 and 34 Spurr drew his conclusions regarding the geological conditions which allowed the formation of Mesabi ore. The orebodies represented in these figures are from the most important producing parts of the range. They are the smaller of the principal bodies. Those shown in section in Fig. 28 and those on the western part of the range are so extensive in area that they are not included here nor would their representation be of more value to the present purpose. From what has been presented some definite conclusion can be drawn as to the geological conditions governing the formation of the ore.

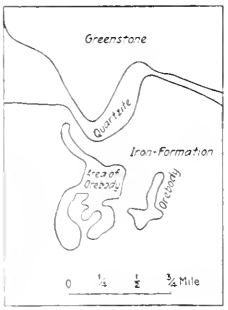

Fig. 32

OREBODIES ON AXES OF ANTICLINES

Geologic Conditions under Which Orebodies Formed

The evidence already presented in this and preceding parts shows conclusively that the sedimentary rocks of the Mesabi range have been gently folded and fractured and in a few places faulted by the earth movements which have occurred since their deposition. Because of its brittle nature, the iron formation yielded to this folding by fracturing and by slight bending of the layers. A great deal of gentle major and minor folding has been disclosed by close structural study of exploration and mining work. Almost everywhere the taconite is found to be broken into parallelopiped rocks by at least two sets of fractures, the directions of which are not the same in all areas. In some places, particularly on the axes of anticlines and synclines, this fracturing has been pronounced and in these localities groundwaters found their way into the formation most readily. In other places, such as the large areas represented in Fig. 28, the fracturing must have been general rather than localized. In such an area the penetration of groundwaters must have been extensive, and therefore orebodies extending over large areas have been formed. The gentle rolls in the formation made natural structural channels, controlling the flow of underground waters. The smaller bodies formed where the cracking was localized. The process of leaching out the silica and the concentration and slumping of the ore need not be described again here, since it was discussed in part I. However, Fig. 36 is presented to show the probable development of one of the smaller bodies on a series of parallel fissures. The successive stages shown illustrate the progressive development of the orebody better than would a long description: this is not the mere expression of a theory but is well founded on fact. All four stages shown, and even intermediate stages, can be observed in the orebodies themselves. In Fig. 36, *A* represents tension cracks in the iron formation on the axis of a gentle anticline: *B* represents the formation of ore by the alteration of the taconite on the vertical fissures and along bedding planes: *C* represents the process of alteration well advanced: and *D* represents the present condition of the average orebody. Surface erosion of taconite and ore is shown also. This illustration refers particularly to the deep, sharp-walled trough bodies from Mountain Iron east. The same process has operated, but over large areas, in the Hibbing, Chisholm and Western Mesabi districts. The rock horses and rock pillars found in the lower blue ore in every deep-trough orebody are simply incompletely altered blocks of taconite. In many bodies, in which mining has progressed far enough, stringers of ore can be followed out into narrow fissures in the rock until they finally give way to decomposed taconite which in turn gives way to solid taconite. On the edges of a few orebodies these stringers or vertical fissures of ore are so numerous that they constitute what have been referred to previously as a fissure type of orebody. The orebodies formed by the complete alteration of the fractured areas or zones as above described are characteristic trough bodies (*D*, Fig. 36). The origin of the third type of layered body will be discussed now.

From the persistence of the altered Intermediate slate layer or the paint-rock layer (Parts I, II and III) it

must be evident to the reader that this layer has had a marked influence in the formation of the ore, otherwise the paint-rock layer would not be found so universally in the ore. One would expect to find alteration of the taconite immediately above the quartzite or of the taconite immediately below the Virginia slate as frequently as one finds alteration of the part of the formation both above and below the Intermediate slate layer. It remains therefore to secure an explanation of the presence of the Intermediate paint-rock layer in almost every orebody of any size and importance. When erosion started to truncate the Mesabi series, surface waters flowing over the top of the iron formation seeped into it in fissured areas. The waters flowing down the greenstone and granite flowed first on the iron formation below the Intermediate slate layer and entered this formation wherever possible. The waters which flowed across the outcrop of the Intermediate slate layer entered the fractured upper taconite wherever it was sufficiently broken up. The Intermediate

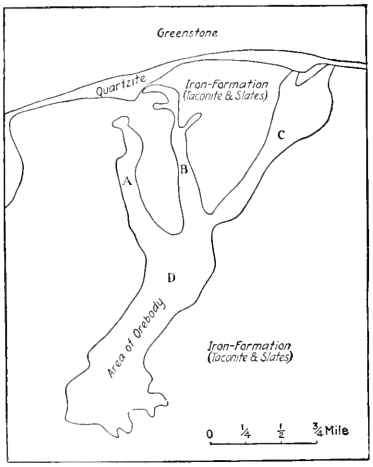

FIG. 35. LARGE OREBODY FORMED OF SEVERAL JOINED TROUGHS

slate itself is relatively impervious to water except for the cracks which traverse both it and the taconite above and below it, and which allow water to penetrate into it and through it. It is not so permeable as the taconite in any sense. Therefore the waters in the taconite underneath it were considerably ponded. The waters in the taconite above the Intermediate slate flowed down under the Virginia slate until they became ponded under it The Intermediate slate thus acted as an impervious basement for the upper waters and ponded the lower waters; together with the folds in the formation it controlled the circulation of the groundwaters. Fig. 37 is a diagram illustrating the probable circulation of water within the iron formation. Above the Intermediate slate layer an artesian circulation must have been set up by the ponding of water under the Virginia slate. Evidence of this is to be found in the flowing wells which have been developed in several places by drilling through the Virginia slate into the iron formation beneath it. Further evidence is found in the existence immediately beneath the Virginia slate of a layer of almost pure chert or extremely cherty taconite, 5 to 20 ft. thick. This layer is badly broken up and is always difficult to drill through. Its exceptional chertiness may be the result of deposition of silica out of the waters ponded under the slate (Fig. 37). The diagram shows the circulation of the waters beneath the Intermediate slate as finding its way through cracks in the slate up into the upper taconite. Immediately below the slate layer there may have been a return current making its way to the outcrop. Evidence of this is to be found in the incomplete alteration of the lower yellow taconite in most of the orebodies in the eastern part of the district and in the excessively sandy layer found in

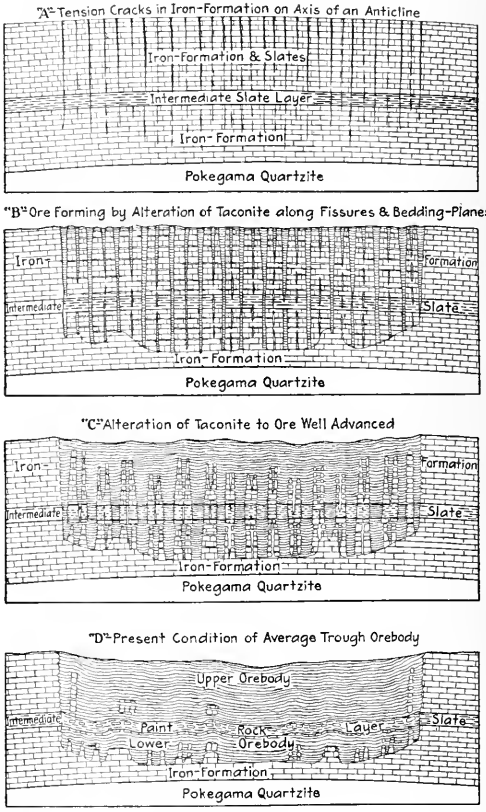

FIG. 36. DEVELOPMENT OF OREBODY THROUGH FISSURE TYPE TO TROUGH TYPE

the bodies from the Hibbing district west. This evidence means either that there was incomplete circulation and consequent solution and transportation of silica from the formation immediately below the Intermediate slate layer or else that this sandy ore and rocky layer under the slate represents precipitation of silica out of solution, due either to the ponding of water or to a reaction with the alumina in the slate layer. There is good evidence that the escape of the waters beneath the Intermediate slate was through cracks or fissures extending from the upper taconite down through the slate. In several flat-layered orebodies beneath the slate, where no extensive

body occurs above this layer, individual drill holes or a few drill holes show that fissures or chimneys of ore extend from the surface down to the slate layer. Since the ore in these drill holes is not connected with any large orebody the inference seems reasonable that the ore in them was caused by waters ascending from beneath the slate layer rather than from descending surface waters. There is no other explanation for the outlet of these waters ponded underneath the Intermediate slate and the evidence of these chimneys or fissures of ore in the upper taconite suggests directly the explanation just given.

Flat-Layered Bodies

In Fig. 12, Part II, there is shown a section of a flat-layered body which is the continuation down the bedding of the iron formation from a trough body. This flat-layered body is derived from the lower yellow taconite. The occurrence of extensive flat-layered bodies as extensions of trough bodies immediately underneath the Intermediate slate is so common all over the range as to attract immediate attention. The explanation seems simple enough. The waters ponded underneath the slate layer sought escape laterally along bedding planes and their flow was directed by the gentle folds in the formation until they found outlet through fissures extending from the

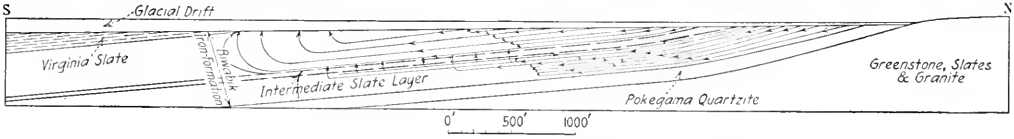

FIG. 37. DIAGRAM OF PROBABLE WATER-CIRCULATION

upper taconite down through the Intermediate slate. As previously indicated, these orebodies are not thick or of exceptional richness. Down the slope of the bedding some of them grade into lean ore or decomposed taconite. Parts of them are not of merchantable grade.

There are other flat-layered bodies in the upper taconite. For the most part these are extensions down the dip of trough bodies. Some of them may be the remains of larger bodies which have been removed chiefly by preglacial erosion.

Alteration of Intermediate Slate

Although the Intermediate slate layer has been spoken of as an impervious layer this term, of course, is a relative one. The tremendous length of time during which alteration has proceeded has caused even this layer to be partially or completely altered by the solvent and oxidizing effect of groundwaters. In many places the upper and lower parts of this layer are well altered and a slate core remains. This is further direct evidence of circulation both above and below the layer. In other orebodies or parts of orebodies this layer is completely altered and is now a soft clayey material infiltrated with iron precipitated out of solution. Its moisture content is much higher than that of the altered taconite.

This member is so dense and homogeneous that the only alteration which has occurred in it has been at its contact with the iron formation. In some places the upper 5 or 10 ft. of it has been decomposed into a sand and in one place it is known to be so saturated with iron from the orebody above as to be practically an ore. Aside from this alteration the quartzite apparently has been impervious to groundwaters.

The Sandy Western Mesabi Ores

The best explanation known to me, of the occurrence of large amounts of low-grade ores and sandy washable ores on the Western Mesabi is the one suggested by the longitudinal section referred to above, part of which is shown in Fig. 28. As already stated, this section reveals no structural basins in the quartzite in the Western Mesabi district. Therefore no natural underground water channels have controlled the circulation. The waters simply seeped into the iron formation, having no definite drainage courses as in the central and eastern part of the district. Moreover the dip of the formation is extremely gentle, being only about 4% or 5%. Therefore, while decomposition of taconite and oxidation and concentration of iron have been quite complete in this area, the solution and transportation of silica out of the orebodies have not been complete.

Summary

In order to emphasize the essential facts set forth in these articles a general summary seems not out of place. In Parts I and II the general structure of the Mesabi range and its orebodies was pointed out and exceptional structural features were described and illustrated. It was shown that all orebodies on the range from one end to the other have a uniform structure. They occupy irregular trough-shaped basins in the taconite or country rock. They consist of an upper and a lower high-grade member separated by a low-grade member which is the alteration of an interbedded slate layer. Ordinary close observation of exploration and mining work will disclose to the engineer or mining man this characteristic structure of a typical orebody.

In Part III the method of exploring Mesabi range orebodies was described and illustrated. The best known method for determining the structure from the exploration records was presented in detail and illustrated with a complete set of structural vertical sections of an orebody as I actually worked it out for commercial purposes.

In Part IV additional data have been given from which, together with those presented in the first two articles, well defined conclusions have been drawn as to the geological conditions under which the Mesabi range orebodies have developed. I have shown that exploration and mining work and particularly close structural study of all parts of the range substantiate the theories which J. E. Spurr in 1894 and the geologists of the U. S. Geological Survey since 1903 proposed regarding the geological conditions determining the formation of the orebodies, viz., that they formed in zones or areas where the iron formation was much cracked or broken up, due principally to gentle warping or folding and slight faulting of the Mesabi series of ore formations.

I have presented these articles in order to diffuse among engineering and mining men particularly on the Mesabi range a knowledge of a great many facts valuable to them in their work. All of this information represents results of several years' observation and study, but it is not presented as being the last word on the subject by any means. Rather it is presented as an outline on which others may work.

It is hoped that the present articles will instigate and stimulate work in this direction, so that there will be uniformity of effort along these lines and eventually the structure and geologic history of the Mesabi range will be known more completely than that of perhaps any other mining district in the country.

Forfeiture of Placer Locations

By A. L. H. Street*

In affirming a decree quieting title to a placer-mining claim as against a junior location, the Supreme Court of Oregon decided the following principal points related to forfeiture of such claims:

Clearing brush and trees from the surface of ground located constitutes such assessment work as prevents forfeiture of a claim, when it is done for the purpose of enabling the claim to be worked by dredging.

When a junior locator asserts forfeiture of the claim by the senior locator through failure to do annual assessment work, the burden is on the former to establish such failure, rather than on the latter affirmatively to show performance of the work.

Resumption of work by a senior locator before relocation by another defeats a relocation.

Since it is only against intervening rights that a resumption of work by a locator does not revive the possessory rights of the claimant, it must be held that where the senior locator of a placer claim failed to do required assessment work, a relocation of the claim by another person, who also failed to perform assessment work for a succeeding year, does not forfeit the right of the senior locator to resume work thereon, so as to authorize a third person to relocate the claim after the senior locator had done the assessment work for a succeeding year. (Richen vs. Davis, 148 Pacific Reporter, 1130.)

Electric Steel Production

There were, at the beginning of 1914, according to the *Elektrotechnische Zeitschrift*, 138 arc furnaces and 35 induction furnaces in operation for the production of steel. The arc system is thus far more generally in use, though judged on the basis of steel output the advantage would appear to be with the induction system. The opinion expressed in recent years that the induction furnace would prove the better of the two, has given place to the conviction that each system has its own special field of operation. So far as the sizes of the furnaces are concerned the problem of a construction for a capacity over 15 tons has yet to be solved. Larger furnaces than the 25-ton Heroult have not yet been constructed, and the practicability of this dimension has not been demonstrated as yet. The Girod system has attained the 15-ton margin, the Nathusius and Röchling-Rodenhauser 12 tons, while the production of castings on the Stassano method is limited to small units of no more than two tons. Nevertheless, units of 30 tons are still being built on the Heroult system and 20 tons on that of Frick. During 1913 the output of the electro-thermic steel works increased in Germany, Austria-Hungary and France, though the increase was less than in previous years. The total production in North America remains nearly stationary. On the whole, it is the general belief now—as against previous opinions to the contrary—that the electro-steel industry has a long period of development still confronting it, and that the experimental stage is far from having been passed.

Herewith is given a list of the several systems and their development in 1913 and 1914. Arc furnaces working and under construction: Heroult 67, Girod 27, Nathusius 9, Stassano 10, Keller 6, Chaplet 8, others 11; total 138. Induction furnaces working and under construction: Kjellin 10, Röchling-Rodenhauser 17, Frick 6, others 2; total 35. There are therefore 173 electric furnaces altogether.

Extracting Potash from Salines of Low Potash Content

While the admixture of previously cooled solutions of nitrate of soda and of chloride of potassium results in the formation of a precipitate of nitrate of potassium, the sodium chloride remaining in solution, if the product to be treated contains slight amounts of chloride of potassium mixed with, for example, large quantities of salt, the reaction may be invisible. It is not possible to secure the precipitation of the potassium nitrate, because its solubility is increased by the presence of the salt. M. M.-E. Pichard proposes to turn this to account in the extraction of potash from saline deposits poor in potash, the method of working on the industrial scale being given thus by the *Chemical Trade Journal*:

In a saturated and cooled solution of NaCl is dissolved the small quantity of nitrate of soda necessary for the conversion of the KCl contained in the crude salt to be treated, over which this solution is passed, keeping the whole at a low temperature. KNO_3 is formed and is carried away by the solution of NaCl. The foreign elements of the crude salt, NaCl, Na_2SO_4, $CaSO_4$, remain insoluble. The potassium solution containing KNO_3 in presence of NaCl is evaporated down, and deposits a mixture of these two salts. Separating them is most easily effected by warm water, which dissolves the potassium nitrate and leaves undissolved the sodium chloride which has acted as a vehicle, and is used again. The residuary salts are dissolved, and the cold produced by their solution is utilized in the application of the process.

The Philippine Bureau of Science Reports that examinations have been made of the discoveries of iron ore recently reported from Surigao Province. Samples were taken by drilling over an area of 100 sq.km. The deposit was found to be singularly like the Mayari iron ores near Nipe Bay, Cuba, in its occurrence; that is, it is a great surface blanket of iron-bearing clay, which has resulted from the weathering and decomposition of the original rock. In the case of the Surigao deposit the parent rock is made up principally of the mineral serpentine. The ore deposit is of varying thickness, in many places entirely carried off by erosion. Further investigations are being made; also analyses of the iron ore samples.

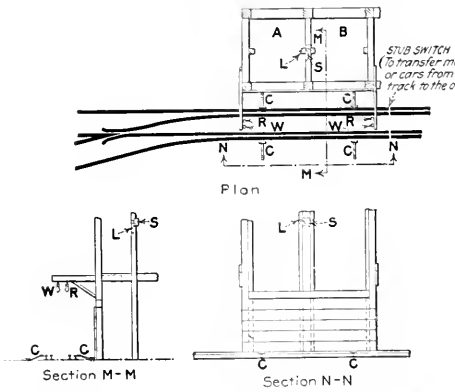
Details of Practical Mining

Automatic Signal System Used in Stockpiling Iron Ore

By John F. Murphy*

During the winter operations of underground iron mines in the Lake Superior district, it is necessary to stockpile ore until shipping begins in the spring. With usual practice, shafts have two hoisting compartments where the skips are hoisted in balance. The ore is dumped directly from the skip into a car on the stockpile trestle. Consequently, the hoisting engineer must know that the skip is loaded and also that a car is in the proper place on the trestle.

At one of the large underground mines on the Mesabi Range in Minnesota the following signal system was used for this purpose: A bell operated by the underground skip-tender indicated to the hoisting engineer that the skip was ready to be hoisted. A red electric light, operated by a man on the trestle, showed in the engine house that a car was correctly spotted under the skip road. This system was used only during the first winter of operation—an unusually cold winter. Work was plentiful, so that all the experienced men found employment underground. Only an inferior class of labor could be procured to work on the trestle. It was unusual for work to be carried on continuously for two weeks without hiring a complete new trestle crew. Thus, because of the inexperience and negligence of the trestle gang, several times each day the spotter would spot the car under the wrong skip road, signal the engineer, and the skip would be hoisted and its load dumped on the rails, usually between two cars or between a car and the motor. This spilled material was difficult to remove on account of the limited space between the cars. Often so much time was lost that all available underground storage room would become filled and mining operations delayed until hoisting was resumed.



DETAILS OF AUTOMATIC SIGNAL SYSTEM

The following automatic-signal system was devised and installed to eliminate the man employed as car-spotter and signalman on the trestle, and also the trouble resulting from cars being spotted incorrectly. A red light on the trestle in front of each skip road indicated to the motorman the next skip to be hoisted. These lights were operated automatically by the skip. A white light at the side of each red light indicated that a car was spotted correctly under the skip road. Each of these white lights was operated by a spring which closed a circuit with the car wheel. A red light and a white light burning side by side showed the motorman that the car was in the proper place to receive ore from the next skip to be hoisted. Two red lights in the engine house on either side of the indicator disk showed the hoisting engineer that the car was in place and which skip it was under. The red lights in the engine-house were on the same circuit as the white lights at the trestle.

The accompanying diagram, with description, illustrates more clearly the manner in which the system operates: An electric switch S controlled by the lever L is located between the two adjacent skip guides. When the skip A is at the bottom of the shaft a red light R burns in front of the A-skip road. When the A skip strikes the triangular lever L the switch S is pushed over on the other line, extinguishing the red light in front of the A-skip road and lighting the one in front of the B-skip road, thus showing that the skip B is at the bottom of the shaft.

The white lights W are controlled by the springs C, which complete a circuit through the car wheel to the rail. Springs C are so located that when a wheel is in contact the car is correctly spotted to receive the ore from the skip. The red lights for A and B skips in the engine-house are operated by the connection C.

The advantageous results of this system were at once apparent. Work on the trestle ran smoothly and steadily. Cars were spotted quickly and in the proper place. Signals from the trestles were received by the engineer the moment the cars were spotted. A man was required at the shaft only an hour or so a day to remove the small amount of ore spilled over the tops of cars while loading. Loss of time by contract miners was thus eliminated.

Rubber Belting Briefs

A Goodyear trade publication gives the following suggestions regarding the care and use of rubber belts:

Belts should not run less than 200 ft. per min.

Average velocity of belts should be 2000 ft. per min.

Maximum velocity of belt should be between 5000 and 6000 ft. per min.

When running at high speed the centrifugal force of the belt has a tendency to remove it from contact with the pulley, thereby lessening the horsepower transmitted.

All animal oils and grease are injurious to rubber belting.

Shifters should not be used on rubber belting. Once the edges are worn through the plies readily separate.

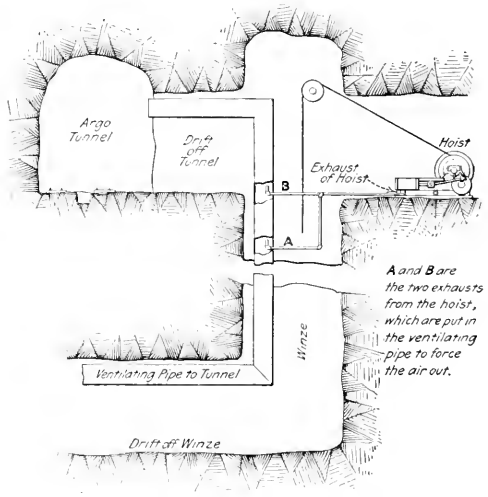
Large face pulleys and normal speeds, proper tension and plies of fabric give best service.

Vertical belts require extra tension to obtain sufficient friction on the lower pulley.

Ventilating a Dead Heading

By P. Ruth, Jr.,*

Having bad air and rock gas at the end of a drift from the bottom of a winze, a 10-in. ventilating pipe was installed from the breast of the drift to and up the winze and connected with the main tunnel above. The natural circulation of air through this ventilating pipe, contrary to expectations, would not move the gas and bad air,



VENTILATING A DEAD HEADING

which were as troublesome as before. At the top of the winze was a small hoist operated by compressed air. By running the exhaust from this air hoist into the center of the ventilating pipe a draft was created which did the work as well as a blower and gave satisfactory results in the way of ventilating the drift below. The hoist is working almost all of the time, so that the benefit is continuous. The exhaust from an air-driven mine pump could also be used for the purpose.

Rate of Hand Tramming

At the Colby iron mine, Bessemer, Mich., when tramming was done on straight company account the trammers were handling on an average 12½ tons per man per shift. This system was changed to a straight contract system, with a fixed price per ton, which was not changed throughout the year. Under this system an average of 21.4 tons per man per shift were handled regularly. Two trammers constituted a gang. The size of the car was 1-ton capacity, and the average length of tram was 100 ft., it varying from 25 ft. to 275 ft. The length of tram made little difference apparently, as the superintendent of the mine states that for short trams the speed was 80 ft. per min. and for the long trams 330 ft. per min. The ore was loose and freshly broken and the ventilation was fair.

During 10 months 30,318 tons of ore was trammed in 1419 8-hr. shifts. The lowest number of tons trammed per man per shift was 18.6, the highest 23.2 and the average 21.4 tons.

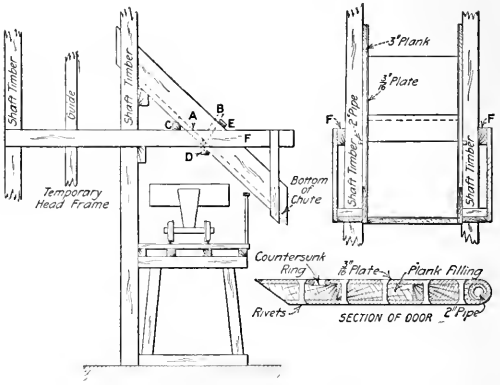
*Idaho Springs, Colo.

Rock- and Ore-Chute Door

By D. E. Charlton*

The accompanying sketch shows a combination rock- and ore-chute door that was made use of at one of the Mesabi Range mines. The shaft had been sunk the required depth and guides were placed in the hoisting compartments. Two drifts were started in rock, and one shortly afterward encountered ore of a merchantable quality. The ore demanded as early a shipment as possible. Because of this and the nonarrival of the headframe that had been ordered, the arrangement described was devised to be used with the temporary or sinking headframe, so that the ore might be hoisted and placed in the cars for shipment without interfering with the hoisting of the rock.

A Kimberley dump skip was substituted for the regular sinking bucket, and dump plates were placed on the temporary headframe. The position of the door when ore was being dumped is shown at *A*, the ore passing down the chute to the ore cars. When rock was hoisted



DETAILS OF DOOR AND CHUTE

the door was swung back to the position *B*, so that the rock passed about half-way down the chute and thence into the dump car and was trammed to the rock pile. The lower side of the door in this case acted as a buffer. A small trestle was built to bring the dump car to the required height, so that the rock in falling would do no damage to the car.

The bottom and sides of the chute were of 3-in. plank, lined with $\frac{3}{16}$-in. iron plate. In the construction of the

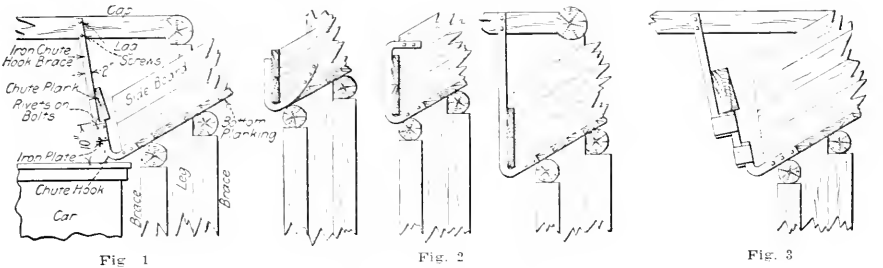
*Virginia, Minn.

door, as shown in the sketch, the plate was formed into an extended U-shape and filled with plank, the lower end of the U and a 2-in. pipe forming the hinge on which the door could swing. The plate was firmly fastened to the plank by means of countersunk rivets. At the upper end, a countersunk ring placed on the upper side of the door served as a means of lifting it. The door extended the entire width of the chute, and when open gave an aperture of 2 ft. 3 in. Crosspiece *D* served as a bearing piece for the chute and for the hinge of the door, the pipe extending through the main support, which was tied to the main shaft uprights. Crosspiece *C* served as a support for the door at the upper edge, which was beveled to meet the bottom of the chute at this point. The door, when thrown into position for dumping rock, had a backstop *E*.

An Improved Chute Hook

A serviceable and durable chute hook may be easily made as indicated in the accompanying drawing, Fig. 1. The chute hook is made of 2x1½-in. or 2x⅝-in. iron, as shown. Connected to this, by a pair of iron plates, riveted or bolted, is another 2x1½-in. iron strip which is fastened to the cap above by lagscrews. This brace strengthens the hook and allows a backing for the chute plank entirely to cover the chute mouth. The object in this break in the hook is to allow a resting place for the chute plank. There should at all times be a plank in the chute to prevent runs of rock. If no place for the plank is provided the trammer will take it out, set it beside the car and use the bar, causing frequent runs of rock, which necessitate shoveling up the track. To most miners the value of this rest is self-evident; but too many chutes have hooks as indicated in Fig. 2, which necessitate removing the plank entirely or require one chute man on each side to hold the plank up while running out the rock.

A second rest may be provided like the first by inserting a 10-in. piece of brace iron and a second pair of plates. A rest for two planks may be made as indicated in Fig. 3.



TYPES OF CHUTE HOOKS

Too Short Steel Piling

In a test pit at an iron mine near Riverton, Minn., sheet-steel piling arranged in circular form was used, and it was found that too short lengths of piling made it very unsatisfactory and difficult to handle. Although the Riverton country is sandy, the piling in this pit was not satisfactory after the water level was reached on account of considerable buckling of the piling sheets.

Relocation of Mining Claims

By A. L. H. Street*

The Arizona Supreme Court dealt with questions concerning the sufficiency of notices of relocation of mining claims in the recent case of Stratton vs. Copper Queen Consolidated Mining Co. (149 Pacific Reporter, 389). Referring to the Federal statute which authorizes a relocation where an original locator has failed to perform the required annual work, and has not resumed operations, the court said:

> The only restraint the statute places upon a relocation of the land after an original location has been made is such as prevents the relocator by his relocation from depriving the former locator of any of his rights. But when, as here, all of the rights of the original locator have been abandoned or forfeited, and no claim of such rights is asserted by the original locator, his heirs, assigns or legal representatives, and the contesting parties to the action concede that all rights that ever existed by reason of such prior location ceased to exist before any relocation of the ground was attempted, then it is clear that, under the statute and its unquestioned meaning, the land was open to relocation in the same manner as if no location of the same had ever been made. . . . In order to complete a valid location of the ground in question the locators were not required to state if the whole or any part of the location was located as abandoned property, because they were not in fact locating the ground as abandoned property, but were locating the ground in the same manner as other public mineral ground is located —that is, as an original location. . . . If the location is located as abandoned property, under the local statute (Paragraph 3241, Revised Statutes of Arizona, 1901) before its amendment, then in that case only the location was required to state the fact. But the statute never required the location notice of an original location so to state.

Proportion of Surface to Underground Men

At 58 different mines in Arizona there are employed 1917 surface men and 7505 men underground, according to the annual report of the State Mine Inspector for 1914. This is at the rate of 1 surface man for each 3.9 men underground. This includes all of the larger operations; also many small ones in which the proportion of surface men to underground men is much greater, and may vary from 1:1, to the average given. At the Morenci mines of the Arizona Copper Co. the ratio is 1 surface man to 4.2 men underground; at the Calumet & Arizona, Bisbee, the ratio is 1:6.5; at the Copper Queen, Bisbee, the ratio is 1 to 12.2; at the Inspiration, 1:4.8; at the Ray, 1:2.2; at the United Verde 1:[illegible]; at the Miami 1:7.4.

Details of Milling and Smelting

Barth Slide Rule for Pulp Measurement

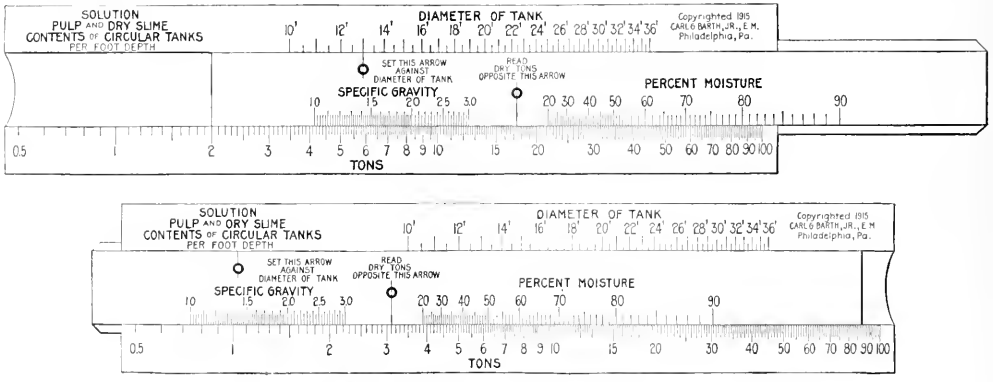
By Carl G. Barth, Jr.*

This slide rule gives the contents, in tons, of tanks ranging in diameter from 10 to 36 ft. and in specific gravity from 1 to 3. The rule consists of four scales—one giving the diameter of the tank by 6-in. intervals, a specific-gravity scale ranging from 1 to 3, a scale giving the percentage of moisture from 20 to 90 and a scale giving the tons of 2000 pounds.

To operate, the arrow is first set against the diameter of the tank, and opposite the specific gravity is read the contents in tons for one foot of depth—if for water, opposite specific gravity 1; if for pulp, of specific gravity 1.5, opposite 1.5. When the dry-slime content is desired, the percentage of moisture contained in this pulp must previously be known. This might be 50%. Remembering or marking the point, read opposite the pulp of specific gravity of 1.5; next move the slide until the number 50, representing the moisture on the scale so indicated, coincides with this, and then read opposite the arrow the tons of dry slime.

As an illustration the problem for which the slide rule is set herein is used. Given a tank of 13-ft. diameter, what is its content per foot-depth in tons of water, tons of pulp of a specific gravity of 1.5 having 50% moisture and in tons of dry slime?

Set the arrow against 13 on the scale showing the diameter of tank. Opposite specific gravity 1, read 4.15 tons water. Opposite specific gravity 1.5, read 6.22 tons pulp. Move the slide so that 50 on the scale, showing percentage moisture, coincides with 6.22. Read opposite the arrow 3.11 tons of dry slime.



METHOD OF USING THE SLIDE RULE

*Consulting engineer, 6151 Columbia Ave., Philadelphia, Penn.

Don'ts in the Designing of a Smelting Works

The bare description of the plant of the Ohio & Colorado Smelting & Refining Co. at Salida, Colo., with the dimensions of apparatus and appliances, cannot be very instructive to beginners, nor interesting for those who have been long in the work, writes F. D. Weeks.[1] However, it seems that some of the peculiarities of the Salida plant as originally built should serve to prevent the younger men from making similar mistakes; the older men can get their satisfaction by reflecting that they never did anything quite so far removed from good practice as some of the things done here.

Originally, a brick wall, with a narrow door in front of each blast furnace, was constructed. How the work was to be done behind this wall is not known, but it shows that the designer did not know how to do the work.

The water jackets were held in place by a 12-in. I-beam running the length of the furnace, thus effectually preventing anyone from examining a tuyere or jacket.

The shaft walls on the feed floor were so thick that the feeders were shoving ore into one end of a tunnel and, since the opening was not so wide as the shaft, the ends of the furnace could not be fed except by throwing the charge around a corner—which, of course, was not done.

The proposal to concentrate matte, carrying 20% lead and 5% copper, in a copper-matting furnace was intended to do away with the necessity of buying roasting equipment.

The largest corliss engine on the plant was the exhibition engine at one of the world's fairs held some

[1]Excerpt from a paper entitled, "The Salida Smelter," to be read before the San Francisco meeting of the American Institute of Mining Engineers, Sept., 1915.

years ago. When repairs were needed, it was discovered that this was the only engine of the kind ever built, and the drawings of it were lost; so each repair part called for an accurate drawing.

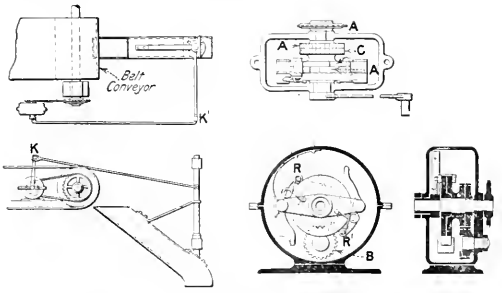
In the track plan of the works, all the ore, coke and limestone had to be unloaded from one track. This track also held the cars which were to be unloaded at the oxide crusher as well as at the sulphide mill. The problem of dispersing some of this congestion was not simple. It was solved by building two trestles in place of one; by having the limestone brought in dump cars so that unloading took little time; and by building an oxide crushing and screening plant on new tracks.

Mechanical Ore Sampler

By J. H. Taylor*

The apparatus here described is not intended to take the place of a sampling plant, but where a mill man wants to have confidence in his sample and the expenditure for a plant to handle 20% of the ore is not warranted, it is much better than hand-sampling.

The device here shown will cut about 0.5% of the ore passing over the end of the belt conveyor, without selection. The sample so taken will not be so accurate for a given day as if taken by cutting 20% each time, but at the end of a week the errors will be largely compensated.



USEFUL MECHANICAL ORE SAMPLER

I have had a mechanical sampler in use for the last 18 months, with excellent results.

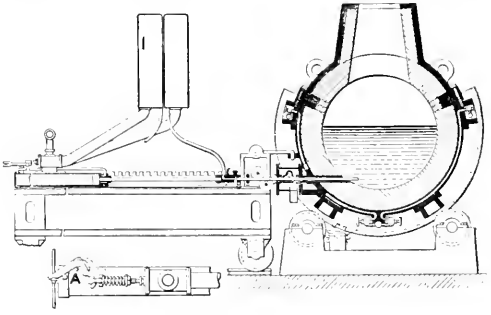
The operation of the device is as follows: The sprocket wheel *A*, gear *A* and disk *A* are keyed to the shaft and driven by a sprocket wheel on the shaft of the driving pulley of the belt conveyor. The gear *A* drives an idle gear *B*, which in turn drives gear *C*. Gear *C* and disk *C* are of one piece. As gear *A* has 31 teeth and gear *C* has 30 teeth, disk *A* will revolve 30 times while disk *C* revolves 31 times. At the beginning of one revolution of each 30, the recesses in disks *A* and *C* will coincide and roller *R* or R^1 will engage disk *A* for half a revolution, when it will be released. Hence a sample will be taken once in 30 revolutions. The lengths of the cranks are such that crank *K* passes through the middle 60° of the 180° while the sample is being taken, so that the increment of the swing of the sample chute is nearly constant, while the stream of flow is actually being cut.

With disks 4½ in. in diameter and a crank 12 in. long this device will successfully sample ore crushed to 4 in. from the end of a belt conveyor 2 ft. wide. The finer the ore the more accurate the daily sample will be, as is usual in mechanical sampling.

*Isabella, Tenn.

Mechanical Tuyere Puncher for Copper Converters

Ralph Baggaley, of Pittsburgh, Penn., has patented (U. S. Pat. 1,135,489) an apparatus for automatically punching the tuyeres of converters and furnaces, the general form of which is shown in the accompanying sketch. An air-cooled punching rod is used, and as many rods are provided as there are tuyeres on the converter, each punching bar being actuated by a separate motor or cylinder. The punching device is mounted upon a movable carriage that may be temporarily fixed in position. The punching rods are operated successively



BAGGALEY MECHANICAL TUYERE PUNCHER

by means of an endless rope, which engages one arm of a bell crank connected with the valve stem of each motor.

The motors or air cylinders that actuate the punching rods are reciprocated by means of air at 70-lb. pressure. This air escaping to a large receiver is cooled by expansion and is then utilized to cool the punching rod. However, water cooling may be used if desired. When repairs are to be made, any actuating cylinder may be stopped by engaging the arm of the bell crank with the special pin *A*.

Recovery of Elemental Sulphur

A new solution for the problem of recovering elemental sulphur from blast-furnace gases is given by W. F. Lamoreaux and C. W. Renwick, of Isabella, Tenn., in U. S. Pat. 1,140,310. Their process consists in passing these sulphur-bearing gases through a red-hot carbon column, which reduces the sulphur dioxide or sulphur trioxide to sulphur. They call attention to the fact that this reaction has its velocity enormously increased by increase in temperature. For instance, in some gases from pyritic smelting, 5% of the sulphur dioxide was reduced at a temperature of 800° C. in 5 sec.; 34% was reduced at 900° in 5 sec.; 63% at 1000°; 91% at 1100°; 96% at 1200°; 98% at 1300°.

It is not possible to keep up a temperature in the coke column high enough to perform this reduction in a sufficiently short space of time without the use of external heat. This is obtained by passing an electric current through the coke column, using this current to obtain the required temperature.

Company Reports

Alaska Treadwell in 1914

The report of the Alaska Treadwell Gold Mining Co., Douglas Island, Alaska, for 1914 shows a profit of $1,351,403 from the treatment of 910,285 tons of ore, before providing for $250,953 depreciation charge. Receipts aggregated $2,435,375, made up of $1,264,945 from bullion, $1,102,617 from sulphurets treated, $24,017 from interest receipts and $43,795 from commercial profits. The following table is a summary of operating costs per ton of ore treated:

Operating costs:	
Mining; development, 5934 ft.; stoping, 301,491 tons	$0.6896
Milling, 910,285 tons	.2572
Sulphuret expense, 13,324 tons treated	.0850
San Francisco office	.0191
London office expense	.0014
Paris office expense	.0003
Legal expense	.0018
Taxes	.0125
Bullion charges	.0113
Total operating costs	$1.0782
Construction costs and repair costs	.0344
Total operating and construction charges	$1.1126
Sundry charges:	
Boarding-house loss	.0057
Dwellings loss	.0115
Wharf loss	.0007
Sundry adjustments	.0603
	$1.1908
Depreciation charged off	.275
Total cost with depreciation	$1.4658

Ore reserves for tons in place are estimated to contain 6,601,086 tons, compared with 4,978,759 in 1913, but ore reserves of broken ore in stopes are estimated at 555,167 tons, compared with a reserve of 1,114,549 in 1913. The decrease in reserves of broken ore in stopes accounts for the difference between tons reported stoped and tons milled. The average value per ton estimated for all reserves was $2.48, compared with $2.67 in 1913.

The average number of men employed per day for the year was 733 and the average wage was $3.51. The assay office made 14,224 assays at a cost of 23.6c. per sample; of these 9748 samples were for the Alaska Treadwell mine and mills. Dividends amounting to $1,100,000 were paid during the year.

Broken Hill Proprietary Co.

The Broken Hill Proprietary Co., Broken Hill, N.S.W., Australia, for the half-year ended Nov. 30, 1914, reports a working income of $1,079,469 from which other charges amounting to $522,971 are deducted, leaving $556,498 balance from which $286,984 in dividends were paid. After adding $53,971 for miscellaneous income, there was a balance of $323,485 left after dividend payments. There were 121,316 tons of ore raised from the mine. The crushing sections of the mills handled 111,489 tons of sulphide ore, producing 18,586 tons of lead concentrates, assaying 64.18% lead and 27.41 oz. silver per ton. The re-treating section dealt with 56,600 tons of tailings and produced 1174 tons of lead concentrates assaying 52.02% lead and 26.33 oz. silver per ton. The zinc-flotation plant treated 78,124 tons and produced 15,851 tons of zinc concentrates assaying 46.86% zinc, 6.41% lead and 12.78 oz. silver per ton.

The lead smelteries produced 43,553 tons of bullion. The Ropp roasters treated 33,564 tons of concentrates and slimes and the Dwight-Lloyd plant 30,849 tons. The refinery dealt with 39,200 tons of bullion, including some concentrates from other companies, resulting in 1,546,238 oz. of silver, 699 oz. of gold, 33,507 tons of soft lead and 309 tons of antimonial lead. The spelter plant handled 7773 tons of concentrates and slimes, and produced 2341 tons of spelter and 342 tons of blue powder.

Alaska United

The annual report of the Alaska United Gold Mining Co., Douglas Island, Alaska, for 1914 shows a profit of $247,938 from 458,314 tons of ore treated, before deducting $81,153 for depreciation of property and plant. Receipts totaled $975,329, made up of $534,407 from bullion sales from the Ready Bullion claim, $431,384 from bullion sales from the 700-Foot claim, and $9538 from interest receipts. Expenditures aggregated $727,391 and consisted of: Operating and construction on Ready Bullion claim, $342,580; operating and construction on 700-Foot claim, $365,272; dwelling loss for year, $1228; coal loss, $1642; sundry adjustments, $16,669. Dividends amounting to $162,180 were paid. The following tables are summaries of costs per ton treated on the two claims:

READY BULLION CLAIM

Operating costs:	
Mining, development, 3569 ft.; stoping, 249,545 tons	$1.0550
Milling, 233,100 tons	.2641
Sulphuret expense, 5700 tons treated	.0933
San Francisco office expense	.0111
London office expense	.0017
Paris office expense	.0003
Legal expense	.0034
Bullion charges	.0100
Taxes	.0104
Total operating cost	$1.4493
Construction	.0204
	$1.4697
Sundry losses and adjustments, less interest receipts	.0218
Depreciation charged off	.1750
Total cost, including depreciation	$1.6665

700-FOOT CLAIM

Operating costs:	
Mining, development, 8528 ft.; stoping, 106,002 tons	$1.2302
Milling, 225,214 tons	.2638
Sulphuret expense, 4409 tons treated	.0797
San Francisco office expense	.0115
London office expense	.0017
Paris office expense	.0002
Legal expenses	.0035
Taxes	.0108
Bullion charges	.0082
Total operating costs	$1.6096
Construction	.0123
	$1.6219
Sundry losses and adjustments, less interest receipts	.0218
Depreciation charged off	.1750
Total cost with depreciation	$1.8187

The Ready Bullion mine is estimated to have 1,835,650 tons of ore in place compared with 1,433,334 tons in 1913; broken ore in stopes amounted to 308,412 tons, compared with 275,328 tons for the previous year. The total ore reserve of both classes amounted to 2,144,062 tons having an assay value of $2.68 per ton.

The 700-Foot claim ore reserves are estimated to contain 2,542,477 tons of ore having an assay value of $2.35 per ton, as compared with 1,281,475 tons at $2.46 per ton, in 1913. The reserve at the end of 1914 was made up of 2,359,495 tons of ore in place and 182,982 tons broken in stopes. Broken ore in stopes shows a decrease of 92,678 tons during the year.

An addition of 30 stamps was made to the Ready Bullion mill and the same number were added to the 700-Foot claim mill. The average number of men employed was 246 at an average wage of $3.49 per day. Employees were charged $25 per month for meals at the company's boarding house and $2 per month for a room in the lodging house.

Mount Morgan Gold

The Mount Morgan Gold Mining Co., Mount Morgan, Queensland, Australia, for the half-year ended Nov. 29, 1914, reports that revenue from all sources amounted to $2,441,574. Expenses charged off were $2,131,332, thereby leaving a balance of $310,242, of which $243,000 was paid in dividends. All ore treated amounted to 179,939 tons, yielding 4,593.58 tons of copper and 58,309 oz. of gold. Of this ore, 13,039 tons were purchased and miscellaneous ores. The mines produced 196,965 tons of rock of which 25,610 tons were waste and the remainder ore. Ore reserves are estimated to contain 1,123,000 tons of high-grade and 1,849,000 tons of medium-grade ore. Development work totaled 2484 ft. and consisted of 1394 ft. of drifts, 110 ft. of recessing, 865 ft. of sinking and 115 ft. of raising.

The new smelting furnaces were started in July. The present cost of coke per ton of Mount Morgan ore smelted is $2.19 but this cost it is expected will be reduced. The handling of flotation concentrates has been a source of trouble on account of their fineness. Laboratory experiments indicate that this trouble can be overcome. The following table gives details of concentration results:

	Weight, Tons	Assays Copper, %	Assays Gold, Dwts.	Recovery Copper, %	Recovery Gold, %
Ore treated	31,274	2.365	5.36	...	...
Table concentrates produced	5,993	3.29	11.44	26.68	40.89
Flotation concentrates produced	3,026	13.94	18.85	57.02	34 00
Total concentrates produced	9,019	6.86	13.93	83.70	74.89

The working cost of Mount Morgan ore treated, inclusive of development and estimated realization charges, amounted to $11.49 per ton.

Le Roi No. 2

The Le Roi No. 2, Rossland, B. C., for the year ended Sept. 30, 1914, reports that as a result of mining operations $39,386 was remitted to the London office of the company. The mine produced 43,908 tons of rock, consisting of 22,479 tons of mixed ore, 1689 tons of second-class ore, 5689 tons of mill ore and 14,051 tons of waste. After hand-sorting, this tonnage was disposed of as follows: 17,566 tons of shipping ore, 12,113 tons of milling ore, 11,178 tons of waste to dump and 3051 tons of waste to fill old workings. Stoping costs totaled $95,089, or $3.32 per ton of ore. Diamond drilling amounted to $19,957, or 70c. per ton of ore. Mining costs in all aggregated $4.02 per ton for the following charges: Ore production, labor, 83c.; explosives, 35c.; illuminants, 3c.; sundries, 6c.; ore sorting, 19c.; general expense, 47c.; power plant, labor, 10c.; supplies, 49c.; mine general, labor, 70c.; supplies, 10c; diamond drilling, labor, 35c.; carbon, 21c.; supplies, 14c. Depreciation amounting to $2.51 was charged off, but not included in the costs just stated.

The gross value of 17,014 tons shipped was $20.19 per ton, made up of $12.13 in gold, 93c. in silver and $7.13 for copper. The mill concentrated 12,170 tons of ore averaging 0.132 oz. gold and 10.44 lb. of copper per ton. From this ore 1322 tons of concentrates were produced containing 0.751 oz. of gold, 0.756 oz. of silver and 20.7 lb. of copper per ton. The smelting charges amounted to $4.98 per ton of concentrates. Development work aggregated about 3794 ft. at a cost of $21.45 per ft. There were 67 diamond-drill holes drilled totaling 12,249 ft. at an average cost of $1.63 per ft.

Broken Hill South Silver

The report of the Broken Hill South Silver Mining Co., Broken Hill, N. S. W., Australia, for the half-year ended Dec. 31, 1914, shows a balance from the working account of $297,199, and receipts of $901,376. After providing for all other charges and income the net balance for the year was $88,965. The mine produced 111,891 tons of ore averaging 15.3% Pb, 7.1 oz. Ag and 14.2% Zn. Of this ore 96.8% was mined on contract, 0.4% by miners on wages, and 2.8% from development work. The average earnings of contract miners was $4.41 per 8-hr. shift and of truckers $3.52 per shift. There were 417 surface employees of whom 404 were in daily attendance and 779 underground employees of whom 734 were in daily attendance. All employees totaled 1196 and averaged 1138 in daily attendance. There were 25,698 cu.yd. of loose material sent below to fill stopes at a cost of 92c. per ton of material used for filling, or 21.6c. per ton of ore extracted. The following gives a tabulation of the classification effected by the concentrating plant:

	Net Weight, Tons	Proportion	Assay Value % Pb	Assay Value Oz. Ag	Assay Value % Zn	Proportion of Metal Contents, per Cent. Pb	Ag	Zn
Concentrates	20,375	18.1	64.9	21.6	8.3	76.7	54.9	10.6
Tailings:								
Zinc	69,943	61.9	3.1	3.3	16.9	12.5	29.0	73.8
Quartz	5,942	5.3	1.7	1.6	4.1	0.6	1.1	1.5
Slimes	16,490	14.7	10.8	7.3	13.7	10.2	15.0	14.1
Total ore	112,750	100	15.3	7.1	14.2	100	100	100

Working costs amounted to $4.88 per ton and consisted of $3.15 for mining, 22c. for filling stopes, 49c. for development and $1.02 for concentrating. Total mine cost per ton of concentrates was $27.56. In treating this ore 26,675,000 gal. of water was consumed.

Van Roi Mine

The Van Roi Mining Co., Silverton, B. C., for the year ended Sept. 30, 1914, reports that the mill ran 3457 hr. and treated 16,025 tons of ore averaging 13.85 oz. Ag, 2.69% Pb and 6.64% Zn. Lead concentrates to the amount of 588 tons were produced, averaging 192.08 oz. Ag, 54.75% Pb and 11.15% Zn per ton. Zinc concentrates produced amounted to 1096 tons, averaging 51.91 oz. Ag, 3% Pb and 39.47% Zn. The cost of mining was reported at $2.57 per ton and $1.61 for concentrating. Development work consisted of 2087 ft. at an average cost

of $13.66 per ft. The average cost of drifts was $13.04 and raises, $15.42 per ft. The results of development during the year did not justify any further expenditure in this direction and no attempt will be made to extract ore from the mine during the continuance of the European war.

Alaska Mexican

The report of the Alaska Mexican Gold Mining Co., Douglas Island, Alaska, for 1914 shows a profit of $170,202 from the treatment of 233,457 tons of ore, before providing for $25,451 depreciation charge. The average yield was $2.18 per ton of ore. Total receipts were $513,318, of which $238,756 came from bullion sales, $270,267 from concentrates treated and $4295 from interest receipts. Dividends during the year aggregated $144,000. The following table gives details of costs per ton of ore treated:

Operating costs:	
Mining; development, 2952 ft.; stoping, 167,274 tons	$1.0188
Milling, 233,457 tons	.2457
Sulphuret expense, 4330 tons treated	.0798
San Francisco office expense	.0225
London office expense	.0030
Paris office expense	.0005
Legal expense	.0057
Taxes	.0087
Bullion charges	.0082
Total operating costs	$1.3929
Construction	.0211
Boarding-house loss for year	.0062
Dwellings loss for year	.0175
Sundry adjustments	.0328
	$1.4705
Depreciation charged off	.1090
Total cost with depreciation	$1.5795

Ore reserves are estimated to contain 688,738 tons of ore, having an assay value of $2.68 per ton, consisting of 327,426 tons of ore in place and 361,312 tons broken in stopes; compared with 816,882 tons having an average assay value of $2.53 per ton and consisting of 430,939 tons in place and 385,943 tons broken in stopes at the end of 1913. The average number of men employed was 159 at an average wage of $3.28 per day.

Arizona Copper

The report of the Arizona Copper Co., Clifton, Ariz., for year ended Sept. 30, 1914, shows a production of 38,756,000 lb. of bessemer copper. Ore mined from the company's properties amounted to 1,079,950 dry tons and the smelting returns indicated an average contents of 36.17 lb. of copper per ton. About 95% of the ore mined was concentrating ore. Of the copper produced 81.4% came from the sulphide ores and 18.6% from oxidized ores. The financial statements show that the profit from operations in Arizona was $1,100,919. After payment of $119,224 in dividends, satisfying bond interest and other charges and adding other income, the net surplus carried forward for the year was $743,837.

The Humbolt mine produced 525,530 tons of ore during the year. The second-class ore at this mine averaged 2.42% against 2.85% during 1913. The Clay mine produced 140,542 tons of ore of which 695 tons were smelting and 140,017 tons concentrating ore. The production at the Petaluma and Carrasco mines amounted to 17,074 tons of which 5001 tons were smelting and the remainder concentrating ore. The Yavapai mine produced 597 tons of smelting ore, 31,226 tons of concentrating ore and 5191 tons of pyrites. The Longfellow North Extension mine production amounted to 61,433 tons concentrating and 1360 tons of smelting ore. The Coronado mine produced 145,352 tons of concentrating and 7756 tons of first-class smelting ore. The Metcalf mines produced from surface and underground 87,297 tons of oxide and concentrating ore. The King mine produced 36,441 tons of which 27,823 tons were sulphide concentrating and 3740 tons oxide concentrating and 4918 tons oxide smelting ores.

The sulphide concentrators treated 932,954 dry tons of sulphide ore of which 76.8% were treated at No. 6 and 23.2% at the Clifton concentrator. The average ratio of concentration was 8.42 tons of ore into one ton of concentrates. The oxide concentrator and leacher treated 87,875 dry tons of ore, producing 5414 tons of concentrates sent to the smelter and 72,649 tons of tailings treated in the leaching plant. Of the total copper production 5.7% came from these ores.

The report states that after the first few months of breaking in the new smelting plant, it has operated smoothly and well. It also mentions the fact that in 1910 the total taxes for state and county purposes in Arizona amounted to $65,060, while in 1914 they were $180,157.

Canada Copper Corporation

The Canada Copper Corporation, Greenwood, B. C., was organized in March, 1914, with an authorized capital of $5,000,000, made up of 1,000,000 shares. There was also authorized at the time of organization an issue of $1,000,000 6% convertible debentures. On Dec. 31, 1914, 600,200 shares of the stock had been issued and 200,000 shares were held for the conversion of the bonds; $600,000 of the bonds had been negotiated, and the remaining $400,000 of bonds and 199,800 shares of stock may be used for future requirements. Under the plan of organization the stockholders of the British Columbia Copper Co. were invited to subscribe for the bonds and to exchange their shares for shares of the Canada Copper Corporation. There were exchanged 444,952 shares of the British Columbia company. The Corporation also holds a first mortgage on the British Columbia Copper Co. to secure a loan of $340,000.

Some details of operating costs at the mines are given in this report. At the Motherlode mine the cost of placing the ore on board the railroad cars at the mine was 85.43c. per ton. This cost includes ore sorting at 1.55c. per ton; development, at 8.7c. per ton, or $5.97 per ft. of work; and diamond drilling at 6.48c. per ton of ore or $2.38 per ft. drilled.

At the smeltery 299,928 tons were handled consisting of 193,542 tons of British Columbia Copper Co.'s ore and 106,116 tons of custom ore. There were 5129 tons of converter slag made and smelted which contained 1627 tons of custom ore and 466 tons of clay. There were 41,026 tons of coke used, which was equal to 13.52% of the entire charge fed to the furnaces. The average grade of the matte was 39.7% copper. The blast furnace slag contained 0.251% Cu, 0.0039 oz. Au, and 0.07 oz. Ag per ton. The average analysis was 41.9% silica, 18% iron and 22% lime. The production of fine copper was 4,146,490 lb.; gold, 14,442 oz., and silver, 63,501 oz. The company closed the year with $181,106 in cash on hand.

Correspondence and Discussion

Proposed Memorial to Doctor Holmes

I have just returned from Washington, where I was in attendance at the funeral of Dr. Joseph A. Holmes, on Saturday. The services at the church and at the grave in Rock Creek Cemetery were dignified, but perfect in simplicity, as befitted his character. The arrangements were made by his loyal friend and assistant, Van H. Manning. The flowers were beautiful, and included a wreath from President Wilson. Each of the bureau's chief stations, Pittsburgh, Denver, San Francisco and Washington, was represented by set pieces, including an exquisite reproduction of the bureau's emblem of the eagle, the crossed hammer and pick and the Doctor's own motto, "Safety and Efficiency." Secretaries Lane, Daniels and Wilson, Gifford Pinchot, and other prominent persons were honorary pallbearers; the bureau division chiefs were active pallbearers.

In talking with a number of Doctor Holmes' personal friends, both in and outside of the bureau, views were expressed that there should be some permanent memorials for so big and unique a man as Doctor Holmes, who covered so wide a range of scientific activities, but most of all who touched the humanitarian side of the thousands with whom he came in contact—from the most successful mine operators to the humblest among the miners. It was a matter of regret to all that he could not have seen in life some of the larger fruits of the work which he inspired among many.

Two plans were suggested which seemed to meet general approbation, including that of Mr. Manning, acting director; and I was informally asked by several to bring the matter before a number of my friends, also friends of Doctor Holmes, who would be in better position than any persons within the bureau to sound out by discussing each in his own special circle of friends in the mining and metallurgical industries the merits of the following or alternative proposals, and the possibility of carrying them out effectively:

The first, the erection of an appropriate monument at the grave in Rock Creek Cemetery, Washington, to be of a simple yet beautiful character, such as the statue of "Grief," by Saint-Gaudens, in the same cemetery, which in itself attracts thousands of visitors. It is thought that there will be tens of thousands of miners, operators, metallurgical workers in the great mining and metallurgical industry, who would gladly contribute the individual small amount needed for such a memorial.

The second, a memorial volume, to contain: (1) A sketch of Doctor Holmes' life; (2) views of his work by a number of selected persons, each representing some phase of the professions and industries with which Doctor Holmes has had to do, such as safety in mining, conservation and efficiency in mining and metallurgy, educational work, geology, as a friend of labor, and as a man; (3) resolutions of various societies and associations, which are now beginning to pour in to the bureau, and to his family; (4) selected writings and addresses by Doctor Holmes. The volume to be carefully edited by some friend of Doctor Holmes who has literary ability, and to be handsomely bound.

It is believed that there would be thousands of subscribers, who for a moderate subscription would at once do honor to Doctor Holmes' memory and at the same time furnish themselves with a book which each would be glad to possess.

It has seemed to a number of those with whom I talked that both the above proposals could be carried out, the first by a large committee under the leadership of some prominent person who would be in position to give some of his attention to it; the second project to be undertaken under the auspices of one of our national engineering or chemical societies, such as the American Institute of Mining Engineers, though of course without financial obligation, the subscriptions in cash to be first obtained. The assembling of the various engineering societies in San Francisco in September would be an admirable time to bring this matter to a climax; but it is well that both the projects, if they seem feasible, should be started as soon as possible.

The replies will probably throw some light on the best manner of proceeding. It will be appreciated that it would not be possible for anyone connected with the bureau to follow the matter up to a finality, but I know all the bureau men will do all they can in a personal, private way to assist those or any other projects to honor the memory of a man who was so much beloved by every one of them.

GEO. S. RICE, Chief Mining Engineer.
United States Bureau of Mines.
Pittsburgh, Penn., July 19, 1915.

Recent Progress in Flotation

I have noticed in the *Journal* of May 29, 1915, an article by O. C. Ralston and F. Cameron on ore extraction by the so-called oil-flotation process which seems to be quite to the point on the question. May I add a few suggestions on what is worth while. I commenced in the oil-refining business almost at the first of refining petroleum, extracting all of the many products, and became interested immediately in the oil part when oil flotation of minerals first came out.

I concluded then as I do now, that complete success must depend upon holding the temperature of the oil at all times the same as the temperature of the ore and mill water used, or as the atmosphere, by interlocking automatic temperature gages. The oil should be held in something like an oil still, so that the temperature of the whole contents of the still can be changed quickly to correspond with the atmosphere, ore and water. Nothing is more susceptible and sensitive to heat and cold than oil.

A practical oil refiner would surely build his stills and appliances to adapt his oil closely and quickly to

the temperature of the mill whether run at midnight, midday, or in wet, damp, cold or stormy weather. Without doing so, the tailings value is bound to go up and down and the extraction be unsatisfactory.

JAMES A. FLEMING.

Globe, Ariz., July 22, 1915.

The Case of Spelter

Producers and sellers of zinc, known in the trade as spelter, are taking advantage of the lull following spelter's advance to unprecedentedly high prices to make careful inventory of the situation. The important query current in zinc circles is: "Will the war demand for the metal be sufficient to absorb the very considerably increased production which is on the way, and will it be able to make up for the falling off in the peace demand for spelter?"

Action brings reaction. The shutting off of zinc supplies from Germany, Austria and Belgium, producers of 50% of the world's spelter, and the demand for the metal by makers of war munitions produced a temporary pinch in the supply which drove its price from about 5c. to nearly 30c. a lb. The importance of the three nations mentioned as producers is seen from the following table, which gives their 1913 spelter production in tons of 2000 lb.:

	Tons
World's production	1,100,000
Germany	312,000
Belgium	218,000
Austria	24,000
Total	554,000
Consumption of these three nations	387,000
Available for export	167,000

With 167,000 tons or 334,000,000 lb. of export metal cut off from the world's sources of supply at one fell swoop, higher prices were inevitable. Fear of a corner rather than an actual corner impelled manufacturers, especially those with war contracts, to rush into the market and bid for the metal almost without regard to price. Undoubtedly they bought more metal and paid much higher prices than the situation warranted.

Since the war began our exports have averaged and are still running at the rate of 10,000 tons per month, or only 120,000 tons per annum. Apparently the warring nations do not need now as much as they required in peace times. The requirement now is chiefly for brass. To make brass two tons of copper are used for every ton of spelter. We have no statistics of copper consumption, but we have statistics of copper exports. They have fallen off, which confirms the theory that less rather than more spelter is being used abroad.

Two important reactions followed the abnormal advance in price as inevitable corrollaries. The first was a sharp decline in what may be termed the peace demand for the metal and the second was a tremendous stimulation of production. Galvanizers who in normal times use 60% of the spelter consumed in the United States, doing business on comparatively narrow margins of profit and unprotected by the large profit margins of war orders, simply could not afford to pay the piper. It is conservatively estimated that the demand from galvanizers has decreased at least 50%, or, say, 100,000 tons per annum.

Producers, fired by the golden lure of prices such as no man has ever seen before, and probably never will see again, are straining every nerve to increase production. Smelteries are operating at capacity, thousands of additional workmen are busy in these plants and at the mines, and millions of dollars are being spent in enlargement of existing zinc smelteries and the building of new ones.

The Steel Corporation is building two large plants, one at Donora, Pa., and one at Gary, Ind., at an estimated cost of $5,000,000 and with a combined production of 50,000 tons per annum. Together with the corporation's present capacity to produce, this will practically remove from the market this large buyer, whose total consumption has heretofore taken about one-fourth of the country's output.

A canvass of the zinc smelteries of the country shows that the operative capacity at the end of 1914, which amounted to 114,000 retorts, as shown by Government survey, has been or will be by Jan. 1 increased to 154,000 retorts. A low estimate of the capacity of these retorts to produce zinc is 4 tons per annum, or, say, a net annual output of at least 600,000 tons. Theoretically the capacity is really about 10% in excess of this quantity, and if anything like current conditions continue to prevail, making it desirable to push operations, at least 650,000 tons per annum can easily be made. This would mean an increase of 300,000 tons over last year's production, thereby making up for the loss of shipments from Germany, Austria and Belgium, with 133,000 tons per annum to spare.

Under these circumstances it is only a matter of time, and a short time at that, when an equilibrium between supply and demand will be reëstablished. When the war is over and Europe is again producing and exporting spelter, this country will find itself with a smelting capacity two to three times greater than any possible demand. Then will come a struggle for existence, with the fittest surviving, and an era of low prices resulting from keen competition such as threatened bankruptcy to many concerns before the war.

Perhaps this readjustment, which is bound to come and which will eliminate the weaker producers, is one good reason why the zinc companies are going slowly in the matter of distributing the large surplus which they are piling up in these piping times, and why conservative investors feel that current prices for zinc shares have sufficiently discounted the situation in spite of present plethoric profits.

J. P. B.

New York, July 29, 1915.

Drilling Campaign of the Consolidated Copper-mines Co.

Recently returning from an absence of several weeks, in an out-of-the-way place, I find my issues of the *Engineering and Mining Journal* awaiting me. Heretofore I have considered the *Engineering and Mining Journal* to be an un-owned, unprejudiced standard of modern mining.

Were it not for the fact that I am sure that the *Journal* has committed a carelessness, not usually characteristic

of it, I would be tempted to suspect that I had been under misapprehension.

The error occurs in the issue of June 19, 1915 (Vol. 99, No. 25), on p. 1069 and is entitled "Drilling Campaign of the Consolidated Coppermines Co.". The *Journal*, having unfortunately omitted the author of this article, would be held responsible for it by anyone who was unfamiliar with the *Journal's* high standards.

As this before-mentioned article appears to be merely a deliberated and undeserved attack upon Colonel Wall, and in no way represents the facts about the Consolidated Coppermines Co., it would be pre-assumed that the *Journal* is not personally responsible for it. On p. 1070, the resources of the great Morris mine are either deliberately misrepresented, or so diluted with waste, that they give no resemblance to the original values. Concerning the Brooks mine, the location of the drill-holes, as shown in the appended plat, vastly discredits that mine; at no place are the drill-holes (put down by former General-Manager F. P. Mills, of the Giroux Co.), which lie to the south of the Bunker Hill, even indicated. This is a severe depreciation as these drill-holes promised that the orebody of the Brooks-Bunker Hill would swing to the south and meet the large bodies of concentrating (largely native copper) ore which underlie the rich zones of the Alpha mine. Neither are the drill-holes shown to the east of the Bunker Hill, indicating a connection with the orebody which follows along, or overlaps the Butte & Ely line, and connects with the Liberty Pit of the Nevada Consolidated Co.; nor is any mention made of these orebodies. Also, no mention is made of the so-called "Old Glory porphyry ore," which is in no way related to the "territory served by the Old Glory shaft"; a large part of the sampling of which was personally supervised by a United States geologist, and which acts as a connecting link between the Morris mine and the rich Veteran orebody of the Nevada Consolidated Co. Nor is mention made of the orebody penetrated in the neighborhood of the Dewey shaft (independent of "the territory served by the Taylor shaft"). Nor is any mention made of a fairly large tonnage developed in the Butte & Ely property, and allowed by as ultra-conservative an engineer as Henry Krumb, of Salt Lake City. To appreciate fully the seriousness of these discrepancies, I will call your attention to the Giroux ore reserves as estimated above the signature of Thomas F. Cole, in the annual report of the Giroux Consolidated Mines Co. for 1911, and reaffirmed by the annual report of 1912; or even as far back as the annual report of the Giroux Consolidated Mines Co. for 1910.

Since, in this article of unknown authorship, no definite value is claimed for the development of the Alpha-Giroux shafts, I will call your attention to the records of the office of the Surveyor-General of the United States, where sworn statements are given in connection with the patenting of the Mammoth and other groups south of the Alpha-Giroux shafts.

Also, in this same deceptive literature, it is interesting to note that the only apparent method of financing the Consolidated Coppermines Co., is by a proposed sale of bonds; and nothing is said of the one million dollars promised by those most interested in the consolidation, which was the most vital element guaranteed in the formation of the Consolidated Coppermines Company.

I think, when you look into the facts of this situation, you will make haste to correct the unfortunate mistake of bearing the responsibility of an apparent attempt, if not conspiracy, to depreciate a very valuable property.

A. J. Sale.

Battle Mountain, Nev., July 24, 1915.

[It is not unusual for persons who read in a newspaper something that they do not like, or something with which they disagree, to charge that it was put in by someone who "owns" the paper, or in pursuance of a conspiracy, etc. The article with which Mr. Sale finds fault was published as a matter of news, and consisted of the summary of a statement by E. F. Gray, the manager of the Consolidated Coppermines Co., to his directors, followed by a brief account of the annual meeting of the stockholders, and concluded with a summary of what President Boynton said in his annual report. All of this was made clear enough in the article.

Mr. Gray in his report of the ore reserves said: "No allowance has been made for any direct-smelting ores known to exist in the Old Glory, Taylor, Giroux and Alpha shafts, or the territory contiguous thereto, as these openings—except on the 770- and 1000-ft. levels of the Giroux shaft—are at present inaccessible."

There was no animadversion about Colonel Wall. The only reference to him was in the account of the stockholders' meeting, in connection with which it was remarked that "No opposition developed from the fiery attack made on the management recently in a circular by Col. Enos A. Wall." The nondevelopment of opposition was a mere statement of fact. Anybody who read Colonel Wall's circular will concede that the characterization of it as "fiery" was very temperate.

We print Mr. Sale's letter for it gives another side of a controversy that appears to have developed, as to the merits of which the *Journal* offers no opinion. Mr Sale's reference to the Giroux report of 1910 is not a happy one, however, the official figures published therein having been rather emphatically discredited.—Editor.]

Fineness of Crushing for Assaying

Will not the readers of the *Journal* give some data on the cause of the differences in assays produced by variation in the mesh to which the ore is crushed before assaying it? Apparently there is a point of maximum recovery; that is, up to a certain point the assays increase as the mesh diminishes, after which the assays decrease as the fineness of sample increases.

I have always supposed the low results with too coarse ore were due to the collector (reduced litharge) going down through the charge before complete fusion had taken place and that the low results with too fine ore were owing to the introduction of extraneous material from the crushing machinery.

Some weight is lent to this view by the fact that the point of maximum recovery is reached—according to my own experience—at a lower mesh on hard ores than it is on soft. But one man's experience and his time and opportunity for experiment are limited, so I should like to hear of other experimenters' work and conclusions.

A. A. Nason.

New York, July 18, 1915.

Imports and Exports of Metals

The United States returns of exports and imports for May and the five months ended May 31, as summarized below, show considerable change this year, mainly on account of the conditions arising from the war in Europe. The noteworthy changes in the more important metals are the large decrease in copper exports and the extraordinary increases in lead and zinc. In the minor metals the chief changes were a large increase in antimony and a heavy reduction in aluminum, due to the foreign embargoes placed on that metal.

United States foreign trade in the chief metals, other than iron and steel, is reported as follows for the five months ended May 31:

	Exports		Imports	
	1914	1915	1914	1915
Copper, long tons	187,993	134,607	67,761	43,628
Tin, long tons	344	308	19,879	18,308
Lead, short tons	7,858	67,906	10,346	28,607
Zinc, short tons	588	59,263	471	326

Copper includes contents of ore and matte. The imports of zinc ore in 1915 were 40,183 tons, containing 32,362,875 lb. zinc. No exports of ore have been reported in 1915. Exports include reëxports of foreign material.

The exports and imports of the minor metals in the United States for five months ended May 31, as reported by the Department of Commerce, were as follows:

	Exports		Imports	
	1914	1915	1914	1915
Nickel, lb	11,603,325	12,623,241	17,093,496	19,403,608
Antimony, lb	3,122	302,625	6,233,503	7,367,600
Aluminum, lb	5,114	28,772	6,511,104	3,323,275
Quicksilver, lb	6,778	120,112		
Platinum, oz	143		34,548	7,749

Nickel and antimony include metallic contents of ore, matte, regulus, etc. Exports include reëxports of foreign material. Exports of aluminum in manufactured forms, not included in the foregoing figures, were valued at $423,855 in 1914 and $1,933,055 this year.

The imports and exports of secondary metallic products in the United States for the five months ended May 31 were as follows, in pounds:

	Exports		Imports	
	1914	1915	1914	1915
Copper sulphate	6,348,208	9,347,066		
White lead	7,384,563	11,118,184		
Zinc oxide	12,224,857	18,159,460		
Zinc dust	34,212	139,178	2,197,965	770,176
Zinc dross	572,477	4,738,324		

The exports of zinc dust given above are reëxports of foreign material.

California Petroleum Production, First Half of 1915

SPECIAL CORRESPONDENCE

The production of petroleum in California in the first half of 1915 is estimated at 44,600,000 bbl. On this basis the total production for the year would amount to 89,200,000 bbl., which would mean a decrease of 14,800,000 bbl. from the total of 104,000,000 bbl. produced in 1914. This decrease in oil production is directly traceable to the European War. There was in June some prospect, however, that the market would improve, as there was a noticeable increase of shipments of crude oil from the fields to the marketing and refining centers. But there is not at present anything in the situation of marked encouragement to independent producers. The production in June was 7,458,600 bbl., showing a small increase over the May figures. Total shipments from fields in June amounted to 7,662,629 bbl., which was approximately an increase over May shipments of 200,000 bbl. The shipments in June were the heaviest recorded since the war began, but not large enough to diminish stock appreciably. Total crude oil stocks at June 30 amounted to 60,616,289 bbl. The average daily production in June, 1915, was 248,620 bbl. and in June, 1914, was 302,400 bbl. In June, 1914, the prices in San Joaquin fields ranged from 40c. to 75c. per bbl. In June, 1915, the prices ranged from 32½c. to 50c. per bbl. in the same fields. One encouraging feature during the past six months is that the increase in stocks on hand totaled only 2,090,000 bbl., which would not have been possible if the Independent Agency had not insisted upon curtailing production.

World's Petroleum Production

The quantity of petroleum entering the markets of the world in 1914 amounted to 400,483,489 bbl., according to statistics compiled by J. D. Northrop of the Geological Survey. Of this record-breaking output the United States is credited with 66.36%, representing in quantity a trifle less than double the output of all the other oil-producing countries combined. Changes in rank during the year affected only Japan and Peru, the former superseding the latter by a narrow margin.

The accompanying table shows the marketed production of petroleum in the world in 1914, and for purposes of

WORLD'S PRODUCTION OF PETROLEUM—1913 AND 1914

Country	1914 Bbl. (42 gal.)	1914 Per-centage	1913 Bbl. (42 gal.)	1913 Per-centage
United States	265,762,535	66.36	248,446,230	64.59
Russia	67,020,522	16.74	62,834,356	16.34
Mexico	21,188,427	5.29	25,902,439	6.73
Roumania	12,826,579	3.20	13,554,768	3.52

Total	400,483,489	100.00	384,667,550	100.00

* Includes British Borneo. † Estimated. ‡ Includes Formosa. §Includes 600,000 bbl. produced in Argentina.

comparison the corresponding output in 1913. The total world's production from 1857 to 1914 is estimated at 593,262,936 bbl., of which the United States has produced practically 60%.

Mineral Oil in Queensland

The Prime Minister of Queensland, Australia, recently made the following statement as to the deposits of oil in Queensland, about which so much has been said:

It is possible that we have large deposits of mineral oil in Queensland, but, while recognizing the necessity for urgent prospecting for it, the Government considered that before committing itself to the large expenditure which would be necessary to carry out operations, it would be well to obtain the opinion of persons who had special knowledge of the oil fields worked in other parts of the world. On my last visit to Europe I was able to bring the matter before several experts, who, before expressing an opinion, desired information as to the geographical formation of the country proposed to be tested. On my return to Queensland an officer of the Geological Survey was instructed to make a thorough inspection of the Roma district, which from present knowledge is the most promising locality, and his report was sub-

mitted to the experts, and their recommendations are about to be carried out. The acting hydraulic engineer is now on his way to America for the purpose of obtaining personal and practical knowledge of the methods adopted in the oil fields there, and, if he thinks advisable, to secure the services of a thoroughly qualified oilborer as his assistant, and also to negotiate for the purchase of an uptodate oil-boring plant.

Revision of Mining Laws Urged

Revision of Federal mining laws that they may encourage the prospector and not discourage him, as is the case at present, will be one of the paramount issues to come before a special meeting of the Mining and Metallurgical Society of America, which will open in Washington, D. C., Dec. 18, according to Horace V. Winchell, says the Salt Lake *Tribune*. Mr. Winchell arrived in Salt Lake, Wednesday, July 28, in connection with apex litigation. He is chairman of the committees on mining law of the American Institute of Mining Engineers and the Mining and Metallurgical Society of America, and, in consequence, is greatly interested in the present agitation for revision of federal mining laws. He said:

Salt Lake City's Commercial Club and Chamber of Commerce and all other Utah organizations interested in the development of the mining industry in this state and the West, will be asked to adopt resolutions for presentation to the American Mining Congress, asking that organization to make an organized effort to accomplish the revision of Federal mining laws. We are determined to bring this matter before the national congress at its next session in such a direct and forceful manner that it will find it imperative to heed our demands for new and better laws

PRESENT LAWS FORTY-FIVE YEARS OLD

The present laws under which claims are located were enacted in 1872, and since that time they have been in force practically unchanged. These laws were well adapted, probably, to conditions as they existed then, but they come far short in meeting conditions as they exist today. Mining men, generally, have condemned the operation of these laws, and there has been much agitation, but no organized effort to obtain action by Congress which would change the laws so as to encourage the prospector and not discourage him.

At the last session of Congress a bill was introduced in the Senate which received the general approbation of mining men. This bill provided for the appointment of a commission of three to investigate conditions in mining sections and to suggest amendments to the present laws. The proposed act passed the Senate with the hearty approval of the Committee on Mines and Mining, Secretary of the Interior Franklin K. Lane, the director of the Bureau of Mines and of the Geological Survey, and was recommended for passage in the House of Representatives by the House Committee on Mines and Mining. Western representatives, however, did not take the interest in the measure which Western senators did, and the bill died without action.

REVISION ENDORSED BY ALL THE LARGE MINING SOCIETIES

This movement for the amendment of mining legislation has the approval of the various different organizations of mining men throughout the United States. The American Institute of Mining Engineers, the Mining and Metallurgical Society of America and the American Mining Congress all have important committees at work on the subject. It is a matter of really great importance. The last report of the Bureau of Mines calls attention to the relative importance of mining and agricultural industries of the country and shows that although each laborer in a mine or smelter contributes an average of $2000 per annum to the wealth of the nation, each agricultural laborer contributes only $800 in the same length of time. Although the agricultural industry is everlasting and the mining industry is only temporary, so to speak, Congress appropriates thirty-five times as much money for the encouragement and development of the agricultural industry as it does for the mining industry.

In the report it is also shown that 65 per cent. of the freight business of all our railroads is in handling raw and manufactured products of mines, and that the standing of the United States among other nations as a manufacturing nation depends more largely upon mineral products than upon any other. But in spite of this fact it is singularly difficult to legislate wisely in the interest of the mining communties.

ACTION TO BE TAKEN IN DECEMBER

The pertinence of these remarks at this time lies in the fact that there is to be held in Washington, D. C., beginning Dec. 18, a meeting of the Mining and Metallurgical Society of America, to which will be invited representatives and delegates from all Western mining and commercial organizations interested in the development of the resources of the respective communities of the West. It is hoped that the meeting will be largely attended and that matters will be brought through this organized effort so directly and forcefully to the atention of Congress that it will result in the much-needed revision.

It is unnecessary to specify in what particulars revision is required, because every mining man and others conversant with the situation know that the law requiring a discovery of metal in places before a valid location can be made is not only absurd, but operates to discourage the prospector. Mining men universally condemn the apex law, which is the direct cause of so much litigation in all our camps and furnishes such fat fees to attorneys and experts at the expense of the mining companies.

Accident Rate at Various Hours of the Day

The accompanying table of accident frequencies is taken from the Raritan Copper Works *Ingot*, and appears to show the effect of tiredness toward the end of the shifts on the accident rate.

NUMBER OF ACCIDENTS OCCURRING EACH HOUR OF THE DAY

1915	Jan.	Feb.	Mar.	Apr.	May	June	No. of Accidents	Per Cent. of Total
3 (a.m.) to 3:59		1					1	4.

Exports and Imports of Lead

In the *Journal* for July 24, p. 156, was given the statement of lead imports for May and the five months ended May 31, as furnished by the Department of Commerce. The statement is now completed by the report of the exports for the same period. The shipments for May included 15,312 short tons of domestic lead exported and 3021 tons of foreign lead reëxported; a total of 18,333 tons. This makes the full report for the five months ended May 31 as follows, in short tons:

	1914	1915	Changes
Imports	10,346	28,607	I. 18,261
Exports	7,858	67,906	I. 60,048

In 1914 the imports exceeded the exports by 2488 tons; but in 1915 the exports have exceeded the imports by 39,299 tons, an average of nearly 8000 tons per month.

U. S. Bureau of Mines Car Touring Idaho

The itinerary of the Bureau of Mines Car No. 5, in charge of John Boardman, will be as follows for the next two months: Burke, Idaho, Aug. 8 to 14; Mace, Idaho, Aug. 15 to Aug. 21; Success, Idaho, Aug. 22 to 28; Kellogg, Idaho, Aug. 29 to Sept. 11; Wallace, Idaho, Sept. 12 to 15; Spokane, Wash. (shops for repairs), Sept. 16 to Oct. 9.

Editorials

The Independent Powder Companies and Their Chance

The manufacture of high-explosives in the United States has heretofore focused in a small group of big companies. There have been a good many small companies, far more than the consuming public has known. The United States Bureau of Mines not long ago listed 29 manufacturers of high explosives in the United States. Most of the small producers, however, have hid their light under a bushel. Their product has gone chiefly into local consumption. Talk with mining men generally—the great consumers of explosives—and few can tell the names of any dynamite-manufacturing companies other than those which arose through the dismemberment of the so-called powder trust.

The big companies are now absorbed in filling their great war contracts, in supplying high explosives to the armies of Europe. They are making fabulous profits, selling for about $1 per lb. what costs them about 30c. to make, so it is said; and the quotations for their shares have soared. While they are thus engaged there is a remarkable chance for their competitors, large and small, to make themselves known and capture a large share of the domestic business. For this there is every inducement. The peaceful business is not immediately so profitable as the military business, but it is more permanent. With mining going on at the high rate at present—copper mines, lead mines, zinc mines and gold mines being worked at their utmost capacity, while iron mining is rapidly rising to normal—there is no sense in anybody shutting his eyes to the possibilities of expansion with the excuse that times are dull.

It is not healthful for any industry to have its supply of an essential commodity centered in one place, or in only a few. More active competition in the supplying of dynamite would be welcomed. Every purchasing agent likes to shop and the existence of shopping tends to improve not only the feelings of the shopper but also the product that is offered to him. If, however, manufacturers want to give the shopper a chance to shop, they have got to let him know about themselves—they have got to kick the bushel off their light. In other words, they've got to advertise.

Those engineers who have broken away from the traditional routine and have tried the dynamites manufactured by the smaller independents find that, though less well known, they do work equal to the old standard brands, that their technical divisions are equally keen to supply the right powder to suit their customers' varying conditions, and that almost invariably the independent powder can be bought for less money. The mining engineers would welcome the widening of their field by the independents for the further reason that the restrictions of some of the dismembered companies have too often been irksome and the subject of complaint.

New Metallurgical Construction

With the practical completion of the New United Verde and Miami copper smelteries, the Inspiration and the Alaska Gastineau mills, the Anaconda and Chuquicamata leaching plants, the Rose Lake and Langeloth zinc smelteries, an extensive program of new construction begun two or three years ago is drawing toward a close. Several of these plants, however, are still lacking their final units, and work on these will be going on during the remainder of 1915, and even in 1916. Among such plants are the Inspiration, Chuquicamata, Alaska Gastineau and Langeloth, which will engage the attention of their builders for a long while yet.

The building of new metallurgical plants is, however, a never-ending process. About as fast as one group is completed another is started. The doubts and uncertainties of the first nine months following the beginning of the war caused a halt, but things are now active again, and probably metallurgical building is going on at as high a rate as previous to the war.

First and foremost is the reconstruction of several of the Anaconda plants, carrying out plans that involve the expenditure of millions of money. In gold milling, the Alaska Juneau mill is the big thing; in zinc smelting, the Donora and Gary plants of the Steel Corporation; in copper metallurgy, the leaching plant of the New Cornelia company. The Tacoma Smelting Co. is adding largely to its electrolytic refining capacity.

There are a great many small plants being put up in all directions, especially to supply the minor metals and various commodities whereof the prices have risen to high levels. In such operations speed of construction is a highly important consideration, and it is to be expected that many old records will be broken.

American Zinc Smelting Capacity

The recent editorial in the *Journal* on the subject of increased zinc-smelting capacity in the United States elicited some corrections from well-informed quarters, the general tenor of which was to show that the *Journal's* estimate was too low. This was not surprising. There appears to be an aversion on the part of the smelters who have been making increases to letting it be known, wherefore tentative lists are likely to be characterized by important omissions.

The following is a revised estimate: At 12 works listed Jan. 1, 1915, new retorts to the aggregate of 16,762 are being added. Five old works, not then listed, have been put in operation, with a total of old and new retorts amounting to 6601. Three new plants are being built with a total of 14,160 retorts. Therefore the total addition to American zinc-smelting capacity will be about 37,600 retorts, corresponding to capacity for about 160,000 tons of spelter per annum, which will give a total

smelting capacity for the production of about 660,000 tons of spelter per annum.

The new capacity will probably become available to its full extent a good deal sooner than was previously estimated. It turns out that the United States Steel Corporation is building not only at Donora, Penn., but also at Gary, Ind. It is said that the production of spelter at Donora is to begin about Nov. 1, and at Gary about Jan. 1. If those dates are lived up to, all records in building smelteries fired with coal will be surpassed. The managers of the Steel Corporation appear to have confidence in this inasmuch as its purchasing agent is reported to be buying no spelter for delivery after November. It is clear that these new plans are going to put the zinc-smelting industry into a new phase. When the largest consumer—a concern that uses about 110,000 tons of spelter per annum—puts itself into a position to supply about 70,000 tons of its requirement there will be a void in the general market that it will not be easy to fill.

*

Nevada Consolidated

About eight years after beginning production, the Nevada Consolidated company is taking steps to obtain ore from its Ruth mine. Heretofore its production has been made by the Eureka, Hecla and Liberty pits, with a little coming from the Veteran mine, which, however, has lately been idle. The Veteran orebody is relatively small and mining it is relatively costly, but the extraction of ore from it will be resumed later. The Ruth mine has a large body of high-grade ore, comparatively speaking. It will be mined by underground methods, which in this case figure out a little cheaper than stripping and steam-shoveling.

The Nevada Consolidated is an excellent example of the principle that great, flat-lying orebodies are usually underestimated. In the Eureka, Liberty and Hecla pits the fringes of the huge ore mass have been found to extend outward farther than ever was reckoned. A result is that after eight years of ore extraction this company is still able to figure its ore reserves at a larger quantity than ever. However, the average grade of the present ore is lower than was originally reckoned and the cost of producing copper from it has increased, though not in direct proportion to the diminution of grade of the ore which has been partially offset by improvements in the arts of mining, milling and smelting.

*

Mining Shares of No Par Value

The Kennecott Copper Corporation, the shares of which were recently introduced to the public, is unique in having a capitalization of shares which have no par value. This is a good idea to follow in the organization of mining companies. In former times it used to be the custom to capitalize a mining company at $100 per share, let us say, and offer the stock at $10 per share, the promoters and the public both hoping that development in the mine might cause the stock to grow up to its par value. Sometimes it did, but more often it did not, causing the stock to look rather ridiculous ever afterward.

In the more modern cases of the porphyry coppers the idea was to capitalize at the real value in the young days of the mine. Thus, Miami was brought out when it had about 2,500,000 tons of ore developed and the shares were made of $5 par value. As the known ore resources of the mine gradually increased to about 20,000,000 tons, the value of the stock increased more or less in proportion thereto, and in fact that company is now paying dividends at the rate of $3 per share per annum, which is 60 per cent. on the par value. This experience (that of Utah, Chino, Ray, and the rest of the porphyry coppers are similar) causes persons inexperienced in mining to wonder. In fact, the par values of these securities ceased long ago to have any significance (except for Federal- and state-taxation purposes). It would have been just as well if they had not been marked with any par value in the first place.

*

Metal Loss in Copper Slags

The important subject of metal losses in copper slags is taken up this week by Frank E. Lathe in the first of three articles dealing with the principal source of loss in copper smelting. Mr. Lathe reports the result of a long series of investigations of the Granby slags, and the conditions under which they are formed. While primarily concerned with the conditions at Grand Forks, he also made examinations of slags from other works, and his article is one of the important contributions on this subject and will, we feel sure, receive careful attention from copper metallurgists. The first installment deals almost entirely with a review of the literature of the subject.

After an exhaustive examination of the losses in copper slags, Mr. Lathe has come to the conclusion that in most instances improvement can be effected by a careful study of conditions. It may be mentioned that he dismisses as unimportant the loss from dissolved cuprous sulphide, and considers that the two great factors are suspended matte particles and oxidized copper. After examining many Granby slags and others from various works, he concludes that the loss from oxidized copper amounts to one-half or three-quarters of the total loss in the slag.

At many plants the metallurgists get into a sort of auto-hypnotic state with respect to the metal content of the slag, once its tenor has been established at what is regarded as the practical minimum with the equipment at hand. The metallurgist in charge may have a theory that a little more settling or some other slight change in practice would reduce the metal losses in the slag, but as this may be only a theory, in support of which he can submit no incontrovertible evidence, he hesitates to ask his directors for an appropriation for experimental purposes. And even while he hesitates, he perhaps receives instructions to proceed with some less promising experiment that has appealed to the vision of one of the lay directors of his company. The metallurgist, after having studied his slag losses and having become convinced that they are about as low as possible with the equipment available, eventually directs his efforts toward keeping the metal tenor of the slag at the conceived minimum.

The Granby Co. attacked the slag-loss problem in an aggressive way and made a decided betterment in this practice by deepening its furnaces and improving the settling conditions. The problem was studied persistently over a series of years, and the results at the Granby works, where over a million tons of slag is produced annually, are noteworthy. Every 0.01% of copper saved from the slag represents an amount equivalent to 200,000 lb. of metal per year; in other words, the 1914 practice at Grand Forks was better than that of 1907 by 2,640,000 lb.

At many other works the study of the slag losses on an exhaustive scale would probably repay the expense. The metallurgists in most instances are handicapped by the prevailing equipment, but were it shown that a marked saving could be made annually the funds would probably be forthcoming for such changes as were desired. At all events, we think that the subsequent installments of Mr. Lathe's article will stimulate metallurgists to an examination of their slag losses to see if only the irreducible minimum is going over the dump.

The index for Vol. 99 of the *Engineering and Mining Journal* will be mailed with this issue. Any subscriber not receiving a copy of it should notify the subscription department at once.

BY THE WAY

The Allis-Chalmers Co. is not so well known in Wall Street as it is in the mining industry. The following story is from the New York *Sun*:

Allis-Chalmers used to be described for the sake of convenience as the company which made everything in the world except money. But now that it is a war stock nobody alludes to it flippantly any longer. A broker just back from a holiday met one of his old customers. "Say, what is this 'war bride' they call Allis-Chalmers?" he called out. "Why?" asked the broker. "Oh, just curiosity. Last week I called up your office and they told me Allis-Chalmers was a hot one. So I bought a hundred. Now I have six points profit in it and I haven't the faintest idea whether it's a motor company, a street railway or a combination of barber shops."

A concession which ought to interest some people is now being offered in New York by Belgian parties, who obtained it from the Russian Government some time ago. It is for an electric power and light plant and a trolley line in the ancient and mysterious city of Samarkand. The introduction of the trolley car and electric light in that city of Oriental tradition seems to be an anachronism, but we suppose such things have to come, even if Kublai Khan turns in his grave. Samarkand is now the terminus of one branch of the Russian Transcaucasian R.R., and is capital of the Russian Central Asiatic provinces.

A few years ago the press throughout the country announced the salvation of the lay mining investor through the operation of the so-called "Blue Sky" laws, by which all mining securities offered for sale were first to be approved by a state commissioner—who was sometimes the bank commissioner, often merely a political appointee, but in no case a mining engineer, so far as is known. Shortly after the Kansas "Blue Sky" law was passed the *Journal* commented on the flotation of a certain company which had its prospectus, gold bonds and "guaranteed stock" approved by the "Blue Sky" commissioner in Kansas. Its name does not yet appear in this paper's dividend list, and it is doubtful whether buyers of the guaranteed stock have received their interest guarantees. Recently a correspondent sent in an item about Field's Process Smelter Fumes Co., which proposed to save the "vaporized metallics" and other elements of value in the fumes much better than the regular operators had been able to do it. This company was said to be selling stock to farmers and other residents in Shasta County, California, where there has been much "smoke talk." The "Blue Sky" commissioner of California is reported to have approved the sale of this company's securities. A decision in such matters involves technical judgment and experience. "And he spoke a parable unto them, can the blind lead the blind? shall they not both fall into the ditch?"

July Mining Dividends

Exclusive of the dazzling $25,000,000 stock dividend of the New Jersey Zinc Co., disbursements to stockholders by 38 United States mining companies making public reports reach $11,052,732, as compared with $7,654,337 in July, 1914. Industrial and holding companies allied to mining paid $2,469,821 in July, 1915,

as compared with $3,320,245 in 1914, while Canadian and Mexican companies paid $962,129 as compared with $1,605,950 a year ago.

The totals for the first seven months of the year are as follows: Mining companies, $37,053,776, as against $40,580,220 in 1914; metallurgical and holding companies, $36,633,973, as against $45,034,348 in 1914; Canadian and Mexican mines, $4,497,751, as against $11,500,862 in 1914. The accompanying table shows details of the month's payments.

PERSONALS

Edwin Northey, of Calumet, Mich., has been appointed clerk at the White Pine Mine.

Frank M. Woods has returned to Colorado Springs, Colo., after making examinations at Oatman, Arizona.

Arthur J. Hoskin has been in the Taos district, New Mexico, inspecting placer property along the Rio Grande.

Sir Richard McBride, premier and Minister of Mines of British Columbia, has returned to Victoria after a European trip.

Edwin E. Chase, of Denver, has been making a trip into the northern part of Ontario and will return to Denver this week.

J. A. Durfee has been appointed by the Jones & Laughlin Steel Co., Pittsburgh, to the position of metallurgical engineer.

M. C. H. Little, representing the Lewisohn interests, is sampling the St. Anthony gold mine in the Sturgeon Lake area in Ontario.

Robert H. Stewart, general manager of the Consolidated Mining & Smelting Co., of Canada, is in Eastern Canada on a business trip.

Ivan P. Tashof is at Morenci, Ariz., working on flotation in the mill of the Miami Copper Co. He expects to remain there most of August.

Frank H. Sistermans has returned from his trip to the Piz-Piz district of Nicaragua, and will be at his headquarters in El Paso, within a short time.

Robert S. Lewis, of the University of Utah, has just returned to Salt Lake City from a visit to the mines at Juneau, Alaska and Dawson, Yukon Territory.

D. C. Stapleton, general manager of the Anglo-Colombian Development Co., Ltd., has been in New York for a few weeks and has gone to Omaha, Nebraska.

J. G. Sipprell, formerly manager of the York Ontario, Cobalt, is now in charge of a molybdenite prospect, near Renfrew, Ont., from which high-grade ore is being taken.

Morton Webber, who obtained a commission in the British Royal Field Artillery and was wounded in France, has now recovered and has joined the British forces at the Dardanelles.

Frank J. Hambly, president of the Cerro Gordo Mining Co., has returned to San Jose, Calif., from a two months trip to New York and Boston, returning by way of Toronto, Seattle and Portland.

Walter E. Burlingame announces that from Aug. 1 the business of E. E. Burlingame & Co., asayers and chemists, will be conducted under his name at the old office 1736 Lawrence St., Denver, Colorado.

Dr. A. C. Lane, formerly state geologist of Michigan, but now one of the faculty of Tufts College, Massachusetts, is making a geological examination of the Indiana Mine in the Michigan copper region.

Dr. F. W. McNair, president of the Michigan College of Mines, has returned to Houghton after a visit to Cobalt, Porcupine and Sudbury. At each camp he was entertained by graduates of the college.

Robert T. Hill, who has been engaged in making a geological survey of Southern California during the last three years, spent a few days in New York this week. Mr. Hill has lately been in Washington, working on his report.

P. K. Horner, manager of the Union Minière du Haut Katanga, who has been visiting in the United States for several months, sailed for London on July 31 on the S.S. "Philadelphia" and will return soon to the Belgian Congo.

L. A. Friedman of the Rochester Mines Co., was in San Francisco recently closing his deal for the purchase of the Four-J lease at Rochester, Nev., and to arrange for listing stocks of the mines in that camp on the San Francisco Exchange.

F. A. Thompson, for three years past superintendent of the Triumph Gold Mining & Milling Co., Lumpkin, Calif., resigned Aug. 1, and will spend some time looking into mining propositions in Nevada and Arizona. His temporary address is at Goldfield, Nevada.

David A. Thomas, the British coal operator, has arrived in Canada on a special mission representing the British Minister of Munitions, and is making a tour of inspection of the factories in Eastern Canada, to ascertain their capacity for producing shells and other war supplies.

A. J. Beaudette, of Vancouver, B. C., is now retained by the Pacific Great Eastern Ry. Co. to advise and assist prospectors relative to the development of mining property along the company's line from Vancouver through Lillooet and Cariboo districts to Prince George.

E. J. W. Donahue, of the Locker-Donahue Co., formerly controlling Cuyuna-Mille Lacs, Cuyuna-Duluth, Duluth-Brainerd and other Cuyuna range stock companies has resigned as an official in the above corporations. He intends to devote his time to private interests on the Cuyuna range.

Roy Reynolds has been appointed captain at the Trimountain mine of the Copper Range Consolidated in Michigan, succeeding Captain Richard Bowden. Reynolds was assistant under Bowden. He is a Michigan College of Mines man. Richard Martin, mining captain, who resigned with Bowden is succeeded by Captains Letcher and Lambert, both capable and experienced men.

OBITUARY

Frank W. Heimick, mining man and capitalist, died at his residence, Duluth, Minn., July 19, from pneumonia. He held many interests on the Mesabi Range and undeveloped property on other Minnesota ranges. He was best known locally for his philanthropical activities.

Henry Anthony de Meli died at Catania, Italy, July 20, aged 73 years. He was born in New York and studied at Columbia University, being a member of the first class graduated by the School of Mines. After leaving college, Mr. de Meli became interested in mining properties at Georgetown, Colo., but he retired in 1870 and went to Europe. He had a home in Dresden, Saxony, as well as in Catania.

James W. Weaver, secretary and treasurer Thomas Iron Co., Easton, Penn., who died July 8, had been in the service of the company 45 years. He began as an apprentice in the machine shop at Hokendauqua, Penn., in 1867, at the age of 15. Later he had positions as clerk and telegraph operator at various plants and became secretary and treasurer in 1892. He was also secretary and treasurer of the various railroad subsidiaries of the Thomas Iron Co. His father was a pioneer iron manufacturer in the Lehigh Valley.

Theodore Bryant Comstock died at Los Angeles, Calif., July 25, aged 66 years. He had a high reputation as a geologist and was well known in the scientific world. He was born at Cuyahoga Falls, Ohio, 1849, educated in the public schools of that state and Pennsylvania and obtained a degree of bachelor of agriculture at the Pennsylvania State College in 1868, bachelor of science from Cornell University in 1870, and doctor of science in 1886. He married in 1880. When but 21 years old he participated as assistant and photographer in the Morgan expedition to Brazil, and in 1873 served as geologist and assistant to the Capt. W. D. Jones, expedition into Northwestern Wyoming and Yellowstone Park. He led a scientific expedition into the Northwest Territory of Canada in 1877. Dr. Comstock was also prominently identified with educational work. He was the founder and director of the Kirtland Summer School of Natural History, Cleveland, 1875; founded the department of economic geology, Cornell University, and was professor of geology and paleontology there from 1875 to 1879; founder and director of the Arizona School of Mines from 1891 to 1895, and president of the University of Arizona, 1892 to 1895. He acted as manager and consulting engineer of several mining companies also. He also occupied many prominent official and public positions. He was assistant state geologist of Texas from 1889 to 1891, and contributed many notable additions to knowledge of the geology of that state; was vice-president of the National Irrigation Congress in 1893; secretary and chief engineer of the Los Angeles Board of Public Utilities, 1910 to 1912; director of the Arizona Agricultural Experiment Station, 1894; assistant state geologist of Arkansas, 1887-88. Dr. Comstock was an original Fellow of the Geological Society of America; original member of Sigma Xi; founder of the Cornell Chapter, Delta Upsilon; and charter member of the Mining & Metallurgical Society of America. He was a frequent contributor to many technical and scientific magazines and journals; also to the transactions of the Mining & Metallurgical Society and the American Institute of Mining Engineers. He served as chairman of the Southern California section of the last-mentioned and was one of its founders. "An Outline of Geology," published in 1879, was his work and he was editor of the "Bulletin" of the Southern California Academy of Sciences. He held membership in several local clubs and lodges. No immediate family, except the widow, is left. He was a man of high attainments and untiring industry.

Editorial Correspondence

SAN FRANCISCO—July 28

Gold Production in California for the first half of 1915 is equal to about $700,000 more than the production in 1914 in the same period, or a total for the first half of 1915 of approximately $11,400,000. It is believed the increase will continue in the second half of the year so that the total production for 1915 will probably reach $23,000,000. Surface placer mining increased in production owing to the abundance of water, and the season for hydraulic mining has been extended for the same reason. There was also plenty of water for mill purposes. The dredge-mining industry was prosperous and productive and some new dredges were put in commission, and others that went into commission late in 1914 added to the production for the first half of the present year. There has been a large amount of new mining and metallurgical machinery installed, chiefly in Nevada, Shasta, and Amador Counties. Copper mining has largely improved, chiefly in the mines of the Mammoth Copper Co. and the Mountain Copper Co. in Shasta County. The production of copper was very appreciably reduced in the last half of 1914 owing to war conditions but in the second quarter of 1915, there has been a notable advance in the demand for, and the production of copper. The report of the Selby Smelter Commission in the latter part of 1914 had a good effect upon the farmers who have largely withdrawn from the fight against the smelteries, and there is not great probability that the fight will be effectively renewed. New investments in California mines have not been as encouraging as was hoped for at the beginning of the second quarter of the year. There were some old mines reopened which will probably add to the gold output for the last half of the year. The outlook for production of potash in Searles Lake region is encouraging and there has been some encouraging prospecting done for antimony ores. Quicksilver has advanced steadily in price in the first half of the year but the total production has not increased. Some of the quicksilver mines have increased production but the promised reopening of old mines has not been equal to the expectation in the last of 1914.

Protests of Farmers in Campo Seco District against the Penn Mining Co. have been renewed by application to Governor Johnson. The farmers urge that some action be taken upon the report of the commission appointed by the Governor in 1913. This commission found something wrong with the crops in the various sections it investigated and under the law providing for the appointment, the attorney general is authorized to bring suit against all persons whom the commission reports in violation of the smelter-waste law. This commission made its report about the time that the Selby commission reported, but the findings were never made public. Some persons believe that the findings were not important enough to make public. At any rate there seems to be no good reason why the copper-mining industry should not be made fully acquainted with the results of an investigation which the taxpayers of California paid for; the copper mine operators being among the taxpayers. This subject of smeltery fumes affecting the farms and the farmers in Calaveras and Amador Counties in the region of the Campo Seco smeltery has been presented in the "Journal" a number of times. The most recent mention of affairs in this region referred to a number of suits brought by a law firm in San Francisco in behalf of farmers who really had no complaint to make but were willing that suits should be brought in their names, accepting the proposition of the attorneys that the farmers would be out no expense for filing or trying the suits but would share in whatever profit might be gained through verdicts in their favor. These suits are about ready for trial. In the meantime the Penn Mining Co. has employed experts who are making examinations of soil. In studying the pest subject in the belief that it will be shown that much, in fact most, of the damage done to crops has been done by unfavorable soil conditions and certain pests probably the aphis. It is quite probable that more fact will be brought out in the trial that may be useful in teaching some of the farmers the value of a course in an agricultural college. Much of this land is worn out. It has been tilled to death, and the process has been going on for the last 50 years. The few farmers who practise rotation in crops and the use of fertilizers are still prosperous in spite of the small amount of fumes from the smeltery. It is hardly believed probable that Attorney-General Webb will order suits brought upon the complaints made to the Governor. One thing is certain, the Penn Mining Co. has done everything possible to prevent damage to the crops and will continue experiments until a satisfactory method shall have been adopted. The thiogen process had its first practical demonstration at the Campo Seco smeltery. That process has since been taken over by the American Smelting & Refining Co. and may yet be adopted by the Penn Mining Co.

BUTTE—July 29

In The State First-Aid Contest held at Billings, Mont., July 23 and 24, the team from the Leonard mine in Butte won first prize after having been disqualified from entry in the elimination contests held in Butte. The teams sent from the Anaconda mines were those from West Colusa and Anaconda, and two more from the Washoe and Boston & Montana reduction works. The Leonard mine team went to Billings at its own expense. It had done good work in the elimination contests, but a comparatively slight error spoiled its chances of winning, but because of its interest in first-aid work it decided to go to Billings at its own expense, and there they won the first prize, a silver medal, given by the American Mine Safety Association. The Leonard team was composed of G. Ethier, captain; H. Hagens, J. E. McCloud, W. E. Barraugh, Ryan Gaul and F. C. Deakin.

Members of the United Mine Workers of America, who are employed in the Butte copper mines, must deposit their working cards with the local union of the Western Federation of Miners or they will be rated as labor outlaws. That was decided on at a conference between a committee representing both national miners' organizations in Butte, July 28. There are about 700 men with United cards working in Butte and if they obey the orders of the joint committee they will join the remnant of the local Federation union, which already has about 200 members out of the 12,000 miners working in Butte. Miners, with former experiences fresh in mind, are reluctant to join any union of miners in Butte and the action of the 700 United Mine Workers will be watched with some interest. There is expectation that many of them will ignore the orders of the committee. The conference held in Butte was called to act on the proposition to amalgamate the Western Federation of Miners and the United Mine Workers of America, but the committee decided that the project was premature and impractical at this time, probably because of the discredited state of the Western Federation and its officers. The two organizations will continue to exchange working cards, but that is all.

SALT LAKE CITY—July 30

The New Wage Scale in Bingham which went into effect Aug. 1 is as follows: Machine men, $3.50 per shift; machine helpers, $3.25 per shift; steel miners, $3 to $3.25 per shift; maximum wages to apply only to skilled miners. Timber men and timber men helpers increased 25c. per shift, with maximum for timber men of $3.50 per shift. Hand trammers, $3 per shift. Horse and mule trammers, $3.25 per shift. Horse and mule trammers' helpers, $3 per shift. Nippers, $3 per shift. All other day labor now being paid $2.50 or more per day will receive an advance of 25c. per day; and all day labor, now being paid less than $2.50 per day, will receive an advance of 20c. per day, while the above scale is in effect. The employees of the Salt Lake smelteries and the Bingham & Garfield railway will likewise receive an increase. The new scale is based on a sustained price of 17c. per lb. for copper—New York quotation—and 5.25c. per lb. for lead. About 7000 men are affected. The raise will add about $750,000 a year to the payroll.

Zinc-Producing Properties in Utah in the last three weeks have been able to market ore running as low as 28 or 29% zinc, as compared with a minimum of 30% or over previously. There appears to be a somewhat better inquiry for this ore, as evidenced by the number of buyers, though the prices paid are not high. Twenty-nine per cent. zinc ore is worth about $1 a unit f.o.b. Salt Lake, the buyer paying the freight. The following companies have men in the field: The Granby Mining & Smelting Co., the Empire Zinc Co., of Colorado, Consolidated Ores Co., representing the Edgar Zinc Co., and Beer Sondheimer & Co. The production of zinc ore at present from

Tintic is about 500 to 600 tons a month of carbonate ore; from Park City, 600 tons, all concentrates, and this should be increased in the near future through the operation of two new mills to work tailings. Stockton produces about 200 tons of zinc ore a month—the Hidden Treasure and Queen of the Mills in Dry Cañon being the principal shippers. Ophir is not producing any zinc at present. Bingham is producing little straight zinc ore, though mixed zinc ores are mined and treated by the United States Co. The Horn Silver in Beaver county ships a mixed zinc ore to Midvale. The Cedar-Talisman in Beaver county produces one or two cars of carbonate zinc ore a month. Most of the ores are shipped to Missouri river points and farther east.

JUNEAU—July 17

Fire at Valdez destroyed approximately $800,000 worth of property on July 15 at 4 a.m. Stiff breeze blowing off the glacier toward open water fanned the fire but saved the town on account of the direction in which it was blowing. U. S. Road Commission office burned with maps and records of 10 years' accumulation. Residents of Valdez started to rebuild at once. Only a small part of loss covered by insurance.

KELLOGG, IDA.—July 21

The Stewart Mining Co. has obtained control of the Cœur d'Alene Development Co. by the purchase of 229,000 shares of stock from Frederick Burbidge, of Spokane, and C. W. Beale, of Wallace. The Cœur d'Alene Development Co. was organized in 1899 by Burbidge; it was capitalized for 1,000,000 shares, par value $1. F. Augustus Heinze bought 330,000 shares, which were turned over to the Stewart company in 1908. Since that time the Stewart has been trying to get control, and they now have all the issued stock except that held by Fred W. Bradley, president of the Bunker Hill & Sullivan, Albert Burch, of San Francisco, and Joseph McDonald, former superintendent of the Treadwell mines. The holdings of the Cœur d'Alene Development Co. include 10 patented claims near Kellogg and adjoining the Stewart mine. The company also owns the concentrator now being used by the Stewart, which was built at a cost of $70,000. Considerable development work has been done on the claims and a gross production of more than a million dollars is reported. There is a block of unexplored ground that will probably be prospected at once by the Stewart. The Ontario Mining Co., composed of Stanley A. Easton, general manager of the Bunker Hill & Sullivan mine, M. A. Folsom, and associates, lessees of the Ontario mine, have a working privilege on the lower tunnel of the Cœur d'Alene Co., and are taking out ore under an agreement whereby they must do a certain amount of development work each month.

ASHLAND, WIS.—July 31

On the Gogebic Range the C. & N. W. Ry. officials report extraordinarily heavy tonnage. Thus far, 1,317,000 tons have gone over Ashland docks, as against 1,062,790 for same period 1914.

HIBBING, MINN.—July 31

Militia Has Been Requested by the village council of Hibbing which has asked Governor Hammond to establish martial law in the village. The request has been denied. Iron-mining companies holding valuable property within the village limits have refused to pay $750,000 taxes and the village is without funds to pay police or firemen.

ISHPEMING, MICH.—July 31

Serious Consideration to Leaching Processes to recover copper from the tailings is being given at the present time by the managements of many of the copper companies in Michigan. The Calumet & Hecla company has erected a leaching plant to treat the tails from the new regrinding plant at Lake Linden and is recovering copper by means of the ammonia process. At Winona a 20-ton experimental plant is now being erected to treat the tails, which carry from five to seven pounds of copper per ton. The solvent will be ferrous chloride, hypochlorous acid and chlorine. The copper will be precipitated by iron. The solution is subject to regeneration by the use of salt, 20 lb. of which will be required per ton of tails treated. Laboratory experiments have shown a recovery of 95% of copper in the tails, and it is believed that almost as good results can be obtained in a plant working on a large scale. The Copper Range company is considering a number of different processes for leaching its tails, of which it has a large stock on hand. All of the tails from the White Pine mill are being saved, with a view of leaching at some future time. The oil-flotation process is also being looked into by Michigan companies, and it is thought that it may work at such properties as the Nonesuch, White Pine and White Pine Extension.

HOUGHTON—July 31

The Workingmen Employed at the Isle Royale and the shareholders residing in this district are gratified to learn that the Isle Royale is to remain under Calumet & Hecla management. They realize that the Isle Royale at best is a low-grade proposition at present running under 13 pounds refined copper—and can operate successfully on a low copper market only by extensive tonnages. It is generally believed that the Isle Royale's new stamp mill will be put in running order at a cost of under $10,000 and it will be the most modern and most economical mill in the district. Of course the long haul on the rock tonnage, made necessary by the fact that Isle Royale rock has been milled at Point Mills and at the Tamarack mill since last December, adds materially to the cost of putting the copper on the market. At the same time the affiliation with the Calumet & Hecla interests was the only thing that made it possible for Isle Royale to maintain operations at all during this present prosperous copper-producing period. Two heads now are working at the new Isle Royale mill and the third will be within a month. This new mill was erected in speedy time and is a credit to the methods and ability of the Calumet & Hecla construction crews. The operation of two heads here released the one head at the Tamarack mill. It is supposed that two heads at Point Mills plant will continue on Isle Royale rock and two at the Isle Royale mill. When the third is ready to go into commission it is hoped that Isle Royale will then be in shape to keep five heads going. This will require about twice the tonnage of rock that Isle Royale formerly produced but will be the solution of the Isle Royale problem, no matter what the price of the metal.

JOPLIN—July 28

Rapid Mill Building is being done by three 9-hour working shifts in the construction of the 500-ton concentrating plant of the Haywood Scott Mining Co., at Duenweg, six miles east of Joplin, Mo., this being the first mill in the history of the Missouri-Kansas-Oklahoma district to be constructed in this manner. Powerful electric lights illuminate the grounds while within the mill-building proper there are scores of brilliant incandescent bulbs, making the work after nightfall just as expeditious as in the day time. Night workmen receive 50 per cent. additional wages. The shifts are so arranged that they overlap, each succeeding shift thereby being enabled to pick up the work quickly. Work on the big plant begun about middle of June will be finished by July 31. The Scott mill will have the largest crusher capacity of any plant in the district, two sets of 14-in. crushers and five sets of 36-in. rolls having been installed. In addition there are two sets of 24-in. rolls for grinding chats. The mill building proper is 100 ft. wide by 140 ft. long and so arranged that either half of the equipment can be run independent of the other half, with the exception of the cleaner jig, of which there is only one installation. Electric power is to be used in the operation of the plant. Four sludge tables will be installed at first and others placed in later if necessary. At the ends of all jigs, dewatering screens will be placed, the water being conveyed to four settling tanks, two of which are on one side of the mill and two on the other. High concrete piers hold the mill building well above the ground and underneath the entire structure a concrete floor will be constructed to catch any fine ore that may sift through. This is a decided innovation as the custom that has prevailed throughout the district is to permit the fine ore to settle through onto the ground and when this becomes sufficiently enriched to warrant it, it is cleaned up and milled. The "dog house" is divided into two apartments, both floored with concrete. One is to be used as a dining room, the other as a bath and dressing room. The latter is equipped with ventilated steel lockers, two shower baths and a swimming pool, 15x26 ft. and 5 ft. deep at one end by 6 ft. at the other. This is the first natatorium to be installed in a Joplin district "dog house."

TORONTO—July 31

Information Regarding the Big Duck Lake Gold Area, lying some 13 miles north of Schreiber on Lake Superior, embodied in memorandum has been issued by Dr. Willet G. Miller, of the Ontario Bureau of Mines. Not much development has been done, but superficial sampling shows encouraging results. The J. Johnson claim south of Little Duck Lake gave $7.60 from a sample across 5 ft. The Coco-Estelle claim gave $8.60 from a sample across 4 ft. of quartz and pyrites. The McCuaig claim is said to contain rich gold ore, some of which was hand-picked and shipped during the winter. The Sjolander-McKirdy claims are said to have a large vein which has a pay-streak near the hanging wall. The Eustace claim is reported to have a large vein, samples from which gave 2% copper and 20c. gold.

The Mining News

ALASKA

THE REPORT THAT PLATINUM HAS BEEN DISCOVERED on the hill back of the town has caused considerable excitement in Dawson. A stampede took place from Dawson and the entire hill was located and the assay plants have been running night and day to determine the value of the ores.

CHARLES HERRON (Six Mile, via Seward)—New mill being installed at Herron's quartz property in the Sunrise-Hope district. Mine shows promise.

KENSINGTON (Juneau)—Hayden-Jackling interests said to be planning reopening of these mines near Juneau and construction of 1000-ton milling plant.

ANACONDA COPPER (Whitehorse)—Ore from this property is now being shipped over railroad to Skagway en route to Tacoma smeltery and is first ore to be shipped from Whitehorse district since Pueblo closed down six weeks after beginning of war in Europe.

TREADWELL (Juneau)—Portion of big plant is shut down owing to breaking of shaft at central hoist. Shaft is 20 in. in diameter and 40 ft. long; new one will have to be brought from Atlantic coast before operations can be resumed. This is most expensive delay ever experienced by this company since its operation during which time it is said to have produced over $200,000,000.

ALASKA GOLD (Juneau)—Original hydro-electro power project on Salmon Creek to deliver 6000 hp. is being supplemented by development of another hydro-electric proposition at Annex Creek, which will give 4000 hp. additional. This will give 10,000 hp. for the 10,000-ton mill or at rate of 1 hp. per ton, but operations indicate that this estimate will be reduced to $^3/_4$ hp. per ton actually required.

ALASKA JUNEAU (Juneau)—Consulting Engineer J. H. McKenzie announces plans for the development of Alaska Juneau mine and estimates that by Oct. 1, 1916, all development work to bring tonnage up to 8000 tons daily will be finished. When that work has been finished all hands will be put to widening drifts and crosscuts to 9x14 ft. It is planned to install a 7500-kw. power plant, consisting of oil-fired boilers and steam turbine. Location of plant not yet decided upon.

NORTH STAR GOLD (Fort Wells)—Sixteen tons of machinery and construction materials have been shipped from Seattle for new stamp mill to be installed on this property. Carl Staps, officer of company, will leave for Atlantic coast shortly to place contracts for equipment. Ore on this property averages about $20 per ton in gold and some has run as high as $120 per ton. Property consists of two claims and enough ore, it is stated, has been blocked out to keep proposed stamp mill running for years. Gus Ohm is president of company.

ARIZONA

Cochise County

PRIMOS CHEMICAL CO. is reported to be actively engaged in mining tungsten ores in Dragoon mountains. About 60 men are at work. Ore is sacked and shipped to company's plant at Primos.

RINE PLATE (Bisbee)—Development work in new shaft has opened up $50 ore. Compressor and hoist are to be installed. Property located in Ash Cañon.

Gila County

SLEEPING BEAUTY (Globe)—Arizona Eastern has constructed good approach to Burch spur, which has been repaired, and ore can be carried to point on railroad by 3-mile haul. From there it is not much over three miles to International smeltery to which plant McClure and Miner will ship. They have been delayed considerably in securing teams, but finally have two six-horse outfits working and will soon be shipping. Fifteen men are now being worked at property and force will be increased as fast as faces are opened.

OLD DOMINION (Globe)—At Old Dominion smeltery during July, copper production has been averaging about 50 tons per day; four furnaces have been in operation entire month. Old converter shell, which has been in operation over two years, is still treating entire output of the furnaces. At central power plant new stack is being erected over one of boilers and plans are being made to install new economizers in some boilers. At concentrator daily tonnage has exceeded 600 tons per day for entire month. Some experimental work is being done with new air-flotation machine. Third compartment has been installed in Woodbury jigs at top of mill, with view to improved efficiency and old shaking screens have been replaced with two low Code shaking screens. Big pocket below 16th level, on north side of station, has been completed and is already being used. Its use relieves congestion of cars on 16th level and also of skilful hoisting operations. Small churn drill hole has been put down for ventilation from 16th to the 18th level and others will be drilled in various parts of mine where occasion demands. On surface a 3x3-ft. flume is being constructed to carry water from concrete dam, above Maurel hotel, past old Dominion's property and down to Hamm Ponds, with view to having as little water as possible get into sands of creek for concentrator's workings.

Mohave County

GOLDEN GEM (Cerbat)—Mill being overhauled. Pipe line is to be laid from mine to mill for water supply.

GOLD REED (Oatman)—Main shaft now down below 330 ft. Station is to be cut at 100 ft. L. L. Moore, of Bisbee, is in charge.

Santa Cruz County

AUSTERLITZ (Oro Blanco)—Recent developments in upper levels have opened up some important orebodies. Mill is to be put in operation soon.

SAN JORGE (Alto.)—C. V. Hudson, owner, has opened up wide ledge of copper ore on this property, but is bothered with water. He has commenced a shaft, and will proceed as long as water does not drive him out.

TRENCH (Patagonia)—Now being reopened by sinking a 500-ft. shaft. Property owned by Clark interests, who have organized Trench Consolidated Mining Co., of which Charles Clark, of Jerome, is president. John Hoy, formerly of Butte, Mont., is manager.

FLUX (Patagonia)—This mine lately equipped with mill now in full operation, sending out ore and concentrates at rate of 25 tons per day. Mill is a dry-crushing plant, using Stebbins table, and is reported as running smoothly. An Ambursen tram connects mine and mill and loading bins.

CALIFORNIA

San Bernardino County

TWIN PEAKS MINING CO. (Hart)—Thomas A. Hine, of 100 William St., New York City, has exercised his option on Sunnyside Group of claims, and has organized Twin Peaks company, a New York corporation, to operate same. Pay ore is exposed at four different points on property, and work of sinking 200-ft. shaft will be undertaken immediately. F. E. Browne is manager.

Shasta County

DREDGING GROUND SOUTH OF REDDING acquired recently by Lawrence Gardella, dredge operator, of Oroville. Ground purchased was McCormick-Saeltzer ranch of 2250 acres, four miles south of Redding.

BULLY HILL (Kennett)—Stated experimental zinc plant is entire success and commercial-size plant may be installed.

SPREAD EAGLE (Kennett)—Development work on this group owned by Mammoth Copper Mining Co., is progressing with satisfactory results. Highly mineralized fissure cut recently in main tunnel; drifting for oreshoot now under way.

MAMMOTH COPPER (Kennett)—Stated contract made to sell all baghouse residue to eastern zinc smelter for $8 per ton. Baghouse installed in 1910, at cost of $250,000, on account of state law and farmers' "smoke suit." Since then no market found for residue until recent high price of zinc made product of commercial value. Eighteen to twenty thousand tons have accumulated.

Sierra County

SECRET CAÑON (Downieville)—From shaft being sunk on manganese ledge by George Henk, assays run from $38 to $81 per ton.

SACRED MOUNT (Sierra City)—Cyanide plant installed and in operation by J. C. Folsom upon tailings of many years accumulation, which assays well.

SOVEREIGN (Sierra City)—Morse Bros. and Meany operating under lease are recovering $2.50 per ton, free gold, from roller mill, and $4 per ton additional through cyanidation.

BIGELOW (Sierra City)—Quartz mine owned by W. H. Martin, Nevada City, Calif., bonded to Croesus Mining Co., of New York. Development work under Manager W. B. Pearson, of Croesus Company.

YOUNG AMERICA (Sierra City)—Dump containing 50,000 tons tailings assaying from $1.50 to $2.50 per ton, gold, purchased by Bonlay & Zachert, of San Francisco, who will construct reduction plant.

OXFORD (Downieville)—Vein cut by crosscut shows well, and extensive drifting being done by Cliff Mining Co. who are operating this and Gold Bluff quartz property together under bond. Grant Snyder is in charge.

Sonoma County

SEBASTOPOL MINING CO. (Sebastopol)—Incorporation of company contemplated. Stated that London men are negotiating for purchase of, or an interest in, the property.

Trinity County

DREDGING-GROUND OPTION extended from July 1 to Nov. 1. This option is on 1500 acres ground on Trinity River from above Carryille to four miles below Trinity Center, and some ground up both sides Coffee Creek. Consideration involved stated to be in neighborhood of $1,000,000. Churn-drill prospecting will be resumed under direction of E. A. Wiltsee. Stated $75,000 already expended in work. Placer ground near Igo, Shasta county, will also be prospected by same company.

Tuolumne County

KNOWLES (Sonora)—John Parsons, who recently leased this property, will install mill immediately.

NORWEGIAN (Tuttletown)—W. E. Booker has installed a hoist and small compressor and will put in power drills. Work will be continued on 100-ft. level, where large amount high-grade ore has been mined.

BUCKEYE (Sonora)—Machinery and supplies have been purchased, and grading for mill site and straightening main gangway and rebuilding track in inclined shaft are nearly completed. Compressed-air drills will be used, and steel cars will displace wooden ones.

COLORADO

Boulder County

LIVINGSTON (Sugar Loaf)—Rich gold ore has been struck in vein that years ago yielded famous Nyanza oreshoot on surface. New disclosure is in workings of United Gold Corporation whose officers claim to have 5-in. streak averaging 10 oz. gold, accompanied by 1 ft. running 2 oz. gold per ton.

BRAINERD TUNNEL (Ward)—Years ago, Col. Wesley Brainerd drove adit about one-half mile for drainage and transportation for mines of Ward district. Death terminated his enterprise, relatives declining to push it. With revival of interest in district and success met in various other mining tunnels of state, movement is on foot to revive this project. This adit would cut principal veins of district at depths varying between 1000 and 1500 ft. below outcrops and would shorten railway hauls on ores about six miles.

Chaffee County

TABOR (Monarch)—F. C. Watson and Harry E. Mathews have taken a 10-year lease on this mine which has been closed 30 years through litigation with owners of adjoining Columbus mine. Vein is 10 to 15 ft. thick and carries gold, silver and lead.

Clear Creek County

PRIMOS CHEMICAL (Empire)—Is working 45 men in molybdenite mine in Dyke district about 11 miles above Empire. Crude ore is sacked, packed down hill on burros, hauled to Empire Station in wagons, and shipped to Pittsburgh for treatment.

Gilpin County

OLD TOWN (Russell Gulch)—Iron City Concentrator has run 26-cord lot of ore from Hutchens lease in deepest workings where 20-ft. shoot is shipped without sorting. Lot produced gold retorts weighing 85 oz. and 58 tons of concentrate assaying 1.45 oz. gold and 2 oz. silver.

Gunnison County

CARTER (Ohio City)—Sellers and Watzling, leasing 400 level, shipped 150 tons of $11 gold ore, while Little & Co., leasing 100 level, produce ore running about 4 oz. per ton.

DOCTOR (Crested Butte)—This mine was closed down 15 years ago because of obnoxious zinc content of ore. It is now under lease by group of railroad conductors who are putting it in shape to produce 65 tons of ore per day under selling contract that calls for delivery of 5000 tons of 30% zinc ore before Nov. 1. A 12-mile wagon-road is being built from mine to station of Almont on Gunnison branch of the D. & R. G. Ry. George Runtz is superintendent.

Lake County

PENN (Leadville)—Lamphier Brothers maintain heavy shipments of iron ore—suitable for smeltery flux—and zinc ore.

VALLEY (Leadville)—Warren F. Page continues to push this adit into Prospect Mt. and has reached distance of 1200 ft. According to original estimates, breast is near expected ore-bearing contact in virgin portion of this district.

LILLIAN (Leadville)—This once-famous mine in Iowa Gulch has been idle for years, but J. Clarence Hersey, manager of property, has recently granted several leases and shipments have been resumed. Ore carries carbonate of zinc and free gold.

GORDON-TIGER (Twin Lakes)—Old mill is being remodeled and will be ready to run within few weeks with capacity of 30 tons daily. Manager George W. Boyce has mine workings reopened and in shape to keep mill supplied to capacity. He also has a force of men developing the Bwlchcogh mine and is running its 10-stamp mill.

San Miguel County

SUFFOLK (Ophir)—Mine has been taken over by new company known as Ophir Range Gold Mining Co. and will be operated under management of W. H. Staver with Thomas Ivey as superintendent. Mill will be remodeled and enlarged.

Summit County

FRENCH GULCH DREDGING CO. (Breckenridge)—Dredge is digging in good ground, recovering about $1000 per day. Production during last week in June was over 400 oz. of gold. Hermann J. Reiling, manager, has placed wager that last 15 days of July will show recovery of over $15,000. Accepting rated capacity of his dredge as 2000 cu.yd. per day, this gravel is yielding approximately 50c. per yd.

IDAHO

Shoshone County

NONPAREIL COPPER CO. (Mullan)—Directors of Nonpareil have decide to sell 207,750 shares of treasury stock to raise money for further development. Call has also been issued for bids to continue driving No. 4 tunnel westward along vein. When driven 880 ft. further this tunnel will have depth of 770 ft. and will be directly under promising surface showing.

LOGAN & PIKE (Gem)—Logan & Pike are installing two jigs, a rougher and a cleaner, about three miles above Wallace for purpose of reworking old tailing deposits of Cañon Creek. Tailings carried by creek at present will be avoided as far as possible, as they are too low-grade to yield profit. Operators expect to recover 40 tons of lead concentrates a month.

SILVER MOON MINING CO. (Wallace)—Company owns nine claims on Cañon Creek, adjoining Frisco on north, and containing two known veins, one of which is near creek and other 2000 ft. up ridge. Shaft sinking on the right limit of the creek is down about 140 ft., which makes it considerably below the creek level. Water is handled by bailing without difficulty. The equipment includes a small air compressor driven by a 35-hp. motor, air hoist, and drills.

HYPOTHEEK (Wallace)—It was announced by management on July 22 that shipments of high-grade ore from 900-ft. level would commence within two weeks, a contract having been let for hauling ore to the railway station at Enaville. Survey will also be made at once for tramway from mine to Enaville, distance of 2½ miles. Company has millsite at Enaville and plans erection of mill. Meanwhile high-grade ore only will be shipped, and ore of lower grade stored. Crosscut on 1100-ft. level being driven to vein, which is supposed to be 160 ft. from shaft. As soon as 1100 is opened sufficiently for production, large electric hoist will be substituted for air hoist now in use. Mine will then have ore available for stoping on four levels—500, 700, 900 and 1100.

KENTUCKY

Hopkins County

WESTERN KENTUCKY SMELTING CO. (Dawsonsprings)—Has been incorporated with capital stock $20,000 to develop zinc and lead deposits at Dawsonsprings.

MICHIGAN

Copper

KEWEENAW (Mandan)—Has levied assessment of $1 payable Sept. 1.

NEW ARCADIAN (Houghton)—Is now making a second mill shipment.

PHOENIX (Calumet)—Has levied assessment of $2 a share, half payable Sept. 1 and balance Jan. 1.

LA SALLE (Calumet)—Continues to ship 450 tons of rock per day, most of it coming from No. 1. It is better than La Salle's previous average

QUINCY (Hancock)—Is using steel tubes in conical mills at stamping plant as substitute for pebbles and finds them successful, covering a test of seven weeks.

FRANKLIN (Hancock)—It will be two weeks before Franklin has electric haulage on 37th level in shape for handling rock. A 10-ton skip will be used and shipments then will run to 1200 daily.

CALUMET & HECLA (Calumet)—Regrinding of tailings will commence as soon as power is furnished from Ahmeek mill turbine. It will be at least six weeks before regrinding plant on dredge output can be in running order.

ISLE ROYALE (Houghton)—Third stamp head at Isle Royale mill will be operated Aug. 15 as will also sixth head at Ahmeek mill. Other two heads at Ahmeek will not be put into commission until some later date.

SOUTH LAKE (Houghton)—Shipped two carloads of rock from stockpile to Franklin mill; is beginning of further regular shipments from this property. More drills are going to work and good rock is being taken out.

CHEROKEE (Houghton)—Has uncovered five lodes, by trenching. Two contained a little copper, showing width of 30 ft. They will be opened farther by blasting. Years ago when former organization had charge of work they opened what was supposed to be Winona lode. Captain Dunn had charge but three shafts that were opened were not deep. As matter of fact it is now believed that Winona formation is carried in these newer openings.

MICHIGAN (Michigan)—Recent $1 assessment called by Michigan will not pay outstanding indebtedness. Understood that creditors will permit use of portion—about half—for exploratory work along lines suggested by management. There are two possible opportunities for Michigan, which owns large acreage. One is development and operation of same formation as Mass is working so successfully, dependent largely upon substantial tonnage. The other is development of some of lodes which South Lake has found so rich.

MINNESOTA

Cuyuna Range

CUYUNA-SULTANA (Ironton)—Test shaft now down 100 ft. Soo Line about to construct ½-mile spur to property. Portion of orebody will be stripped.

CUYUNA-MILLE LACS (Ironton)—Work resumed; 175 men will be employed. Company has sold large tonnage of manganiferous ore to Pittsburgh Steel Co.

Mesabi Range

CORSICA (McKinley)—Resumed July 26, employing 200 men.

LEONIDAS (Eveleth)—Last week 1002 cars were loaded out, being largest shipment ever made from a state-owned iron mine.

MONTANA

Madison County

BEAR GULCH DISTRICT—Bielenberg & Higgins mill in Bear Gulch near Twin Bridges, has been started up and will continue operations through season. From 20 to 25 men will be employed at present; number may be increased as conditions warrant. Tunnel is being extended under contract.

Park County

MONTANA SCOTCH BONNET (Cooke City)—In "Journal" of July 3 stated to be 60 miles from Cooke City; should have read 6 miles.

Silver Bow County

DAVIS-DALY (Butte)—Satisfactory progress made in opening orebodies recently discovered on 2500 level of Colorado mine. Last assays showed 5.6% copper and 6½ oz. of silver per ton. About a carload per day is being shipped from 2500 and 1700 levels. Southwest crosscut on which strike was made on 2500 level is being continued to intersect Hesperus orebody.

TIMBER BUTTE MILLING CO. (Butte)—The zinc concentrator of this company is again running at capacity and handling between 400 and 500 tons of ore per day. It confines its operations to output of the Elm Orlu mine. Concentrates are being shipped to the Oklahoma smelters which are under contract to take 6000 tons per month. Attempts to secure additional smelting facilities have so far not been successful, as a result of which company has been compelled to pile up considerable amounts of concentrates awaiting shipment. About 125 men are employed at company's mill.

TUOLUMNE COPPER MINING CO. (Butte)—President Hickey, being of the opinion that operations at the Tuolumne can be profitably carried on at present, sent a letter to stock-

holders a few weeks ago asking for contributions to the amount of $35,000 for resuming operations. Stockholders have volunteered to lend company $20,000, while Mr. Hickey has advanced $5000. The necessary balance of $10,000 will be forthcoming by the time of starting operations by the end of the month. This will mean that from 75 to 150 men will be put to work causing an addition to the Butte payroll of from $7500 to $15,000 per month.

ANACONDA (Butte)—Company has taken lease on Emma mine of Butte Copper & Zinc Co., and holds option to purchase stock of latter company. Emma is promising zinc mine, located in heart of city of Butte, at Colorado and Silver streets. Some time ago Butte Copper & Zinc Co. gave option to American Zinc Co., which was unable to finance deal and it fell through. Lease and option entered into with Anaconda company is for period of five years, with additional five years to be granted upon complying with certain conditions. Combined with lease is option for 88,300 shares of treasury stock and 100,00 shares of owners' stock, at $1 per share. According to agreement Anaconda company is to unwater mine to 800-ft. level and keep it pumped out at that level for 45 days. Anaconda company is at present making thorough investigation of the mining properties at Neihart in Cascade County with view to reopening Neihart camp. Mines in that camp are low-grade properties; ore carries lead, silver and zinc. One of difficulties of camp in past has been presence of large quantities of zinc which, with processes then in vogue, could not be handled profitably. It is believed that by flotation this ore may be made to yield profitable results and it is with this expectation that Anaconda has taken option on mines where large amount of such ore is blocked out.

NEVADA

Clark County

WHALE (Goodsprings)—At distance of 300 ft. development tunnel has intersected main vein, carrying high-grade zinc-carbonate ore, and it is expected that property will begin shipments in near future.

BULLION (Goodsprings)—Construction work on new 50-ton concentrator being rushed; expected plant will be in operation within 30 days. Force at mine has been increased. Only high-grade lead ore is being shipped, pending completion of mill.

GREEN MONSTER (Goodsprings)—After being idle several years on account of difficulties of transportation, large force of men is now at work getting mine in shape for active production. Considerable tonnage of zinc-carbonate ore is blocked in mine and it is planned to maintain monthly production of 500 tons. In conjunction with Azalia Mining Co., motor truck road is to be built through Wilson Pass to connect with Yellow Pine R.R. above Goodsprings.

ORO AMIGO (Goodsprings)—Ore containing 150 oz. gold and 15 oz. platinum per ton has been discovered on upper tunnel level and is now being sacked for shipment. Occurrence is similar to that at Boss mine, where rich gold-platinum ore was discovered last summer and which produced only platinum in United States recovered in 1914 from a lode deposit. Ore occurs along fracture-zone in limestone; gangue being oxidized quartzose material, carrying some copper and considerable iron; mineral carrying platinum has been identified by U. S. Geological Survey as cupro-jarosite. Discovery at Oro Amigo is especially important, since property is situated two miles from Boss mine, and it introduces possibility of further discoveries along zone of considerable area. Discovery has resulted in increased activity in vicinity.

Nye County

TONOPAH ORE PRODUCTION for week ended July 24 totaled 11,137 tons valued at $226,426, compared with 10,307 tons week previous. Producers were: Tonopah Belmont, 3541; Tonopah Mining, 3150; Tonopah Extension, 1820; West End, 1514; Jim Butler, 1100; North Star, 56; and miscellaneous leasers 146 tons.

TONOPAH MINING (Tonopah)—For quarter ending May 31 net earnings of Tonopah Placers Co., $34,67; of which is owned by Tonopah Mining, amounted to $63,005.

OREGON

Baker County

BEN HARRISON (Baker)—Will make extensive improvements to cost $100,000.

UTAH

Juab County

TINTIC ORE SHIPMENTS for the week ended July 23 have exceeded those of any week in two years, having amounted to 193 cars or about 9650 tons of an estimated value of $240,000.

GODIVA (Eureka)—Lead-silver ore is reported to have been opened recently on 200- and 400-ft. levels.

MAY DAY (Eureka)—The 500-ft. level is being worked by leasers, and 800 is to follow. Good profits are being made, and dividend is expected in August.

NORTH CLIFF (Silver City)—Dump of low-grade ore has been sampled, and it is hoped that it can be treated by new mill, which is in process of construction by Tintic Milling Co.

SELMA (North Tintic)—Crosscut from 200 level has been advanced over 100 ft., and face is in limestone showing some mineralization. Six men are working.

SIOUX MILL DUMP (Mammoth)—About 30,000 tons of low-grade ore have been shipped from this dump, purchased by A. S. & R. some time ago, and another month it is thought dump will be exhausted.

EAGLE & BLUE BELL (Eureka)—Bingham Mines Co., controlling this property as well as Commercial and Dalton & Lark mines in Eureka, has acquired Victoria ground adjoining Eagle & Blue Bell through which property work will be carried on.

MAMMOTH (Mammoth)—Will soon begin shipments from dump left on old mill site southwest of Tintic. There are several thousand tons of the material, which is low-grade copper ore, which will be hauled two miles by wagon to tracks of San Pedro railroad for shipment.

TINTIC MILLING (Silver City)—Preliminary work being done for new mill which is to be built here by Knight-Dern interests; and good progress is being made. Machinery from plant of Mines Operating Co., at Park City, is being shipped to Silver City, to be used in construction of new mill.

CHIEF CONSOLIDATED (Eureka)—This company has recently issued a map of Tintic drawn to scale, 800 ft. to the inch, showing holdings of various companies, and table of production of camp from 1877 to 1914. Map shows company's own property in eastern and northern ends of district, which has recently been increased by 250 to 300 newly acquired claims. Latter will be prospected by diamond drilling with view to study of formations and mineralization and locating shafts and tunnels.

Salt Lake County

EMMA COPPER (Alta)—New lens of ore up to 2 ft. thick has been opened in raise above crosscut. In second or south raise silver-lead ore 6 in. thick has been opened.

ALBION (Alta)—Small seams of ore and copper staining show in face of drift being driven from Quincy tunnel of South Hecla to reach Kate Hays fissure. Leasers are mining ore from old workings.

SOUTH HECLA (Alta)—Stock has been listed on Salt Lake Exchange. Capitalization is $500,000, of which 237,839 shares, par value $1, are unissued. Company owns 41 claims comprising 550 acres in Little Cottonwood and Alta district; eight miles from railroad. Twenty-six claims are patented. Development consists of about 14,000 ft. of workings. Ores carry silver, lead, gold and copper. George H. Watson is president. Property is making regular shipments of one carload a day.

Summit County

BIG FOUR EXPLORATION (Park City)—New mill, seven miles north of city began work July 16. Company has added to its holdings by securing lease on lower half of deposits on Homer ranch.

WASHINGTON

King County

UNIVERSITY OF WASHINGTON (Seattle)—College of Mines, Milnor Roberts, dean, will erect coal-washing plant on campus. Plans have been prepared, work expected to start soon.

Pierce County

TACOMA SMELTERY (Tacoma)—Owing to rapidly increasing copper production of Alaska it is reliably reported that Tacoma smeltery will make extensive additions to increase capacity.

WISCONSIN

Zinc-Lead District

CLIMAX (Platteville)—Is unwatering Homestead mine and will operate Acme property adjoining.

HODGE (Platteville)—Ben Webster & Co. is unwatering this mine and will commence milling within next few days.

KLAR PIQUETTE (Platteville)—Mine closed down for two years and said to have been exhausted, has again been placed on dividend basis.

GRANT COUNTY (Platteville)—H. E. Stephens and Chas. Kistler have taken option on this property and are overhauling milling equipment.

POLLARD & SANE (Linden)—Has acquired Hinkle and Kickapoo properties at Linden and O. P. David mine and milling equipment at Montfort.

CANADA

Ontario

CASEY-SENECA (Cobalt)—Plant has been installed and shaft is down 30 ft.

McINTYRE EXTENSION (Porcupine)—This company capitalized at $2,500,000, has been incorporated to take over Pearl Lake property recently acquired by McIntyre.

PRESTON EAST DOME (Porcupine)—Diamond-drilling will shortly be started on north claim of company immediately adjoining Dome, in hope of striking some of orebodies coming in from latter.

GOULD (Cobalt)—Lease of this property owned by Peterson Lake has been turned over to Mercer Silver Mines and operations have been resumed with W. E. Segsworth as managing director and A. C. Bailey, manager.

TOUGH OAKES (Kirkland Lake)—Application has been made to English courts for winding up of Tough Oakes Gold Mines, Ltd., which was formed in England to acquire these claims, but could not meet payments.

TEMISKAMING (Cobalt)—Half yearly report of company says: In order to carry out our policy of deep mining, it was found necessary to install a new hoist. This we expect to have installed and running within 60 days. This hoist will enable us to reach the lower contact between the diabase and the Keewatin formations (a depth of between 1600 and 1700 ft.) and it is believed that as rich values will be encountered at the lower contact as have been developed at the contact above. This work will be pushed forward as rapidly as conditions will permit.

Yukon

CANADIAN-KLONDYKE (Dawson)—No. 2 dredge, which overturned last autumn, was righted and drydocked on July 20, but an accident on July 23 will prevent its going into commission as early as expected. One man was killed and two were seriously and one slightly injured. The yields from the other three dredges have lately been the highest ever recorded. For the week ended July 20, 3407 oz.; July 27, 3436 oz.

SOUTH AMERICA

Colombia

ANGLO-COLOMBIAN DEVELOPMENT (Istmina)—The new dredge completed its preliminary run successfully on July 20 and is now operating regularly near the mouth of the Condoto. The camp name has been changed to Andagoya, Boca de Condoto.

The Market Report

Metal Markets

NEW YORK—Aug. 4

Copper and tin declined during the early part of the week and then rallied. Lead experienced a sharp decline and the course of spelter was steadily downward.

Copper, Tin, Lead and Zinc

Copper—During the early part of the week the copper market was only nominal, there being no buyers but plenty of sellers who made offerings at concessions from day to day. In the latter part of the week some sales were effected, but business was not general. However, there were some inquiries in the market toward the close both from domestic and foreign quarters, and there was a feeling of hopefulness that these would shortly result in business. The pressure of Australian and Japanese copper in the European markets appears to have relaxed and sales of American copper for export were made at about 17.60c., New York. For domestic shipments copper was offered at the close at 17¾@18c., regular terms.

Copper production at Katanga during the first six months of 1915 was slightly in excess of 15,000,000 pounds.

Copper Exports for the week ended July 24 are reported by the Department of Commerce at 11,352,552 lb.; the chief items being, 7,492,788 lb. to France, 1,906,316 lb. to Russia and 1,308,704 lb. to England. Imports were 1,880,454 lb. metal and 981,316 lb. in ore and matte, 2,861,770 lb. in all, chiefly from Canada.

Copper Sheets bring 24@25c. per lb.; no base quotations are made by the principal maker. Wire is quoted at 20@20½c. per lb., carload lots at mill.

Tin—After an early decline this market rallied a little. There were no features of special interest.

Visible Stocks of Tin on Aug. 1 are reported as follows, including tin afloat: London, 7352; Holland 41; United States, excluding Pacific ports, 8691; total, 16,084 long tons, an increase of 157 tons during July.

Lead—Opinion which was optimistic at the date of our last report suddenly turned pessimistic. The price of the A. S. & R. Co. had previously been cut by dealers, but at the beginning of our week of review lead was offered at sharp concessions by outside producers, and on July 30, the A. S. & R. Co. reduced its price to 5.50c. This was immediately shaded by other sellers and on Aug. 2 the A. S. & R. Co. reduced to 5.25c., its competitors following with further cuts, and at the close of the week lead was available in large lots at 5c. per pound. Small sales were reported at that figure and a great deal offered for which buyers could not be found. This lead was offered by dealers, by consumers who wanted to resell, and by producers. The opinion is expressed in the trade that consumers overbought themselves in their recent operations in the market.

Spelter—The course of the zinc market was steadily downward throughout the week. Large supplies are being offered from numerous quarters. Transactions were light. The differential between prices for early and late deliveries contracted futther. At the close contracts for delivery during the remainder of the year, including both near-by and later deliveries, could be made at 14½@15c. There appears to be some speculative spelter hanging over the market and it appears also that certain manufacturers who overbought their requirements and offered their surplus for resale have not yet disposed of all they want to.

Zinc Sheets are in good demand and sales are steady. The base price is $24 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras are charged.

We understand that the U. S. Steel Corporation expects to be able to begin the production of spelter at Donora before the end of this year. However, the production in 1916 will be very small, even if there be no miscarriage of plans.

According to the London "Financial Times," the Vieille Montagne company is running its smelteries in Belgium almost as usual. With a view to keeping the staff together and the works in good order the direction has been treating accumulated concentrates and stocking the zinc produced in default of any facilities for shipping it.

Other Metals

Aluminum is steady and in fair demand, but with no material change in prices. Current quotations are 31@33c. per lb. for No. 1 ingots, New York.

Antimony has been dull with very little business forward. Prices are hardly more than nominal. Ordinary brands being 35@37½c. per lb. For Cookson's 48@50c. is asked.

Quicksilver shows a moderate business chiefly of a small order. New York price is $92@94 per flask of 75 lb. for large lots, $95@98 for smaller orders. San Francisco reports by telegraph $92.50@95 per flask, with a quiet market. London price is rather higher, £18 12s. 6d. per flask being named.

*Nominal.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York, 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

		Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
July-Aug.	Silver	Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos	£ per Ton	Cts. per Lb.	£ per Ton	Cts. per Lb.
29	22⅞	71¼	72⅜	87½	18 64	158¾	158¾	23½	5 09	92½	19 70
30	22⅞	71¼	72⅜	87½	18 64	155	155¼	23½	5 01	92½	19 70
31	22⅞										
2											
3	22⅞	72½	73½	87	18.53	157	157¾	23½	5.04	91½	19 48
4	22⅞	73	74½	87	18 53	156½	157¾	23½	5.04	91½	19 48

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter is subject to 3 per cent. discount. For convenience in comparison of London prices in pounds sterling per 2240 lb., with American prices in cents per pound, the following approximate ratios are given, reckoning exchange at 4 80: £10 = 2.14c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations of £1 = 0.21½c.

Gold, Silver and Platinum

NEW YORK—Aug. 4

Gold and Silver Movement in the United States, six months ended June 30, as reported by the Department of Commerce:

	Gold		Silver	
	1914	1915	1914	1915
Exports	$83,974,535	$7,582,527	$25,510,170	$24,819,297
Imports	30,743,422	144,924,436	12,590,464	14,741,600
Excess	E.$53,231,113	I. $137,341,909	E. $12,919,706	E. $10,107,697

Exports of merchandise for the half-year in 1915 were valued at $1,701,862,297; imports, $860,821,865; excess of exports, $841,040,432. Adding the gold and silver leaves $718,806,220 as the net export balance.

Silver—Under date of July 22 London writes that the silver market shows no animation. The dominant factor is still the very restricted amount of selling from America, which offset the sluggish disposition of buyers. Cables of later date confirm substance of mail better.

Platinum—The market continues quiet and business is moderate, as it has been for some time past. Quotations are about $37@39 per oz. for refined platinum and $41@44 per oz. for hard metal.

Our Russian correspondent reports under date of July 9 that there is no change. In Petrograd there was demand for some quantities for export, but no actual sales. At Ekaterinburg buying from the mines and sales by speculators have gone on as usual. Quotations for crude metal, 83% platinum, are 33,000 rubles per pood at Petrograd; 8.20 rubles per zolotnik at Ekaterinburg—equal to $32.34 and $30.73 per oz., respectively.

Zinc and Lead Ore Markets

JOPLIN, MO.—July 31

Blende, high price, $112; base price per ton of 60% zinc, premium ore $110, medium $107@100; $98@80 lower grades; Calamine, base per ton of 40% zinc, $50@56; average, all grades of zinc, $103.30. Lead, high price, $60.50; base, $60 per ton of 80% metal content; average, all grades of lead, $58.08 per ton.

SHIPMENTS, WEEK ENDED JULY 31

	Blende	Calamine	Lead	Values
Totals this week..	10,649,660	511,400	1,719,700	$627,350
Total 7 months..	332,826,660	28,312,770	50,482,880	$14,418,020

Blende value, the week, $562,890; 7 months, $12,464,080.
Calamine value, the week, $14,530; 7 months, $164,820.
Lead value, the week, $49,930; 7 months, $1,339,120.

PLATTEVILLE, WIS.—July 31

The base price paid this week for 60% zinc ore was lowered to $100 per ton. The base price paid for 80% lead was $60 per ton.

SHIPMENTS WEEK ENDED JULY 31

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	2,138,360	.....	714,800
Year	107,900,580	4,083,160	15,916,450

Shipped to separating plants during week, 5,120,500 lb. zinc ore. Shipments light because of rains.

Iron Trade Review

NEW YORK—Aug. 4

The market is in an unprecented condition for July, usually a dull month. Export orders show a large increase and there is a steady gain in domestic business. Recent price advances are well held and further ones in bars and plates will be made, it is said.

Pig iron is stronger and more business is reported, while in some cases there are larger takings under contract. There is talk, as there has been for some time, of speculaive buying of pig. These rumors are not usually easy to confirm, but there is probably some truth in them.

Imports at Baltimore for the week included 3928 tons of ferromanganese from Middlesboro, England, and 1050 tons manganese ore from Rio Janeiro, Brazil.

PITTSBURGH—Aug. 3

The steel mills are now filled with business, except for a limited tonnage of bessemer which could still be produced, and buyers of some finished products will be urged to take bessemer instead of openhearth, when it can be shown that the former is equally serviceable for the purpose. The delivery promise on new specifications for steel bars has been lengthening rapidly, and is now at a minimum of six weeks. On large steel rounds, for shrapnel, the mills are almost entirely filled for more than six months, but are still in receipt of large orders. A curious result is that they are quite the reverse of eager to accept orders for rails, though they accept them as a matter of trade courtesy. A large part of the rail capacity of the country is now rolling steel rounds for shells.

New orders for steel products have become relatively light, but specifications on contracts are as heavy as ever, and even the increased steel production does not prevent the mills from accumulating shipping orders on books.

Steel prices continue to harden. There are prospects of an early advance in steel bars from 1.30c. to 1.35c. In shapes the 1.25c. quotation has disappeared, the market now being 1.30c., while in plates the tonnage offered at 1.25c. has become limited. Black sheets have stiffened to 1.80c., but this is no higher than the market at the beginning of the year.

Pig Iron—W. P. Snyder & Co. announce their computations of average realized prices, on all sales of Valley iron 1000 tons and over, for July at $13.991 for bessemer, an increase of 24.1c. over June, and 12.959 for basic, an increase of 23.5c. over June. The market has become rather excited and while no large sales have been made in the past week some Valley furnaces have advanced their quotations 50c. on basic and 25c. on bessemer. It is reported that the Tennessee company has advanced its price on foundry iron to $12.50. Birmingham, which means that it has withdrawn entirely from the market, which has lately advanced from $9.50 to $10. Some large purchases in the local market are expected this month, particularly of steel making grades. We quote: Bessemer, $14.25@14.50; basic, $13@13.50; No. 2 foundry, $12.75@13; malleable, $13; gray forge, $12.50@12.75, at Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—The ferromanganese situation is made particularly uncertain by the recent order of the British government, requiring the English producers to carry three months' stock of ore and three months' stock of ferromanganese, and the British consumers to carry three months' stock of ferromanganese. This may seriously affect our imports. On the other hand, however, our imports of ore have been much larger in the past three months than in the first four months of the year, when they were almost negligible. Small prompt lots are held at $100@105, while there is no regular contract market.

COKE

Coke production for the week in the Connellsville region was 367,095 short tons; shipments, 360,852 tons. Production of Greensburg and Upper Connellsville districts was 43,565 tons.

Chemicals

NEW YORK—Aug. 4

The general markets are quiet, and more or less affected by the seasonal conditions.

Arsenic—Only about the usual trade is being done. Supplies seem to be sufficient for all demands. Quotations are about $4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is steady but not particularly active. Quotations show little change, $7.25 per 100 lb. being named for carload lots and $7.50 per 100 lb. for smaller parcels.

Nitrate of Soda—The market is fair for the season, and is steady, with prices unchanged. Quotations are 2.35c. per lb. for spot and for all positions this year.

Pyrites—Imports at Baltimore for the week included 3222 tons of pyrites from Huelva, Spain.

Potash Salts—Imports of potash salts in the United States for June and the six months ended June 30 are reported by the Department of Commerce as follows, in pounds:

	June		Six Months	
	1914	1915	1914	1915
Carbonate of potash	1,385,750	588	11,252,825	8,396,622
Hydrate of potash	740,930	7,000	4,203,568	2,023,942
Nitrate of potash	479,881	.....	1,558,926	6,855
Cyanide of potash	22,400	.....	298,377	828,577
Other potash salts	540,295	11,275	3,244,686	2,075,535

Imports of the crude or manure salts were as follows, in long tons:

	June		Six Months	
	1914	1915	1914	1915
Kainit	17,891	2,860	257,253	6,646
Manure salts	33,151	.....	114,820	12,456
Sulphate of potash	16,473	1,095	37,786	9,901
Muriate of potash	3,000	320	108,759	56,455

The changes were due to the interruption by the war to shipments from Germany.

PETROLEUM

Oil production in California, six months ended June 30, was 44,677,443 bbl. The stocks reported on June 30, 1915, were 60,616,286 bbl., an increase of 2,090,012 bbl. over those at the opening of the year.

Shipments of oil from Mexico in May were 2,378,848 bbl., of which 1,504,629 bbl. went to the United States. For the six months ended June 30, the total shipments were 10,438,528 bbl., a decrease of 212,094 bbl. from last year.

The Mining Index

This index is a convenient reference to the current literature of mining and metallurgy published in all of the important periodicals of the world. We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown, inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order. Coupons are furnished at the following prices: 20c. each, six for $1, 33 for $5, and 100 for $15. When remittances are made in even dollars, we will return the excess over an order in coupons, if so requested.

COPPER

1504—ARIZONA—Progress at the Old Dominion Mine, Mill and Smelter. C. A. Tupper. (Min. and Eng. Wld., June 19, 1915; 5¾ pp., illus.). 20c.

1505—ASSAYING—A Method of Assaying Copper. Arthur Fraser. (Journ. Soc. Chem. Ind., May 15, 1915; 1½ pp.)

1506—CENTRAL STATES—Silver, Copper, Lead and Zinc in the Central States in 1914. B. S. Butler and J. P. Dunlop. (Mineral Resources of the U. S., 1914, Part II; 98 pp.)

1507—CONCENTRATION—Bolivian Copper Concentration by Cia. Corocoro de Bolivia. F. A. Sundt. (Eng. and Min. Journ., July 17, 1915; ¾ p.) 20c.

1508—FLOTATION at the Inspiration Mine, Arizona. (Min. and Sci. Press, July 3, 1915; 4 pp., illus.) 20c.

1509—FUEL—Anaconda Coal-Pulverizing Plant. E. P. Mathewson. (Eng. and Min. Journ., July 10, 1915; 3 pp., illus.) 20c.

1510—HYDRO-ELECTROLYTIC TREATMENT of Copper Ore. Robert Rhea Goodrich. (Advance copy, A. I. M. E., Sept., 1915; 44 pp., illus.) Account of experiments on a porphyry ore from Bisbee, Ariz.

1511—ORE BEDDING and Reclaiming at Copper Smelters. W. A. Clay. (Min. and Eng. Wld., July 17, 1915; 3½ pp., illus.) 20c.

1512—ORE HANDLING—Handling Ore at the Calumet & Arizona Smelter. C. A. Tupper. (Min. and Eng. Wld., July 3, 1915; 6 pp., illus.) 20c.

1513—PORPHYRY COPPERS, The. Percy E. Barbour. (Eng. and Min. Journ., June 26, 1915; ¾ p.) Data on ore reserves, and milling result. 20c.

1514—PYRITIC SMELTING—Beobachtungen beim Pyritschmelzen. R. Stören. (Metall u. Erz, May 22 and June 8, 1915; 12¾ pp.)

1515—SANTO DOMINGO—The Copper Deposits of San Cristobal, Santo Domingo. Thomas F. Donnelly. (Advance copy, A. I. M. E., Sept., 1915., 10 pp., illus.) 40c.

1516—SHAFT-ROCKHOUSE PRACTICE in the Copper Country. L. Hall Goodwin. (Eng. and Min. Journ., June 19, 26, July 3 and 10, 1915; 18¼ pp., illus.)

1517—SMELTER—The British Columbia Copper Co.'s Smelter, Greenwood, B. C. Frederic K. Brunton. (Bull. A. I. M. E., July, 1915, 17 pp., illus.) 40c.

1518—THICKENER—Arizona Copper Co.'s Dorr Thickener. David Cole. (Eng. and Min. Journ., July 24, 1915; 3¾ pp., illus.) 20c.

GOLD AND SILVER—GEOLOGY

1519—ARIZONA—Geology of Gold Road District. Howland Bancroft. (Min. and Sci. Press, July 3, 1915; 1 p., illus.) 20c.

1520—NEVADA—Volcano, a New Nevada Strike. Francis Church Lincoln. (Eng. and Min. Journ., July 10, 1915; ¾ p., illus.) 20c.

1521—QUEENSLAND—The Mount Taylor Gold Mine, Kingston. Lionel C. Ball. (Queensland Govt. Min. Journ., June 15, 1915; 3¼ pp., illus.) 60c.

GOLD DREDGING, PLACER MINING, ETC.

1522—ALASKA—Flume-Type Elevator Dredges in Alaska. Lewis H. Eddy. (Eng. and Min. Journ., June 26, 1915; ¾ p., illus.) 20c.

1523—DEBRIS, A Novel Debris-Dam. Leroy A. Palmer. (Min. and Sci. Press, July 10, 1915; 3¾ pp., illus.) Notes on a dam designed by J. M. Howells constructed at the Omega mine, Nevada Co., California. 20c.

1524—DREDGING COSTS. James Wilson Neill. (Min. and Sci. Press, June 12, 1915; ¾ p.) Data regarding the Oroville Dredging, Ltd., operations completing an article previously published. 20c.

1525—FINE GOLD SAVING—Undercurrents. R. T. Ulrich. (Min. and Sci. Press, June 5, 1915; 1½ pp., illus.) 20c.

1526—METALLURGY of Alluvial Mining. John M. Nicol. (Min. and Sci. Press, June 5, 1915; 4 pp., illus.) Continuation of article previously indexed. 20c.

1527—SAMPLING—Relative Error in Alluvial Sampling. Charles S. Haley. (Min. and Sci. Press, July 17, 1915; 1½ pp.) 20c.

GOLD AND SILVER—CYANIDING

1530—COLORADO—Cyanidation of Low-Grade Sulphide Ores in Colorado.—I. H. C. Parmelee. (Met. and Chem. Eng., July, 1915; 4¼ pp., illus.) 40c.

1531—HOMESTAKE MINE—Notes on Homestake Metallurgy. Allan J. Clark (Bull. A. I. M. E., July, 1915; 20 pp., illus.) 40c

1532—JAPAN—Cyanide Plant at Kushikino, Japan. (Min. and Sci. Press, June 19, 1915; 2 pp., illus.) 20c.

1533—OREGON—The Rainbow Mill, Oregon. W. M. Dake, Jr. (Eng. and Min. Journ., June 26, 1915; 4 pp., illus.) 20c.

1534—REFINING—Electric Furnace for Gold Refining at the Alaska-Treadwell Cyanide Plant. W. P. Lass. (Bull. A. I. M. E., July, 1915; 5 pp., illus.) 40c.

1535—SOLUTION—The Precipitating Action of Carbon in Contact with Auriferous Cyanide Solution. W. R. Feldtmann. (Bull. 129, I. M. M., June 17, 1915; 3½ pp.) Further contributed remarks on paper previously indexed.

1536—SOLUTIONS—The Morro Velho Method of Assaying Gold-Bearing Cyanide Solutions. Donald M. Levy and Harold Jones. (Bull. 129, I. M. M., June 17, 1915; 1½ pp.) Contributed remarks on paper previously indexed.

1537—TUBE MILLING—The Theory of Tube Milling. H. A. White. (Journ. Chem., Met. and Min. Soc. of So. Afr., Mar. and Apr., 1915; 9½ pp., illus.) Discussion of paper previously indexed. 80c.

1538—TUBE MILLS—The Use of Scoop Discharges in Tube-Mills. W. R. Dowling. (Journ. Chem., Met. and Min. Soc. of So. Afr., Apr., 1915; 4 pp.) Discussion on paper previously indexed. 60c.

GOLD AND SILVER—GENERAL

1539—ALASKA—The Juneau Gold Belt. (Alaska and Northwestern Min. Journ., June, 1915; 1½ pp., illus.) 20c.

1540—ARIZONA—Conditions Favorable in Tom Reed-Gold Road District. William P. De Wolf. (Salt Lake Min. Rev., June 15, 1915; 1 p., illus.) 20c.

1541—ASSAYING—A Rapid Method for Washing Gold Beads. E. J. Hall. (Eng. and Min. Journ., July 24, 1915; 1 p., illus.) 20c.

1542—CALIFORNIA—Seneca Mining District, California. W. H. Wright. (Eng. and Min. Journ., June 19, 1915; 2 pp., illus.) 20c.

1543—CANADA—Beaver Lake District, Saskatchewan. Charles A. Banks. (Min. and Sci. Press, June 19, 1915; 1 p., illus.) 20c.

1544—CENTRAL AMERICA—New York & Honduras Rosario Mining Co. J. M. De Hart. (Min. and Eng. Wld., June 19, 1915; 2¾ pp., illus.) 20c.

1545—CENTRAL STATES—Silver, Copper, Lead and Zinc in the Central States in 1914. B. S. Butler and J. P. Dunlop. (Mineral Resources of the U. S., 1914, Part II; 98 pp.)

1546—COST of an Ounce of Gold. Percy E. Barbour. (Eng. and Min. Journ., July 10, 1915; 1½ pp.) An interesting compilation showing the cost of production at various important mines. 20c.

1547—GOLDFIELD Re-visited. T. A. Rickard. (Min. and Sci. Press, June 12, 1915; 2¾ pp., illus.) Continuation of article previously indexed. 20c.

1548—MILLING Below Sea Level at McCausland Mine, Death Valley, Calif. Lewis H. Eddy. (Eng. and Min. Journ., July 10, 1915; 1¼ pp., illus.) 20c.

1549—NEVADA—Mining in the Shale at Goldfield. J. K. Turner. (Min and Sci. Press, June 26, 1915; 1¼ pp., illus.) 20c.

1550—ONTARIO—The Mining Industry in that Part of Northern Ontario Served by the Temiskaming & Northern Ontario Ry. during 1914. Arthur A. Cole. (Temiskaming & No. Ont. Ry. Com., 1914; 74 pp., illus.)

1551—RAND—Ore Reserves of the Rand. A. Cooper Key. (Eng. and Min. Journ., July 24, 1915; ¾ p.) 20c.

1552—SONORA—Conditions in Sonora. (Min. and Sci. Press, July 17, 1915; 1½ pp., illus.) 20c.

1553—SOUTH AMERICA—Mineral Industry of South America with Special Reference to Bolivia. George W. Schneider. (Min. Sci., June, 1915; 10 pp., illus.) 20c.

1554—UTAH—New Gold Camp of Goldstrike in Washington County. Will C. Higgins. (Salt Lake Min. Rev., May 15, 1915; 5¼ pp., illus.) 20c.

1555—WESTERN AUSTRALIA—Notes on the Geology and Mining at Sandstone and Hancock's, East Murchison Goldfield. E. de C. Clarke. (Bull. 62, West. Aust. Geol. Surv., 1914; 66 pp., illus.)

IRON ORE DEPOSITS, MINING, ETC.

1556—CHROMIC IRON ORE—The Production of Chromic Iron Ore in 1914. J. S. Diller. (Mineral Resources of the U. S., 1914, Pt. I; 15 pp., illus.)

1557—CUBA—Additional Data on Origin of Lateritic Iron Ores of Eastern Cuba. C. K. Leith and W. J. Mead. (Bull. A. I. M. E., July, 1915; 4 pp., illus.) 40c.

1558—MECHANICAL FEATURES at a Lake Superior Iron Mine. P. B. McDonald. (Min. and Sci. Press, July 10, 1915; 1⅔ pp., illus.) 20c.

1559—MESABI RANGE—Orebodies of the Mesabi Range—I and II. J. F. Wolff. (Eng. and Min. Journ., July 17 and 24, 1915; 10½ pp., illus.) 40c.

1560—MINNESOTA—Structure of the Cuyuna Iron-Ore District of Minnesota. Charles A. Cheney, Jr. (Eng. and Min. Journ., June 26, 1915; 2¾ pp., illus.) 20c.

1561—NEW JERSEY—Development of Nation's Oldest Iron Mine (Mt. Hope, N. J.). H. M. Roche and J. C. Stoddard. (Iron Tr. Rev., July 22, 1915; 6 pp., illus.) 20c.

1562—ORE DEPOSITS—The Formation and Distribution of Bog Iron-Ore Deposits. C. L. Lake. (Bull. A. I. M. E., July, 1915; 8 pp.) 40c.

1563—TENNESSEE—The Iron Ore Deposits of Lewis County, Tennessee. Reese F. Rogers. (Resources of Tenn., Vol. V, No. 3, July, 1915; 62 pp., illus.)

IRON AND STEEL—METALLURGY

1564—ACCIDENT PREVENTION by the Steel Corporation. A. A. Willoughby. (Min. and Sci. Press, July 17, 1915; 1 p.) 20c.

1565—BLAST-FURNACE PLANT AUXILIARIES and General Arrangement. J. E. Johnson, Jr. (Met. and Chem. Eng., July, 1915; 10¼ pp., illus.) Continuation of article previously indexed. 40c.

1566—BLOWING ENGINES—Gas Blowing Engines of New Design at Steelton Plant, Pennsylvania Steel Co. (Iron Tr. Rev., July 1, 1915; 3 pp., illus.)

1567—BY-PRODUCTS—De la Récupération des Sous-Produits du Gaz de Gazogene dans l'Industrie Metallurgique. Otto Wolff. (Rev. de Met., Mar., 1915; 8 pp., illus.) From "Stahl u. Eisen."

1568—CUPOLA OPERATION—Scientific Operation of a Cupola. David Townsend. (Iron Tr. Rev., July 15, 1915; 3 pp., illus.) Paper before Philadelphia Foundrymen's Assn. 20c.

1569—ELECTRIC FURNACE in the Foundry. W. L. Morrison. (Iron Tr. Rev., July 22, 1915; 3 pp., illus.) From paper before Am. Foundrymen's Assn. 20c.

1570—FUEL SAVING—Furnace Curves for Plotting Fuel Consumption. R. J. Weitlaner. (Met. and Chem. Eng., July, 1915; 3½ pp., illus.) 40c.

1571—GALVANIZING STANDARDS—Details of a New Method to Determine the Amount of Spelter Coating on Sheets and Wire. J. A. Aupperle. (Iron Tr. Rev., June 24, 1915; 1 p.) Paper before Am. Soc. for Testing Materials. 20c.

1572—HARDENING TOOL STEEL—Factors in Hardening Tool Steel. John A. Mathews and Howard J. Stagg, Jr. (Iron Tr. Rev., July 22, 1915; 3½ pp.) Paper before Am. Soc. Mechan. Engrs. 20c.

1573—MIXER—The Metal Mixer. F. C. Thompson. (Iron and Coal Tr. Rev., July 9, 1915; 2½ pp., illus.) 40c.

1574—PROPERTIES—Some Suggestions Regarding the Determination of the Properties of Steel. A. N. Mitinsky. (Advance copy, A. I. M. E., Sept., 1915; 9 pp., illus.) 40c.

1575—ROLLING MILLS—Etudes sur les Laminoirs Americains. J. Puppe. (Rev. de Met., Mar., 1915; 17½ pp., illus.) From "Stahl u. Eisen."

1576—SLAG—Making Money from Furnace Slag. (Iron Tr. Rev., June 24, 1915; 1½ pp., illus.) Description of a new method of handling and marketing blast-furnace slag, using twin beds and a patented chain system. 20c.

1577—SOUND STEEL for Rails and Structural Purposes. Robert A. Hadfield. (Journ. Frank. Inst., June, 1915; 18 pp., illus.) 60c.

1578—SPECIAL STEELS—A Comparison of the Properties of a Nickel, Carbon and Manganese Steel Before and After Heat Treatment. Robert R. Abbott. (Advance copy, A. S. M. E., June, 1915; 9 pp., illus.)

LEAD AND ZINC

1579—CENTRAL STATES—Silver, Copper, Lead and Zinc in the Central States in 1914. B. S. Butler and J. P. Dunlop. (Mineral Resources of the U. S., 1914, Part II, 98 pp.)

1580—ELECTROMETALLURGY—Neuerungen in der Elektrometallurgie des Zinks. Franz Peters. (Gluckauf, June 12 and 19, 1915; 15½ pp., illus.) 80c.

1581—ZINC CORPORATION and the War. (Eng. and Min. Journ., July 17, 1915; 2½ pp.) Address by Chairman F. A. Gorett at recent annual meeting of the Zinc Corporation, setting forth the effects of the war on the Australian companies who have had zinc concentrates smelted in Europe. 20c.

1582—ZINC WASTE—The Refining of Zinc Waste. L. J. Krom. (Metal Ind., July, 1915; 2 pp., illus.) 20c.

OTHER METALS

1583—ANTIMONY and the War. (Engineering, July 9, 1915; 1¾ pp.) 40c.

1584—QUICKSILVER—Wet Method of Mercury Extraction. E. Bryant Thornill. (Min. and Sci. Press, June 5, 1915; 1¾ pp.) 20c.

1585—RADIOACTIVITY. Editorial. (Engineering, May 28, 1915; 1¾ pp., illus.) 40c.

1586—RADIUM—Some Experiments on the Quantitative Determination of Radium. Herman Schlundt. (Radium, July, 1915; 5½ pp., illus.) From Trans. Am. Electrochem. Soc., Vol. XXVI. 40c.

1587—SECONDARY METALS—The Recovery of Secondary Metals in 1914. J. P. Dunlop. (Mineral Resources of the U. S., 1914, Pt. I; 9 pp.)

1588—TELLURIUM—Some Rare Metals—Tellurium. (Brass Wld., June, 1915; 3¼ pp.) 20c.

1589—TIN—The Physical Condition of Cassiterite in Cornish Mill Products. J. J. Beringer. (Bull. 129, I. M. M., June 17, 1915; 29½ pp.) Discussion on paper previously indexed.

1590—VANADIUM—The Milling of Vanadium Ore. A. F. Hallett. (Colo. Sch. of Mines Mag., July, 1915; 2½ pp., illus.) 40c.

NONMETALLIC MINERALS

1591—ASBESTOS—The Production of Asbestos in 1914. J. S. Diller. (Mineral Resources of the U. S., 1914, Part II; 10 pp., illus.)

1592—BARYTES at Kings Creek, S. C., Joel H. Watkins. (Eng. and Min. Journ., June 19, 1915; ¾ p., illus.) 20c.

1593—BAUXITE—La Bauxite le Monde. F. Laur (Metaux et Alliages, Apr. 15-30, 1915; 1 p.). Continuation of article previously indexed. 40c.

1594—CALIFORNIA—Non-Metallic Products. Samuel H. Dolbear. (Min. and Sci. Press, July 10, 1915; 2 pp.) Notes on kaolin, borax, magnesite and manganese. 20c.

1595—CHROME—Les Mines de Chrome en Turquie. (Metaux et Alliages, Apr. 15-30, 1¼ pp.)

1596—CORUNDUM MINING in Ontario. A. E. Barlow. (Can. Min. Journ., June 15, 1915; 3½ pp.) From Memoir 57 of Can. Geological Survey. 20c.

1597—DIAMOND FIELDS of German South-West Africa. Charles W. Boise. (Min. Mag., June, 1915; 12 pp., illus.) 60c.

1598—KAOLIN—Wilson W. Hughes. (Min. and Sci. Press, June 19, 1915; 3½ pp., illus.) 20c.

1599—MICA—The Production of Mica in 1914. Douglas B. Sterrett. (Mineral Resources of the U. S., 1914, Pt. II; U. S. Geol. Surv., 1915; 11 pp.)

1600—MINERAL PAINTS—The Production of Mineral Paints in 1914. James M. Hill. (Mineral Resources of the U. S., 1914; Part II; 20 pp.)

1601—NITRATE PRODUCTION by Modern Methods. (Min. and Eng. Wld., July 24, 1915; 1 p., illus.) 20c.

1602—PHOSPHATE ROCK—The Production of Phosphate Rock in 1914. W. C. Phalen. (Mineral Resources of the U. S., 1914; 18 pp.)

1603—POTASH—Drilling Costs in Potash Prospecting. E. E. Free. (Eng. and Min. Journ., July 17, 1915; 1¼ pp.) 20c.

1604—PYRITES—New Sampling Plant at Hamburg, Germany. (Eng. and Min. Journ., July 24, 1915; 1½ pp., illus.) Describes plant erected primarily for sampling pyrites.

1605—SLATE—The Production of Slate in 1914. A. T. Coons. (Mineral Resources of the U. S., 1914, Part II; 14 pp.)

1606—SULPHUR—Sui Metodi d'Analisi degli Zolfi. M. G. Levi. (Rassegna Mineraria, June 16, 1915; 5½ pp.) 40c.

PETROLEUM AND NATURAL GAS

1607—BITUMINOUS SCHIST—Per L' Industria degli Scisti Bituminosi in Italia. Guido Pulle. (L'Ind. Chim., Min. and Met., May 25, 1915; 6¾ pp.)

1608—BORING AND DRILLING on Oilfields. Paul Dvorkovitz. (Petrol. Rev., June 12 and 19, 1915; 3¾ pp.) 80c.

1609—DRILLING—Suggestions for Oil-Drilling in Russia. M. J. Deen. (Petrol. Rev., June 26, 1915; 3 pp., illus.) 40c.

1610—MEXICO—The Occurrences of Petroleum in Eastern Mexico as Contrasted with Those in Texas and Louisiana. E. T. Dumble. (Advance copy, A. I. M. E., Sept., 1915; 16 pp.) 40c.

1611—PERU—Ensayo Sobre la Genesis Probarle de los Petroleos y Asfaltos del Peru. Enrique I. Duenas. (Bol. de Minas, Mar. 31, 1915; 6¾ pp., illus.)

1612—REFINING—Gulf Refining Co. to Test New Oil Extraction Process (McAfee). Almer McDuffie McAfee. (Oil, Paint and Drug Rep., 1915; 1½ pp., illus.)

1613—WASHINGTON—The Possible Occurrence of Oil and Gas Fields in Washington. Charles E. Weaver. (Bull. A. I. M. E., July, 1915; 8½ pp.) 40c.

1614—WILD GAS WELLS—The Control of Wild Gas Wells. Rockwell H. Johnson and L. G. Huntley. (Petrol. Rev., June 5, 1915; 1½ pp., illus.) 40c.

1615—WYOMING—The Little Buffalo Basin Oil and Gas Field, Park and Hot Springs Counties, Wyoming. P. F. Hintze, Jr. (Bull. 11, Wyoming State Geologist's Office, 1915; 25 pp., illus.)

ECONOMIC GEOLOGY—GENERAL

1616—ARIZONA—Ground Water in Paradise Valley, Arizona. O. E. Meinzer and A. J. Ellis. (Water-Supply Paper 375-B, U. S. Geol. Surv., 1915; 27 pp., illus.)

1617—BRAZIL—The Geology of Central Minas Geraes, Brazil. E. C. Harder and R. T. Chamberlin. (Journ. of Geol., May-June, 1915; 38 pp., illus.) 60c.

1618—CALIFORNIA—Eruptions of Mt. Lassen and Tertiary Eruptions of the Sierra Nevada. H. W. Turner. (Min. and Sci. Press, June 19, 1915; 1¾ pp., illus.) 20c.

1619—ORE DEPOSITION—Persistence of Ore in Depth. T. A. Rickard. (Bull. 129, I. M. M., June 17, 1915; 9 pp.) Further contributed remarks on paper previously indexed.

1620—ORE DEPOSITS—Zur Anwendung metallographischer Methoden auf die mikroskopische Untersuchung von Erzlagerstätten. B. Granigg. (Metall u. Erz, May 22, 1915; 12 pp., illus.) 40c.

1621—SIBERIA—The Altai Region, Siberia. H. W. Turner. (Min. and Sci. Press, June 26, 1915; 8¼ pp., illus.) 20c.

MINING—GENERAL

1622—ACCIDENTS—Monthly Statement of Coal-Mine Fatalities in the United States, April, 1915. Albert H. Fay. (U. S. Bureau of Mines, Apr., 1915; 12 pp.)

1623—AERIAL WIRE ROPEWAYS. J. Walwyn White. (Iron and Coal Tr. Rev., July 9, 1915; 1½ pp.) Abstract of paper before Birmingham Assn. of Mechan. Engr. 40c.

1624—ARIZONA—Mining in Arizona. Charles F. Willis. (Min. and Sci. Press, July 17, 1915; 1½ pp.) 20c.

1625—BLACKSMITH SHOP—Inefficiencies in the Mine Blacksmith Shop. Letson Balliet. (Min. and Eng. Wld., July 24, 1915; 1 p.) 20c.

1626—CHILE—Monografia Sobre el Estado Actual de la Mineria en la Provincia de Coquimbo i Descripcion de Sus Yacimientos Minerales mas Importantes. (Bol. Soc. Nac. de Mineria, Feb., 1915; 5 pp.)

1627—CHINA—Mining Conditions in China. F. Lynwood Garrison. (Eng. and Min. Journ., July 3, 1915; 2½ pp.) 20c.

1628—COSTS—Operating Costs at a Small Mexican Mine. Roy Hutchins Allen. (Eng. and Min. Journ., June 26, 1915; 2¼ pp.) 20c.

1629—DRAINAGE—Bendigo Mines' Drainage Scheme. W. H. Cundy. (Min. and Eng. Rev., 2 pp.) 40c.

1630—DRILLING CAMPAIGN of the Consolidated Coppermines Co. (Eng. and Min. Journ., June 19, 1915; 1¾ pp., illus.) 20c.

1631—DUST—Notes on the Dust-Allaying Plant at the Ferreira Deep Dump. S. Newton. (Journ. Chem., Met. and Min. Soc. of So. Afr., Apr., 1915; ¾ p.) Author's reply to discussion of paper previously indexed. 60c.

1632—EXPLOSIONS—Methods of Preventing and Limiting Explosions in Coal Mines. George S. Rice and L. M. Jones. (Tech. Paper 84, U. S. Bureau of Mines, 1915; 45 pp., illus.) 20c.

1633—EXPLOSIVES—Safety Measures in the Use of Explosives. Wm. Cullen. (Journ. Chem., Met. and Min. Soc. of So. Afr., Apr., 1915; 5 pp., illus.) Discussion of paper previously indexed. 60c.

1634—FILLING—Settling Tanks for Hydraulic-Packing Plant. (Coll. Guard., May 21, 1915; ⅔ p., illus.) From an article by E. Steuer in "Glückauf." 40c.

1635—HOISTING—The Prevention of Overwinding and Overspeeding in Shafts. G. G. T. Poole. (Trans. N. Eng. Inst. Min. and Mech. Engrs., June, 1915; 26 pp., illus.)

1636—HUNGARY—Ungarns Montanindustrie und Aussenhandel in den wichtigsten Montanprodukten im Jahre 1913. M. Przyborski. (Montanistische Rundschau, July 1, 1915; 4 pp.) 40c.

1637—MINE TOOL STEEL Used Over Again. Geo. E. Edwards. (Min. and Eng. Wld., July 24, 1915; 1 p.) 20c.

1638—MINING METHOD—The Five-Hole Cut. B. F. T. (Eng. and Min. Journ., June 19, 1915; ¾ p.)

1639—MINING ORE FROM A CAVED STOPE at Mina Santa Francisca, Mexico. James E. Harding. (Eng. and Min. Journ., July 10, 1915; 1½ pp., illus.)

1640—NEW MEXICO—The Mineral Resources of New Mexico. Fayette A. Jones. (Bull. 1, N. M. State School of Mines, 1915; 77 pp., illus.)

1641—SAFETY as Practiced in the State of Montana. (Min. and Eng. Wld., June 26, 1915; 1¼ pp.) A statement by the State Industrial Accident Board. 20c.

1642—SAFETY RULES—California Safety Rules. W. R. Percy. (Eng. and Min. Journ., June 26, 1915; ¾ p.) Comments on the draft of safety rules, previously published. 20c.

1643—SURVEYING, ETC.—Engineering Notes and Methods at Miami. H. P. Bowen. (Eng. and Min. Journ., July 3, 1915; 2¾ pp., illus.) Kinks about underground surveying, methods of taking and keeping notes, filing and recording them on maps and assay plans, etc. 20c.

1644—TIMBERING STOPES for Safety. H. H. Hodgkinson. (Eng. and Min. Journ., July 10, 1915; 1 p., illus.) 20c.

1645—TRANSPORTATION OF SUPPLIES—Handling Mine Supplies by Cableway at Nome, Alaska. S. R. Stone. (Min. and Eng. Wld., July 10, 1915; 2 pp., illus.) 20c.

1646—TRANSPORTING WOOD—Cheap Method of Transporting Cordwood and Timbers at Oriental Cons. Mines. J. D. Hubbard. (Eng. and Min. Journ., July 24, 1915; ¾ p., illus.) 20c.

1647—UTAH—Mining in Utah. L. O. Howard. (Min. and Sci. Press, July 3, 1915; 2 pp.) 20c.

1648—VENTILATION—Note on a Method of Ventilating Sinking Shafts, Winzes and Drives. S. Nettleton. (Journ. Chem., Met. and Min. Soc. of So. Afr., Mar., 1915; 1¼ pp.) Discussion on paper previously indexed. 60c.

ORE DRESSING—GENERAL

1649—AUSTRALIA—Broken Hill Milling Practice. (Min. and Eng. Rev., May 5, 1915; 6 pp., illus.) 40c.

1650—CLASSIFIERS—Notes on Hydraulic Classifiers and Classifications. P. Graham Martyn. (Journ. Chem., Met. and Min. Soc. of So. Afr., Apr., 1915; 1⅓ pp.) 60c.

1651—CRUSHING—Degree of Crushing to Free the Economic Minerals. D. P. Hynes. (Min. and Sci. Press, June 26, 1915; 1 p.) 20c.

1652—CRUSHING—Grinding and Crushing Machinery. M. A. Crosbie. (Journ. Soc. Chem. Ind., Apr. 15, 1915; 6½ pp., illus.)

1653—CRUSHING—Hardinge Mill Data. Arthur F. Taggart. (Bull. A. I. M. E., July, 1915; 11½ pp.) 40c.

1654—FLOTATION in Australia. Charles S. Galbraith. (Min. and Sci. Press, July 17, 1915; 3½ pp., illus.) 20c.

1655—FLOTATION—Preferential Flotation. O. C. Ralston. (Min. and Sci. Press, June 26, 1915; 5 pp.) Largely a compilation of patent literature. 20c.

1656—GRIZZLIES—Quincy Dump and Grizzlies. L. Hall Goodwin. (Eng. and Min. Journ., July 17, 1915; ½ p., illus.) 20c.

METALLURGY—GENERAL

1657—ALLOYS—L'Influence de la Coalescence sur les Propriétés Mécaniques des Alliages. A. Portevin and V. Bernard. (Rev. de Met., Mar., 1915, 7 pp., illus.)

1658—FLOW OF SOLUTION—The V-Notch Weir. John E. Rothwell. (Eng. and Min. Journ., July 24, 1915; 1½ pp., illus.) 20c.

1659—HARDENING of Metals. General discussion by R. A. Hadfield, G. T. Beilby, Ernst Cohen, J. C. W. Humfrey, and others. (Trans. Faraday Soc., May, 1915; 87 pp., illus.)

1660—INSULATION—The Thermal Insulation of High-Temperature Equipment. P. A. Boeck. (Advance copy, A. I. M. E., Sept., 1915; 12 pp., illus.) 40c

1661—PULP—Solution of Pulp Problems by Graphic Methods. W. J. McCauley. (Eng. and Min. Journ., July 17, 1915; 3 pp., illus.) 20c.

1662—RADIOGRAPHY of Metals. Wheeler P. Davey. (Advance copy, A. I. M. E., Sept., 1915; 11 pp., illus.)

1663—RADIOGRAPHY of Metals. Wheeler P. Davey. (Gen. Elec. Rev., Aug., 1915; 5½ pp., illus.) Later investigations on the examination of metals by X-rays, and their results. 40c.

1664—REFRACTORIES—The Thermal Conductivity of Refractory Materials. G. Dougill, H. J. Hodsman and C. W. Cobb. (Journ. Soc. Chem. Ind., May 15, 1915; 6 pp.)

1665—ROASTERS—Improvements for Ropp Roasters. Edgar Hall. (Eng. and Min. Journ., July 24, 1915; 1¼ pp., illus.) 20c.

1666—SILUNDUM—The Preparation, Properties and Composition of Silundum. Samuel A. Tucker and Alexander Lowy. (Journ. Ind. and Eng. Chem., July, 1915; 6½ pp., illus.) 60c.

1667—SMOKE—The Theoretical and Experimental Consideration of Electrical Precipitation. A. F. Nesbit. (Proc. A. I. E. E., Feb., 1915; 14½ pp., illus.)

1668—WELDING—Les Impuretés Dangereuses des Métaux d'Apport pour la Soudure Autogène. R. Amédée. (Metaux et Alliages, Apr. 15-30, 1915; 2¼ pp.)

FUELS

(See also "Petroleum and Natural Gas")

1669—COKE—Modern Appliances in Coke Manufacture. E. C. Ricks. (Coal Age, July 3, 1915; 3 pp., illus.) 20c.

1670—COKE—Modern Coke-Handling Methods. F. V. Hetzel. (Coal Age, July 3, 1915; 2 pp., illus.) 20c.

1671—COKING of Coal at Low Temperatures with Special Reference to the Properties and Composition of the Products. S. W. Parr and H. L. Olin. (Bull. Univ. of Ill., May 31, 1915; 39 pp., illus.)

1672—FUEL BRIQUETTING in 1914. Edward W. Parker. (Mineral Resources of the U. S., 1914, Part II; 5 pp.)

The Engineering and Mining Journal

VOLUME 100 AUGUST 14, 1915 NUMBER 7

Amador Consolidated Milling Plant, Amador City, Calif.

By T. S. O'Brien*

SYNOPSIS—A plant operating on Mother Lode ores and following a practice unusual in that district. No amalgamation is done in mortars, and it is planned to eliminate the practice of stamp crushing. An unusual zinc-precipitation system is used similar to that of the Ajax, Victor, Colo.

Milling was resumed at the Amador Consolidated plant on May 1, 1915, after a shutdown of 60 days, during which time the plant was entirely overhauled, and to the original twenty 1000-lb. stamps were added two 8-ft. by 36-in. Hardinge mills, 10 new double- and 1 single-deck Deister Concentrator Co. tables and a 32-ft. diameter by 16-ft. deep thickening tank. The new mill will have a capacity of 300 tons daily, compared with 90 tons daily in the old mill.

The design of this mill is a departure from the usual Mother Lode practice, inasmuch as no amalgamating is done in the mortar, and the ore—consisting mostly of hard quartz with a little slate, carrying about 1½% pyrite as it comes from the bins—is fed into revolving screens having ⅜-in. openings. Only the oversize of these screens goes to the stamps, while the undersize, amounting to about 25%, is passed around and joins the discharge from the stamps going to the drag classifiers, the sands discharge of which is fed to the Hardinge mills. The excess water and slimes overflow goes to the thickening tank. The ton-cap screens on the battery vary from ⅜- to ¾-in. opening, depending on the hardness of the ore going through, the object being to regulate the feed, percentage of water and pebble load in the Hardinge mills so the discharge from them will show a maximum of minus 30-mesh sands and a minimum of slimes. Even now it is indicated that there will be less slimes than with the stamps crushing to 20 mesh.

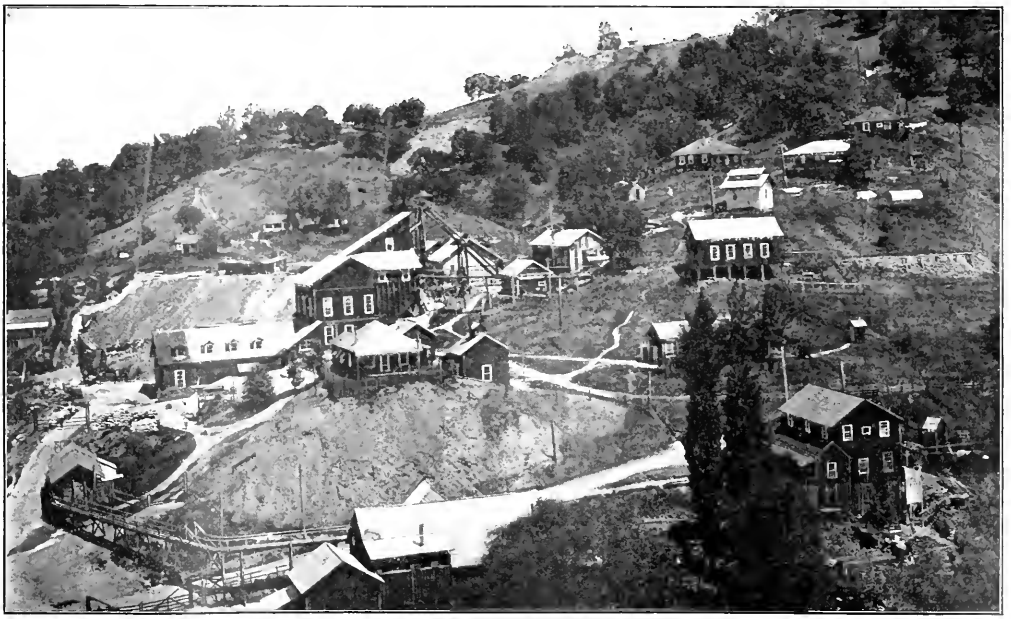

FIG. 1. GENERAL VIEW OF THE AMADOR CONSOLIDATED PLANT

*Superintendent, Amador Consolidated Mines Co., Amador City, Calif.

The discharge from the Hardinge mills goes into the Hardinge amalgamators, which are attached to and revolve with the mill. Mercury is fed into this amalgamator as required by the condition of the outside plates, in the same manner as feeding it into the stamp mortar. About a dozen small copper balls, made from ¼- or ⅜-in. wire, are kept in the amalgamator. As these balls roll around they build up, forming good-sized amalgam balls which are removed daily while the mill is in operation; after removing the accumulated amalgam, the balls are returned to repeat the operation.

The discharge from the amalgamator passes over the usual copper plates and goes to a hydraulic classifying launder having a trap and three spigots, one each for coarse, medium and fine sands, which go to separate tables. The slimes-overflow from the hydraulic classifiers joins the slimes-overflow from the drag classifier, going to a sump from which it is pumped to the thickening tank. From this tank the thickened slime is fed to the slimes tables and the clear overflow from the thickening tank is returned and again used for general mill purposes.

Treatment of Concentrates

The concentrates—having a specific gravity of about 4.4—from all the tables are piped to a central sump from which they are elevated to the second set of amalgamating plates where any gold or amalgam that escapes the first set of plates, or was carried over in the slimes-overflow, is recovered. From the second set of amalgamating plates the concentrates are piped and run by gravity to the dewatering bins from which they are trammed to the cyanide plant, which has a capacity of about 300 tons per month, where they are ground to pass a —200-mesh screen in a 4½-ft. by 12-in. Hardinge mill operated in closed circuit with a drag classifier. To this mill is also attached a Hardinge amalgamator which discharges on to a small copper plate. About 5% of the gold released during grinding is recovered previous to cyanide treatment.

The overflow from the classifier is pumped to one 18-ft. diameter by 12-ft. deep treatment tank equipped with the Trent cyaniding apparatus. This tank, with a dilution of 70%, has a capacity of 30 tons of concentrates. When starting to grind a charge, the treatment tank is filled with barren solution and the circulating pump started while the valves are set to operate as a thickener and replacer. Then the pulp from the classifier, having about 80% dilution and having had about 50% of the values dissolved during grinding, is pumped into a 12x12-in. box hung in the center and submerged 3 ft. While the charge is being ground and thickened in the bottom of the treatment tank, the clear overflow, with a large percentage of the dissolved values, goes to the sump tank, which has a filter bottom. After the charge is ground and previous to agitation, about 50% of the solution in the treatment tank is replaced with barren solution and the valves on the treatment tank changed to operate as an agitator. This process is continued for 6 or 8 hr. after which all the recoverable values are in solution. The valves are again changed on the treatment tank so as to operate it as a thickener and replacer and about 10% in excess of the solution in the treatment tank is replaced with barren solution. Then 20 tons of wash water carrying about 2 lb. alkalinity per ton, is added and the charge allowed to settle into the wash water. The solution above the pulp is then decanted off into the sump tank, and the pulp sluiced to waste.

Cyanide-Treatment Machinery

The treatment tank is equipped with test cocks placed vertically about 1 ft. apart, from which samples can be taken for assay or titration during treatment or while

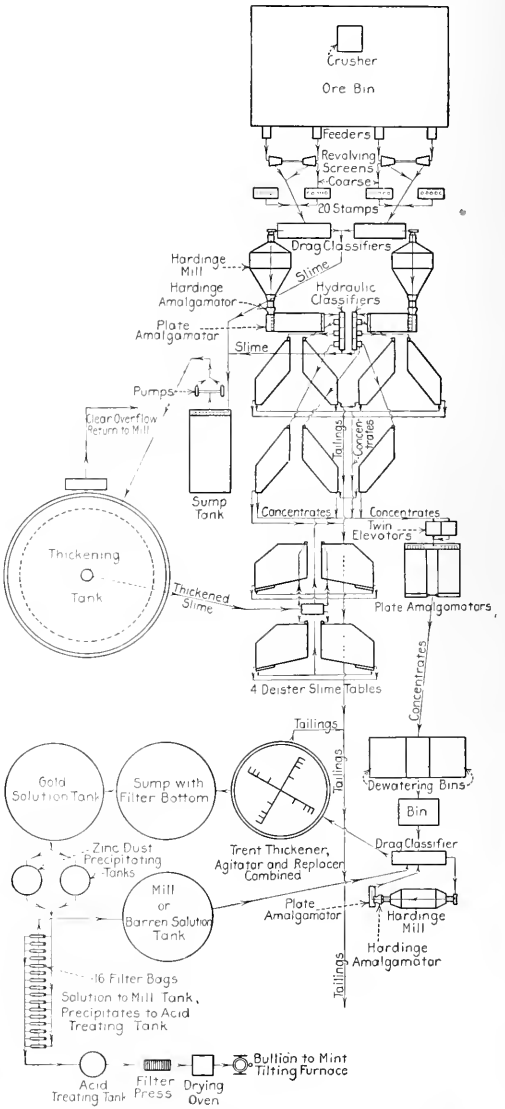

FIG. 2. FLOW SHEET, AMADOR CONSOLIDATED MILL

replacing. To illustrate the agitating ability of this machinery, it is on record that one charge, on account of some trouble with precipitation, was allowed to settle and held in the tank 80 hr. and in 15 min. after the

circulating pump was started the arms were making a complete revolution. Two hours after starting the samples taken from all the test cocks showed about the same specific gravity, showing that the entire charge was in suspension.

Precipitation was begun with zinc shavings, but owing to erratic precipitation and to the amount of labor required for dressing the boxes, the use of shavings was discarded and zinc dust installed. The method now used is the same as at the Ajax property, of Victor, Colo. The method makes use of two 5-ton tanks equipped with mechanical agitators, into which the solution from the gold tank is run. When the tank is about two-thirds full, the required amount of lead acetate and zinc dust is added, and by the time the tank is full, it has had sufficient agitation and is then pumped to the filters. While one tank is being pumped out, the other is being filled and agitated. Both the solution inlet pipe and pipe to the pump are equipped with three-way valves, making the flow to the filters almost continuous. This system is more satisfactory and economical from every standpoint than zinc shavings.

Filtering the precipitates is done with canvas bags each inclosing an inner bag of fine muslin. These are hung on a manifold, each bag having separate connection and valve to the main header, and the solution from the bags drains into a launder leading to the mill-solution tank.

The idea of these filter bags was furnished by H. R. Conklin of the Lluva de Oro Co., Chihuahua, Mexico.[1] They are practically the same as he used except that his bags tapered, and as the precipitates collected in the bottom or large end, it was necessary to destroy the bags to remove the precipitates. To overcome this, a cast head 4 in. in diameter was made to screw on to the 1-in. nipples of the manifold and the bags made straight, being thus 4½ in. in diameter by 36 in. long. These bags are fastened to the cast head with heavy twine and they can be readily removed from the manifold and used over a great many times. The inner bag, which contains the precipitates, can be easily removed from the outer bag and washed out into the clean-up tank, where the precipitates are acid-treated previous to smelting.

Neither the mill nor the cyanide plant has been in operation long enough to get any detailed data on costs, but the estimate on the mill, treating 9000 tons a month, is put at a total cost of 30c. per ton and—judging from the work done in the old mill, which made a 90% extraction—it is expected that a further saving will be made. During the next year the stamps will be discarded and ball mills or some other crushing machinery installed to give a ⅜-in. product to the Hardinge pebble mills. With about a million and a half tons of available ore blocked out in the mine above the 700-ft. level, the policy of the company will be to increase the mill capacity up to 1000 tons or more daily as soon as possible. On the 200 tons of concentrates treated at the cyanide plant, an extraction of 90.1% was made and by further modifications it is expected to increase this to 95%, a figure which was reached in the small experimental plant. On a basis of 300 tons per month the total treatment cost will be about $5 per ton.

[1]First described in "Eng. and Min. Journ.," May 17, 1913.

Bagley Scraper for Gravel Mining in Alaska

By Lewis H. Eddy*

The Bagley scraper was successfully used by Riley & Marsten on Otter Creek, Iditarod district, Alaska, in handling the gravel of two 20-acre claims during the season of 1914. About 10 acres remain to be scraped this season. That portion of the Riley & Marsten claims occupying the stream is worked with a 3½-cu.ft., Union Construction Co.'s bucket-elevator, flume-type dredge driven by a distillate engine.

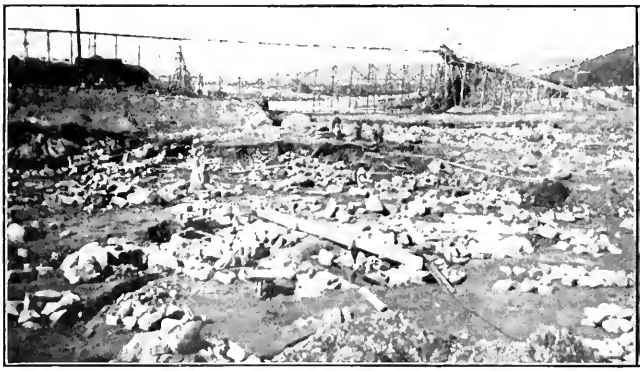

FIG. 1. CLEANED BEDROCK WITH THE SET-UP IN THE BACKGROUND

FIG. 2. SCRAPING UP A LOAD

The dredge operates in the stream while the scraper is used only on unwatered ground. The stream and bed naturally cover a considerable area, so that preparatory to scraping operations, the water is forced back and off the ground by a system of ditches. In other words, the ground is unwatered.

With from 2 to 6 ft. overburden and 4 to 5 ft. of waste gravel there is a total depth from surface to bedrock of from 8 to 12 ft. Thus a large amount of material must be removed before the gold is reached. The method employed is to ground-sluice the overburden, scrape the waste to one side, cut to bedrock with the

*Associate editor, "Engineering and Mining Journal, San Francisco, Calif.

scraper and load the material into cars which are hauled up an inclined track and their contents dumped into a dump-box at the head of the sluices.

The cost of handling the gravel by this method is approximately 20c. per sq.ft. of soft ground and 40c. per sq.ft. of hard ground. The yield Mr. Riley places at 75c. to $1 per sq.ft.

The scraper used at Otter Creek handles about 3 cu.yd. per load. It is manufactured by the Bagley Grader Co., of Tacoma, Wash., in various sizes from 1 to 5 cu.yd. capacity. It is so constructed with back curvature that no bottom is provided. It works with either side down. The knives which cut or peel up the dirt are fitted at the edges of the back. The edge of the scraper may be provided

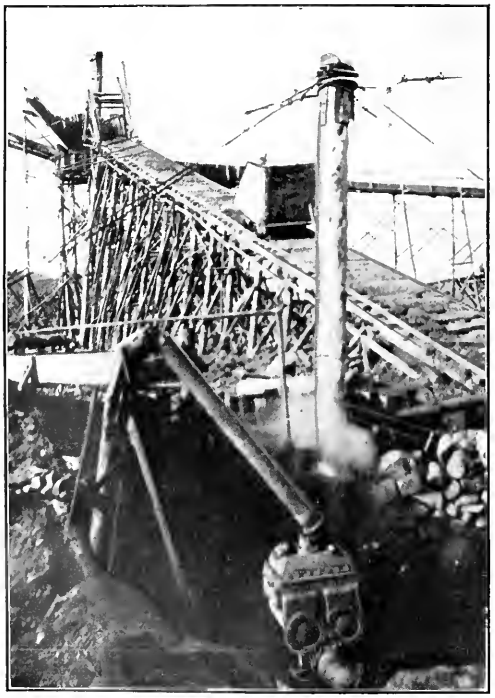

FIG. 3. INCLINED TRACK, LOADED CAR, LEAD MAST AND SEEPAGE PUMP

with teeth about 3 in. in section and set about 1 ft. apart. The scraper is automatically filled, lifting the back slightly so that the loaded scraper slides off on top of the ground. Unloading is accomplished by hauling the scraper back, leaving the load where it stopped, or by dumping it into a car. When the scraper goes ahead, the weight is on the scraping edge and when it goes back, the weight drags on the side.

The method of operation is practically the same in all classes of scraping. The practice on Otter Creek is to lay out the ground in an area about 500 ft. long and 400 ft. wide, so as to work about 200,000 sq.ft. of bedrock in one cut. After scraping to bedrock, the cleaning of the floor and services is done by hand.

The accompanying photographs give a fair idea of the situation and operation of the plant. Fig. 3 shows the inclined track, and a loaded car traveling up to the dump-box. The mast illustrated is the main lead mast. The seepage pump, which keeps the cut dry, appears in the middle foreground of the picture. In the background is the flume, carrying gravity water to the dump-box. A general view of the plant in the back-ground is given in Fig. 1 with the cleaned bedrock in the foreground. The rocks and gravel scattered about have been left in order to save the unnecessary expense of moving them, except from one part of the ground to the other when necessary to clean any particular part of the bedrock. This illustration shows the condition of the bedrock after having been finished by hand.

The set-up is placed at the outer edge of the cut or area to be scraped, opposite the river. The inclined track extends upward toward the cut and the dump- and sluice-boxes are placed at the head of the track. Two masts are situated on either side of the track about 60 ft. apart. One stands just within the cut and the other just outside. A cable extends from one mast to the other. The lead-line of the scraper is attached to this cable by a block which runs from mast to mast, so the lead may be changed to operate the scraper from any point of the area being scraped. Each mast is guyed with three lines.

The engine is set so that the engineer can see the work, usually on the opposite side from the set-up. Steam power and wood fuel are used.

The car is built high at the back, the sides running to a point at the forward end of the bottom. It is 10 ft. long, 5 ft. wide and 5 ft. high at the rear end, and is so pivoted as to avoid spilling the soft mud or water. The dump-box is 40 ft. long, 5 ft. wide and 3 ft. deep. This box narrows in the last 10 ft. to a width of 18 in. where it is connected to an 18-in. flume that is 125 ft. long and 3 ft. deep. The dump-box is lined on both sides with 2-in. plank. The bottom of it is provided with poles about 5 in. in diameter and a little short of 10 ft. long. These poles are made into three sets held together at the ends by 2x4-in. cross-pieces nailed or bolted. These three sets occupy the first 30 ft. of the box, having spaces between the ends of the sets. The last 10-ft. section of the box narrows gradually to the lower end and is fitted with poles like the other sections, the smaller ends of the poles being placed at the lower end of the section.

The flume is provided with riffles set lengthwise and spaces between the riffle sections. The flume riffles are built in 6-ft. sections, each section composed of five 2x3-in. pieces and provided on two sides with ¼x1½-in. steel or iron strips. The 4-in. spaces between sections provide for the necessary breaking up of clay and gravel. The poles in the dump-box will wear about 60 days. In some cases it has been found more economical to use 20-lb. steel rails instead of poles, but where timber is abundant and the distance is great from steamer landings or railroad stations, the use of poles is more economical. The clean-up usually requires about 3 hr. to a string.

The ground and creek begin freezing about the first of October and the spring thaw permits preliminary work by the first of May. Active scraping can be started in the middle of June. At these claims on Otter Creek the ground to be scraped is not so badly frozen as to require thawing with steam points. When the scraper gets down to frozen ground the work is shifted to another part of the cut and the frozen ground is thawed by the sun in the meantime.

Geological Anatomy of a Tennessee Zinc Mine

By Frank L. Nason*

SYNOPSIS—Origin of ore deposits considered to be in up-flowing magmatic waters rather than down-flowing meteoric waters. In this mine are two vertical fissures 90 ft. apart between which are four distinct rock horizons mineralized to various degrees. Sphalerite, galena and pyrite occur in veins, in irregular sheets on the bedding planes or as metasomatic replacements in dolomite. Probability is that ore will extend to depth.

In a former paper on the "The Zinc Deposits of Eastern Tennessee" (*Engineering and Mining Journal*, Vol. 99, No. 17, p. 734) I attempted to answer the questions: "What is the system of it;" and, "What determined them?"

In the above-cited paper the "system" of the zinc deposits was shown to be a series of strike faults in the Mascot and White Pine belts, resulting in zones of brecciation; in the Powell and Clinch River belts, a series of

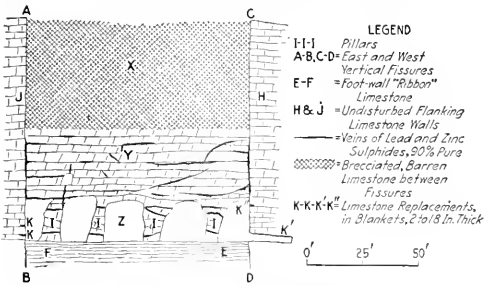

FIG. 1. VERTICAL NORTH AND SOUTH SECTION THROUGH NEW PROSPECT MINE, LEAD MINE BEND, TENN.

profound east and west faults, fractures or fissures, any one or all. The "system," then, is purely one of fissure veins. As to the origin of these ores, the theory of down-flowing or meteoric waters has its ardent advocates; others, myself included, regard these ores as having their origin in profound fissures with upward-flowing waters. The loci of deposition were determined by the flowing of these waters through prepared ground and along lines of least resistance. It is probable that no final and conclusive evidence can be advanced at this time, but the anatomy of the well-known New Prospect mine at Lead Mine Bend, Union County, Tenn., may contribute evidence on a subject that may have economic importance.

Local Topography

The New Prospect mine is located about one mile east of the Powell River. The Powell flows along or near what is evidently the crest of an eroded anticline which strikes ENE. The west leg of the anticline dips NW at an angle, in the main, of 45 deg.; the east, at a much lower angle.

*Geologist and mining engineer, West Haven, Conn.

At Lead Mine Bend there is another anticline which strikes nearly due east, to Straight Creek a distance of about 14 miles. The evidence of this anticline is the outcrop of the underlying Conasauga shales and the "ribbon" limestones lying at the base of the Knox. The resultant of these two folds is a series of dome-shaped hills which rise from 200 to 700 ft. above the waters of the Powell River.

The angle of the strike faults and folds varies between N45 to 65 deg. E. The angle of the cross-folds varies between N90 deg. E to 150 deg. S. The resulting blocks are thus parallelograms, with the acute angle varying from 50 to 60 deg. As is usual in limestone countries,

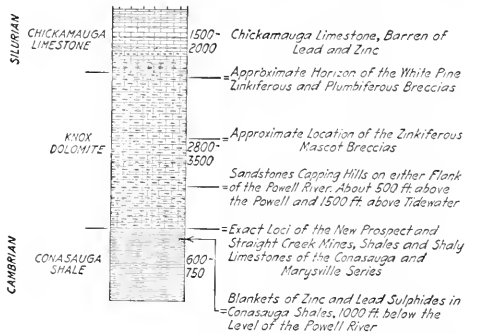

FIG. 2. THE ZINKIFEROUS HORIZONS OF UNION AND CLAIBORNE COUNTIES, TENN.*

the drainage here is almost exclusively underground, with the exception, of course, of base-level streams. The result of these block-fault domes is by this means brought into strong and oftentimes exaggerated relief. There is in other localities equally positive evidence of such cross-folds or faults. It is on one of these domes that the New Prospect mine is located.

Structural Features of the Mine

The structural features of the mine are obvious and are as follows (see Figs. 1 and 2): First, two vertical, parallel mineralized fissures, *A-B, C-D,* about 90 ft. apart; second, between these fissures are four distinct rock horizons—*X*, a horizon about 50 ft. thick, broken between the fissures into small lozenge-shaped fragments barren of mineral except in traces; *Y*, a horizon about 30 ft. thick, strata only slightly fractured and not displaced, mineralized to about 10%; *Z*, the main mine horizon about 20 ft. thick, strata broken and more or less warped with numerous heavily scored slips with east and west striæ, mineralization about 20%; *E-F*, a horizon of ribbon limestone, impure, floor of mine polished but no discernible striæ, strata warped, but not certainly broken, wholly barren of mineral except in the faults as later noted in this article.

*Geological column from Maynardsville Folio, U. S. G. S. Marginal notes by F. L. Nason.

From points *K-K*, for 100 ft. or more due east, is a face of solid limestone which is highly polished with deeply molded scores, rather than striæ pointing east. This is on the north wall of the mine; no similar phenomena are observable on the south wall.

Along the fissures *A-B* and *C-D* there are no apparent vertical displacements of the rock strata save to a very slight extent. These slight displacements are easily explained by one or both of two causes—first, inequality in thickness of the strata, or, second, owing to the fact that the motion was horizontal and the rock strata having a pitch of about 10 deg. to the east.

The whole formation pitches to the east at an angle of about 10 deg. The term pitch is here used advisedly, since it is the relation of the axis of the anticline to the horizon. That there is a northeast fault, somewhere east of the hill on which the mine is located, is evidenced by the fact that the "ribbon" limestones (*E-F*) outcrop at the east base of the hill, instead of the overlying formations *Z*, *Y* and *X*. That there is another fault to the west is again evidenced by the outcrop of the ribbon limestones, which here abut against the edges of the Knox. The hill, then, on which the mine is located is bounded on the south about three-fourths of a mile distant by the eroded crest of an anticline, and on the east and west by two faults which have brought to the surface the ribbon limestones. The vertical throw of the west fault can have been no less than 150 ft. and may have been more. The fourth side, on the north, does not seem to have been disturbed.

Underground, east of the portal, the pillars show the same slips and warped planes, but here, even, save for the two main fissures, no fractures seem to go from zone *Z* into the underlying floor of ribbon limestone, *E-F*. The east breast, about 300 ft. from the portal of the mine, is so covered with broken rock that nearly all structural features are hidden.

The tentative conclusion—not to put it too strongly—to be drawn from the foregoing facts is that these transverse fissures, with their east and west scores and striæ, are the resultants of the orographic movement which formed the general northeast strike of the Appalachian mountain system. In all likelihood these forces were operative before, or at least contemporaneously with, the formation of the cross folds.

Character of the Rocks

The unaided eye can detect no difference between the rocks of the three zones *X*, *Y* and *Z*. They are typical Knox dolomites. In the zone *X* the intense shattering has obliterated all traces of bedding planes. Zones *Y* and *Z* are distinctly bedded. The strata are fairly regular and are from 1 to 2 ft. thick.

Zone *E-F* is evidently an impure limestone and is marked with crenulated bands an inch or more thick. The alternating bands are slaty blue and chocolate brown. The banding shows very distinctly on weathered surfaces, less so, in fact very faintly, on fresh surfaces. Between these limestones and the Knox there is no gradation, the transition being very abrupt. The ribbon limestones are parted by bands of nearly pure slate from an inch up to several feet in thickness. The thickness of the blue or ribbon limestones is not less than 100 ft.

The three sulphides in the order of their abundance are sphalerite, galena and pyrites. These minerals occur in veins as in *A-B, C-D* in irregular sheet-like masses in the bedding planes and as metasomatic replacements of beds of dolomite.

Location and Character of Mineralization

Just where mineralization would seem to occur naturally in the greatest abundance it is almost wholly lacking. This is the brecciated zone *X*. Occasionally there are traces of "face" mineral in the mass of the breccia, but this is rare, the mineralization occurring almost exclusively in the bounding fissures. This lack of mineralization in the breccias is probably to be accounted for in this way: The rocks were here subjected to differential shearing—indicated by the east and west fault lines—to the point of developing pressure planes, but not to the point of rupture. The loose condition noted at present is probably due to weathering, which has sought out and developed the original stress planes. Had these planes been fully developed previously there would probably have been signs of capillary flow at least.

The zone *E-F*, as has been pointed out, is not shattered at all. The lack of bedding planes, or, where these were present, the clay-slate partings, prevented the circulation of mineral-bearing solutions. This seems to be at least a plausible explanation, since where the northeast break occurs west of the mine, brecciation is intense in limited areas. In these breccias the zinc and lead are 10 to 15% of the mass.

The character of the mineralization seems to be determined by the channels of circulation. Where the channels are comparatively open, as in the fissures *A-B, C-D*, and along bedding planes, as shown in the pillars *I-I* and in zone *Y*, the structure is very coarsely crystalline, the minerals being at least 90% pure. There seems to be a tendency for the galena to occur in the middle of the vein, the blende on the sides; but this may not be persistent. In these veins pyrite seems to be lacking.

Where mineralization occurs in breccias the blende and galena are both "dirty," in addition to included fragments, coarse and fine, of the parent rock. I suggest that the "dirt" in the ore is due to finely comminuted rock that was neither swept out nor dissolved by the feeble currents that seeped rather than flowed through the interstices.

In blocks of limestone metasomatically replaced, the ores, almost exclusively blende, are also "dirty," but are due to another cause. The blende replaces the limestone to as high as 80%. At first sight the mass seems to be pure blende. Closer inspection with a pocket lens discloses grains of dolomite alternating with grains of blende, as if molecule by molecule the dolomite had been picked out and replaced molecule by molecule with blende. The texture is as fine-grained as pig iron, or even finer. Here is by far the greater amount of pyrites. There are to be seen now in the old mine blocks of this replaced ore the full size of the pillars. These beds thus appeared to have reached almost continuously across the entire width of the ore horizon. It is probably true that the points *K-K*, later referred to, are the evidences of the extent of these replaced beds. Farther back in the mine, to the east, the rock floor of the mine seems to have been raised, and here there are more than traces of replacement of small bands of the ribbon limestone.

The metasomatic replacement is very beautifully illustrated in many places in the mine. Beds of dolomite

partly replaced, appear as if a corroding stream had flowed over them, etching deep potholes, as before, molecule by molecule, and filled the etched space with a mixture of blende and dolomite. In places the blende appears in a cloudlike mass in the center of a stratum, with no apparent port of entry. The replaced limestone may be six inches or more in diameter, and from this down to mere grains of blende.

The tentative conclusion drawn from the mineralization is almost strong enough to be classed as positive and inevitable that it came from an upward-flowing stream, since all the various forms in which it occurs are directly connected with the two vertical fissures. If it is logically allowable to connect these fissures with the profound Appalachian orographic movement, they are, *a priori*, profound as well. Some fissures in this region have been followed 1200 ft. below base level of drainage, 200 ft. below sea level, and more or less mineralization precisely similar to that observed in the mine is found to the lowest point reached.

Length of Mineralization on Strike

About 600 ft. to the west of the section shown in Fig. 1 the slope of the hill cuts the unmineralized floor of the mine. East of the above-mentioned section the underground workings extend a maximum distance of 500 ft. The axial extent of the New Prospect mine is thus 1100 ft. For a distance of 800 ft. the orebody, save for zone Y, seems to have been worked for the full space between the two fissures 90 to 100 ft. To the west of this section (Fig. 1) the ores were all oxidized and the mine was worked as an opencut. Disregarding the slope of the hill, the cubic contents of the orebody, $1100 \times 90 \times 50$ ft., is 4,950,000 cu.ft.

As to the persistence in depth of the two main fissures of the mine, there is no direct evidence. About 1000 ft. to the west, east-and-west striæ were found to a depth of over 400 ft. This was in the pure Conasauga shales. Two miles or more SSW, striæ as before, in what appear to be well-defined fissures, were found 700 ft. below the surface. Two and one-half miles NNE the same phenomena appeared at a depth of 1200 ft. Geologically this equals a depth of 1350 ft. The fissures were in Conasauga shale. The fissures were followed from the surface to the bottom. It hardly seems to be reasonable to insist that the two New Prospect fissures will not extend as deep.

Coördination of Data

While freely confessing that I am convinced of the fact that the source of zinc and lead ores of the eastern Tennessee belt and of the entire limestone formation along the entire western foot of the Appalachian mountains has a profound-fissure origin, I have tried to state, without color, the salient features of the structure and occurrence of the mineralization of the New Prospect mine. It remains to coördinate the data presented herewith with other data with which they seem to be inseparably connected.

In the first place, attention is called to the general structure of the entire field. There are ENE strike folds and faults. In places these strike folds have terminated in great overthrust faults where the underlying eastern beds have been thrust over the upper western members of the formation. There is conclusive evidence that the Powell River flows on or near the crest of an eroded anticline. There is also evidence that there are other great folds where the underlying shales have been brought to the surface.

There is also indisputable evidence of cross-folds equally profound. From Lead Mine Bend on the Powell there is certainly an anticline reaching nearly due east to Straight Creek, a distance of 14 miles. Based on drill-holes, there is evidence of other easterly folds that have not brought the underlying shales to the surface; but the folds are certainly 500 ft. high. These folds are parallel to the Lead Mine Bend fold. The resultant of these two systems of anticlines is a series of folds similar to a system of groined arches.

It seems hardly possible that these forces, acting through a visible thickness of 1500 ft. and 1200 ft. below base level of drainage, could end in other than faulting equally profound. With such structural effects—not at all local but general—it would seem to be allowable to go still farther and to affirm that the movement must have extended at least through the entire thickness of the Paleozoic series to a depth of over 6000 ft. As a matter of fact, the movement in this series seems to be more reasonably classed as orographic rather than local, and to be inseparably connected with the movements which resulted in the great Appalachian mountain system. In this case the fissure depths would be far greater than the 6000 ft. of the Paleozoics. It is hardly necessary to call attention to the fact that the Appalachian resultant was a slow growth and development and was not at all cataclysmic.

With this tentative conclusion goes another of even greater economic importance. Whether the facts cited in my former paper of zinc and lead occurring in veins in the pre-Cambrian be allowed weight or not, the fact of lead and zinc occurring in fissures 1200 ft. below base level of drainage in the valley of the Powell must preclude the origin of these ores from downward-flowing waters. Even allowing for all possible changes in topography, the flow of circulating meteoric waters must have been from, not toward, this point.

Again, forging a more or less attenuated chain of reasoning, it seems that the two main lines of fissures in the New Prospect mine cannot prove to be an exception to the fact that adjoining fissures are deep and are mineralized as far as they have been tested. Of course it will be borne in mind that the fissures and their mineral contents occur on axes of, what at least seem to be, profound orographic movements.

Tentative Conclusions

If the facts cited in this paper are undisputed, the profound-fissure origin of the ores of eastern Tennessee is an established fact. The economic value of such a demonstration is great, but is not immediately available. The east and west length of the Powell and Clinch River fissures are known to be over 14 miles long, and are probably much longer. These lines are not continuously mineralized. There may be and probably are many more mineralized points than are now observable, since the greater part of the surface of the country is covered by a heavy mantle of residual clay. Were one to be convinced as to the truth of my deductions to the point of prospecting for an ore deposit, just where would he do his prospecting?

The superficial dimensions of the one completely known mine are as stated—1100 × 90 ft., a total area of 99,000 sq.ft. As to depth below the surface, this may be as great as or greater than 1200 ft.

The Straight Creek and New Prospect mines are the only ones now known in this section and in this position relative to the Knox at its base. Whether the numerous fissures which appear on the surface in this part of Tennessee will, with depth, make orebodies equal to these, is as yet unknown. In such a case a great future as a zinc field is certain. In considering this question practically, this must be remembered: There has been very little skilled geological study of this field. Little money has been available for careful and consecutive study. What this field would be today had it, for example, had the same careful study as has been possible in the States of New Jersey and New York, it is impossible to say. What is, is only evident after careful investigation, but is the "what" economic or the reverse?

Spanish Potash Deposits

A report from Consul-General C. B. Hurst at Barcelona, Spain, says that the stoppage of shipments of potash salts from Germany by the war has called attention to the potash deposits that were known to exist near Barcelona. Borings and analyses had been repeatedly made with reference to the region where the salts abounded in the Spanish provinces of Barcelona and Lerida. The results have been particularly favorable, but it will require the employment of capital and enterprise to make potash in this neighborhood a commercially profitable product.

In the various borings near the town of Sarria potash salts were found at depths between 121 and 197 ft. and another deposit at 426 ft. At 886 ft., the greatest depth attained, important quantities of potassium compounds were found to rest on a stratum of white salt not yet pierced. In the area tested by borings comprising some 2,690,000 sq.ft., there were estimated to be approximately 2,550,000 tons of carnallite and 1,150,000 tons of sylvinite, which should produce a total of 3,675,000 tons of potassium salts.

From the general characteristics of the region it is considered probable that there are further deposits in greater or less proximity to those already tested. In a stream running by the salt works of Cardona there is a large percentage of potash in solution, and it has been discovered that quantities of potash have already been allowed to go to waste in the salt mines that might have been profitably used.

On account of the exceptionally irregular geological formation of the country near Barcelona it is difficult to make exact valuations of the amount of potash salt that can be mined. Nevertheless, the presence of certain gypsum beds and the potash-holding streams will serve as a guide to determine the continuation of the potash deposits.

Particular interest has been displayed in these potash deposits by people in the United States. Persons have sought to buy concessions or land in which the deposits are situated, or have been willing to make contracts for regular shipments to the United States. One large tract is already owned outside of Spain, but in view of the great national importance of the deposits the Spanish Government is taking measures for their supervision, if not for their exploitation.

Because of the small available supply for use at the present time in Spain the export of potash from this country is forbidden provisionally.

In small quantity potash is obtained here by the evaporation of the water used in scouring wool and also in larger bulk from the residue left from the manufacture of beet-root sugar. Shipments of this latter variety, limited and known here commercially as black salts, have been made to the United States and to Great Britain.

Further advices from sources outside the report given are that boring and exploration have failed thus far to show potash salts in layers thick enough or of an extent sufficiently large to promise developments of great commercial importance. The real extent and value of the deposits are still to be ascertained.

Tin Exports from China

Consul-General G. E. Anderson at Hongkong writes that the course of the exports of tin from southern China in the immediate future is somewhat uncertain. The effects of the war in general are unfavorable, and the further fact that the tin coming out of Indo-China must pass through French territory, where it is regarded as contraband and subject to restrictions of various sorts when it is allowed to pass at all, have rendered trade even more difficult.

At the opening of the year there was on hand in Hongkong a stock of about 1000 tons of tin. Since then the stock has increased to about 1700 tons, in spite of the fact that the amount of tin coming out of Yunnan since the opening of the war is in materially smaller volume than usual. Explanation seems to lie in the disposition of the trade earlier in the year to move stocks when fair prices could be had. The exports of tin from the Mengtze district in 1914 were 5613 long tons, against 6414 in 1913. For the period Jan. 1 to May 15, however, the exports increased from 1566 tons in 1914 to 2034 tons this year.

At the close of the first quarter of the current year the Hongkong Government assumed control of the trade as that in contraband by prohibiting the export of tin to all destinations other than the United Kingdom and British possessions and protectorates. After several weeks' agitation permits were issued for the export of tin to the United States by making all consignments to the British consular officers in the American ports concerned so that the actual consignees might be known. The exports to the United States have been going forward in fair volume. The present quotation of the highest grade tin is $97 local currency per picul of 133⅓ lb., or at present exchange about 32.75c. gold per lb.

Ferromanganese Made in the Electric Furnace is being shipped from California, according to the "Iron Age." The Noble Electric Steel Co. has recently shipped two carloads, or about 60 tons, of ferromanganese produced at its plant at Heroult, Shasta County, Calif. The purchaser is understood to be an eastern Pennsylvania steel works and the price $100 per ton, f.o.b. The San Francisco company, it is stated, is now in a position to provide all the ferromanganese needed on the Pacific coast, as a second furnace is to go on ferromanganese. Two other furnaces are to make ferrochrome, for which the price is $200 a ton. The fifth furnace will be held in reserve. Ore for the manufacture of ferromanganese is being brought from Mendocino County, Calif.

Metal Losses in Copper Slags—II

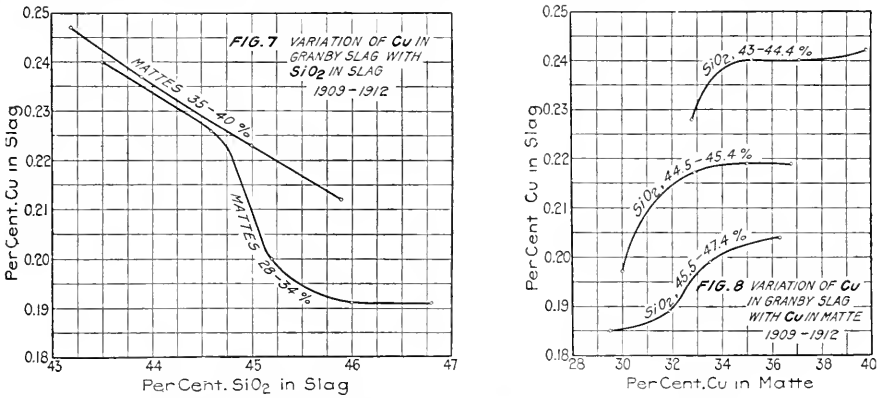
By Frank E. Lathe*

SYNOPSIS—The results of laboratory investigations are presented, together with numerous determinations on regular furnace products of the Granby works at Grand Forks, B. C., where extended settling experiments and deepening of the furnaces resulted in lower slag losses. The presence of sulphide copper in slags does not preclude the presence of oxidized copper, especially the silicate.

In my review of the laboratory investigations of the metal losses in copper slags will be included not only the results of my own experiments and the numerous determinations made on regular furnace products to obtain desired information, but also the graphic representation of results of commercial blast-furnace smelting as carried out at the Grand Forks, B. C., plant of the Granby Consolidated Mining, Smelting & Power Co., Ltd. As the Granby's practice covered by this paper extends over a period of seven or eight years, and certain metallurgical changes were made during that time a review of these will first be given. A more detailed report of operations up to December, 1909, will be found in my article in the *Journal* of the Canadian Mining Institute, 1910, Vol. 13, p. 273.

The original Granby blast furnaces were made (1900) 44x160 in. at the tuyeres, and 8 ft. 11½ in. from feed floor to center of tuyeres. They are enlarged to 44x213 in., and then after a considerable period of operation both lengthened and deepened, the new measurements of six of the eight furnaces being 44x266½ in. at the tuyeres, and 12 ft. 10 in. from feed floor to center of tuyeres. This resulted in a more uniform running of the furnaces, greater tonnage, less coke, hotter matte and slag, and owing to the weaker oxidizing action, a lower grade of matte and more siliceous slag. The effect upon the copper content of the slag will be considered later, although a cleaner slag, as a result of the new conditions is a foregone conclusion. Since that time no changes have been made in the furnace construction, but settlers of different sizes and shapes have been experimented with. The company is now adopting as its standard, a small tapered settler, and it seems desirable to have three or more of these in series, the slag cascading from one to the next. The advantage of the tapered form is that when the settler partly fills with metallics, which are usually formed under similar conditions of siliceous slag and high coke, the shell may be readily lifted off the base and the sow disposed of without difficulty. With these explanations the following pages will be more easily understood.

During a year (1907) of operation with low-ore column the average analysis of Granby furnace products was as follows: Matte, Cu, 40.94%; slag, Cu, 0.322%; SiO_2, 44.28; FeO, 21.60; CaO, 22.77; Al_2O_3, 7.23; MgO, 3.50. During this time slag samples from individual furnaces would occasionally carry abnormally high copper —up to 0.45% or higher—and in some instances these slags showed a distinct reddish appearance. They were believed to be the result of over-oxidation, an opinion founded on the unusual conditions prevailing at such times.



FIGS. 7 AND 8. VARIATION OF COPPER IN GRANBY SLAG, 1909-1912

During the five or six years since the furnaces were deepened no such appearance has been observed, and the number of foul slags, as well as the average copper content of normal slags, has been materially reduced. For a period of three years immediately following the deepening of the furnaces matte and slag averaged: Matte, Cu, 34.45; slag, Cu, 0.216; SiO_2, 45.07; FeO, 19.39; CaO, 22.64; Al_2O_3, 8.98; MgO, 3.60. All the weekly average determinations of copper made during this time, covering the production of three million tons of slag, have been classified according to the acidity of the slag and the grade of the accompanying matte. From the figures thus obtained the curves in Figs. 7 and 8 have been plotted. Fig. 7 shows the decrease of copper as the silica in the slag increased for mattes of 28-34% and 35-40% Cu, and in Fig. 8 the increase of copper in slags with the grade of matte for slags of 43.0-44.4% SiO_2, 44.5-45.4%,

*Chief chemist, Granby Consolidated Mining, Smelting & Power Co., Ltd., Grand Forks, B. C., Can.

and 45.5-47.4%. Each point as shown represents the result of smelting during a period of from 6 to 30 weeks, such averages being necessary to hide numerous small irregularities in the curves due to a variation in conditions other than those now being considered. Determinations of copper in mattes were made by the cyanide method, in slags by electrolysis, and silica in the slags by one evaporation only—the true silica is about 0.6% higher.

Copper Content of Granby Slags with Varying Silica

In considering the first series of curves, Fig. 7, it will be noticed that the decrease of copper in the slags with the increase of silica was very uniform when the higher mattes were being produced. The curve for the lower mattes almost coincides with this one till the slag reaches 45% in silica, when the decrease of copper is rapid. At 45-46% SiO_2 the difference of 6% in the matte is seen to have changed the copper content of the slag about 0.02%. Judging by the last two points on this curve one would conclude that with these highly acid slags the limit of copper reduction had been reached, as far as the influence of silica was concerned. This is probably not altogether true, as indicated by the more reliable curve in Fig. 9, although the viscosity of these slags increases more rapidly with each per cent. of silica than it does with the more basic slags. The average slag produced during this whole period gives oxygen ratios in acid and base as 2.32 : 1, 1.46 : 1, or 1.97 : 1, according as the alumina is classed with the acids, with the bases or omitted from the calculation altogether. The three ratios are given as metallurgists seem quite unable to agree upon any particular one.

The other series of curves, Fig. 8, is perhaps more interesting and instructive, though representing exactly the same practice. The silicas of the three curves average about 43.8, 45.0 and 46.2%, so that a difference of 1.2% in the silica corresponds to a change of about 0.02% in the copper. From the nearness of the two curves in Fig. 7, it may be seen that the grade of matte did not greatly affect the copper content of the slags with 43.5-44.5% SiO_2. This is demonstrated here by the very flat curve for low silica, but it also shows now that the constant value is particularly for mattes of 34-39% Cu. Within these limits all the curves flatten considerably, as did those[1] plotted by Messrs. Heywood, Wright, and Wanjukoff.

An attempt was also made to plot curves for the iron and lime content of these slags, but they did not show sufficient regularity, the effect of variation in either being obscured by the changes of silica. The averages did indicate, however, that the replacement of FeO by CaO had resulted in cleaner slags, as might be expected.

Recent Granby practice is covered by another curve, Fig. 9, the period of operation being from Oct. 6, 1913, to July 5, 1914, during which time daily electrolytic copper assays were made on the average slag from all furnaces. This curve has been called more reliable than those of Figs. 7 and 8 because conditions seldom change greatly within 24 hr., whereas a weekly average slag of 45% SiO_2 may occasionally be made up of others varying all the way from 41 to 47%. So also other conditions may have varied. Averages were also calculated for different grades of matte, the two classes 27-31% and 32-35% being made, but the copper content of the latter averaged only 0.003% higher than the former, with some irregularity, which made it useless to plot the values obtained. Hence all mattes of 27-35% are grouped together. The curve is seen in this instance to assume nearly the form of a straight line, and the decrease of copper with increase of silica is not nearly so pronounced as before. Comparing this curve with the one in Fig. 7 for mattes of 28-34% and silica of 44.5-45.0% one finds lower copper in the later slags by 0.015-0.003%. The greatest change in the method of operating during this time, as already indicated, was to provide additional facilities for settling, and the results thus obtained with a slag which would be termed already "clean" are well worth considering. These slags of not over 45% SiO_2 were the more fluid ones, and responded to the additional opportunities for settling to a greater extent than did the more highly siliceous slags. It should, however, be borne in mind that when those of 46-47% SiO_2 (Fig. 7) were being produced the experiments in settling were already under way and this part of the curve is thus transitional.

To summarize this discussion and show the steady progress that has been made for some years in reducing the copper losses the average copper in the slag for each year from 1907-1914 has been plotted in Fig. 10. The importance of these results is better seen by considering the amount of copper saved per year in this way by the Granby company, taking its annual output as one million tons of slag, a figure closely approximated when the smelting operation is not interrupted. On this basis, a saving of 0.01% Cu in the slag amounts to 200,000 lb. of the metal per year, so the 1914 practice was better than that of 1907 by 2,640,000 lb. With copper at 12c. per lb. these amounts are worth $24,000 and $316,800, respectively.

Copper Oxide in Granby Slags

The percentage of copper oxide in Granby slags, by calculation from the gold content, was studied. The amount of gold in Granby furnace products is not large, hence to be of any real value the figures should show an average over a considerable period of time. Those given below are made up of averages of the daily assays from August, 1909, to December, 1912. The gold in the slag was regularly determined by parting together the beads from 20 assay tons of sample. Silver contents are not shown, as the assay for silver in the slags was not made with regularity.

The method used is that suggested by Mr. Channing, and is based on the assumption that matte particles suspended in slag carry the normal amount of copper, gold and silver, and that if more copper is found there than would be indicated by the gold content it has probably been oxidized. This is best shown by giving the ounces of gold per ton of contained copper, and not per ton of matte or slag.

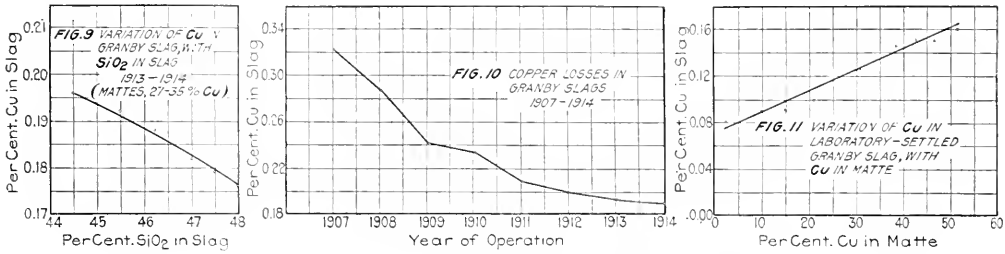
Gold per ton copper in Granby matte	4.412 oz.
Gold per ton copper in Granby slag	1.398 oz.
Per cent copper as sulphide in slag $\frac{1.398 \times 100}{4.412} =$	31.7
Per cent copper as oxide in slag $100 - 31.7 =$	68.3

In determining the percentage of copper oxide in Granby slags under different furnace conditions, a series of experiments was begun without a detailed knowledge

[1] "Engineering and Mining Journal," Aug. 7, 1915.

of Mr. Kiddie's method, and different strengths of sulphuric acid were tried for the decomposition of slags —from 2-25%. In each case the acid was boiled, and the results showed that high, though varying, quantities of copper had been dissolved. Apparently, as noticed later by Mr. Wanjukoff, sulphuric acid was not satisfactory as a solvent for copper oxide. In a private communication, however, Mr. Kiddie advised carrying out the experiments at a temperature not exceeding 80° C., suggesting that boiling had caused the formation of ferric compounds, which had in turn attacked the sulphides of copper. Following his advice the experiments were repeated, the time being varied from 1½-3 hr. and the temperature from 60-80° C., H_2SO_4 (1:20) being used in each case. The percentages of copper dissolved under these varying conditions agreed within 0.005%, a strong indication that the sulphide was not appreciably attacked. While such evidence was was due to sulphide passing through the filter than to a solution of the copper, for hydrogen sulphide was present in the liquid and this will cause a distinct turbidity with 0.00007 gram Cu in 100 c.c. of weak acid, as proved by trial. Even if it were a solution of copper it seems that the amount dissolved from the matte particles in two grams of slag would be negligible. The degree of solution of iron in the matte is seen by the fact that the residue filtered off gave only 3.4% Fe, as against 38.9% in the original matte. On the whole, there appears to be reason for believing that the copper oxide in slags, as determined by weak sulphuric acid, is less than the actual amount rather than greater.

Hydrochloric acid was also tried as a solvent. One gram of 38% matte was treated with dilute HCl (1:20) as in the case of the first sulphuric-acid experiment. As the acid solution could not be electrolyzed directly it was filtered, 7 c.c. H_2SO_4 were added, and the



FIGS. 9 TO 11 COPPER IN GRANBY SLAG AND IMPROVEMENT IN GRANBY PRACTICE, 1907-1914

at the time considered almost conclusive, it was decided later to investigate the question more fully, as the value of the results depended entirely on the accuracy of this determination.

One gram of 38% matte was treated with H_2SO_4 (1:20) for 1 hr. at 70° C. It was then allowed to stand over night at room temperature, when it was further warmed to 70° C. for 2 hr., having been thoroughly stirred every few minutes during the period of heating. There was at first a strong evolution of hydrogen sulphide, and at the end of the treatment the residue was black. Considerable finely divided cuprous sulphide was held in suspension, and when the solution was electrolyzed without filtering some of this seemed to deposit on the cathode. There was no appearance of metallic copper. After a current of 1.25 amp. had been passed for 3 hr. the cathode was removed, washed and placed in dilute nitric acid for a few minutes, when it regained its usual bright appearance. This solution was then electrolyzed and copper was deposited, bright in color, and weighing 0.0020 gram.

As it appeared that this result was due entirely to the adherence of cuprous sulphide and not to any solution of copper, another similar portion was treated with H_2SO_4 (1:20) for 3 hr. at 70° C., the residue was filtered off and the filtrate electrolyzed. The cathode lost its bright color during the electrolysis, but was much cleaner than in the previous experiment and again showed no metallic copper. The nitric-acid treatment and subsequent electrolysis were also carried out and this time 0.0004 gram of copper was deposited, being barely visible on the platinum. It seems more likely that this liquid was evaporated to white fumes. It was then diluted, boiled and electrolyzed, the treatment with nitric and redeposition being also carried out, when 0.0012 grams of copper was deposited. The residue of sulphide from the hydrochloric treatment gave no trace of iron. Mr. Kiddie suggested (private communication) that the total oxidized copper—even as Cu_2O—would be given by dilute HCl and NaCl. To test two grams of a slag giving 0.205% Cu as oxide by H_2SO_4 treatment out of 0.32% total copper were warmed at 70° C. for 2 hr.—decomposition appeared complete in ½ hr.—with HCl (1:20) and 1½% NaCl. The liquid was filtered, washed with more solvent and copper was determined in the filtrate by precipitation as sulphide, oxidation, solution in nitric acid and electrolysis. The result, 0.255% Cu, might appear to show the presence of Cu_2O, but against this are the close agreement of calculated oxide and oxide determined with H_2SO_4 on Granby slags, given in the next paragraph, and the slight solubility (?) of Cu_2S in HCl already mentioned. Hydrochloric acid was not further experimented with.

The treatment given Granby slags for the determination of CuO was as follows: Two grams were weighed into a tall beaker and digested for 2-3 hr. at 60-80° C. with 150 c.c. H_2SO_4 (1:20). The water-cooled slags decomposed readily under such treatment. At the end of the time the solution was electrolyzed without filtering, as there is always a loss in filtering Granby slags decomposed with H_2SO_4, owing to the large quantity of $CaSO_4$ formed. The copper was then dissolved in weak HNO_3 and redeposited before the final weighing. The sulphide was always found by difference, determinations being

made in the ordinary way for total copper on another portion of the sample. Additional details and precautions are given in my article[2] in the *Journal* of June 1, 1912.

Agreement of Copper-Oxide Determinations

The first effort was to learn if the percentage of oxide by this method would agree with that calculated from the gold value, previously mentioned. Unfortunately the samples had not all been kept, but an average was made up which represented normal running of the furnace at that time. Its composition was found to be: SiO_2, 45.3; FeO, 19.2; CaO, 23.5; total Cu, 0.235; oxide Cu, 0.160; oxide ratio, 68.1 : 100. This result is surprisingly close to the calculated value.

It was desired also to determine the oxide in some of the slags abnormally high in copper, which were made before the deepening of the Granby furnaces. These being slags from single shifts on individual furnaces had not been kept separated from others. Of the averages available one was chosen representing the slag from all furnaces for a period of one month, and it gave results as follows: Total Cu, 0.345; oxide Cu, 0.245; oxide ratio, 71 : 100. Here both the oxide and sulphide copper are higher and the ratio increased somewhat. The change in ratio is better seen when expressed as follows:

Sulphide copper	0.100 instead of 0.075, or 33.3% higher
Oxide copper	0.245 instead of 0.160, or 53.1% higher

This is what might be expected from the more oxidizing conditions with low ore column.

Occasionally slags from individual furnaces carry more than the normal amount of copper. For some months in 1912 all such slags, found in the daily colorimetric work, were saved, being put into two classes, those with about 0.30% Cu and those near 0.40%. An average of all those (51) of the former class, assaying 0.28% total Cu, gave 0.19% oxide Cu, or 67.9% of the total, practically the normal ratio. The higher slags (3) assaying 0.43% total Cu, gave 0.247% oxide Cu, or 57.4% of the total. This ratio is materially lower, and is instructive in showing that the higher loss of copper was due in great measure to poor settling, due probably to the slag being too cold for the proper separation of matte, as the Granby slags, which are unusually low in iron, have always a low specific gravity.

Normal slags in 1914 gave the following results: SiO_2, 47.0; FeO, 17.1; CaO, 22.2; total Cu, 0.195; oxide Cu, 0.115; oxide ratio, 62.5 : 100. It thus appears that not only have both the sulphide and oxide copper been reduced in quantity, but their relative proportions in normal slags have changed to some extent.

While discussing the question of loss of copper as oxide it may be mentioned that several times a siliceous ore, carrying chrysocolla and chalcocite, and normally used for lining the old acid converters, was added to the charge of the blast furnaces. In each case the copper lost in the slag increased materially, and the idea of smelting this ore in the blast furnaces when the Granby ores were sufficiently low in silica had to be abandoned. None of these slags have been available since this series of experiments was started, but apparently the copper charged as silicate did not entirely free itself from this combination in passing through the furnace.

[2] "Copper Determinations at Granby," by F. E. Lathe, "Eng. and Min. Journ.," 1912, Vol. 94, p. 1071.

The condition of copper in converter slags has been debated without much definite proof on one side or the other. The figures here given show the result of normal operation for a period of one week of the Granby's three basic converters: SiO_2, 21.85; S, 1.40; total Cu, 1.73; oxide Cu, 1.39; oxide ratio, 80.3 : 100. While the sulphur present was more than sufficient to combine with all the copper four-fifths of the latter nevertheless united with oxygen.

Experiments in Settling Granby Slags

While it is true, as pointed out by Mr. Grabill, that one cannot say definitely how his laboratory experiments in settling slags may have been influenced by time, temperature, container, furnace gases and all other artificial conditions, something may nevertheless be learned by this kind of work. It may point the way to the more encouraging lines of experiment in actual furnace operation if only one condition at a time has been changed in the laboratory. With this in mind the following experiments were tried.

Ten charges, as shown in Table 4, were made up in 20-gram fireclay assay crucibles, and these were fused in the firebox of an ordinary coal-fired assay furnace. The matte, copper and ferrous sulphide were in each case placed in the bottom of the crucible and the slag, crushed to 20 mesh, poured over them. The slag contained: Cu, 0.23; SiO_2, 45.3; FeO, 19.2; CaO, 23.5. The charges

TABLE 4. LABORATORY SETTLING EXPERIMENTS WITH GRANBY SLAG

Charge-grams				Products	
Matte 37.6% Cu	Copper 99.0% Cu	FeS	Slag	Matte % Cu	Slag % Cu
5	2	..	100	51.6	0.16
5	1	..	100	46.9	0.15
5	0.5	..	100	42.4	0.15
5	..	..	100	38.8	0.145
5	..	1	100	30.6	0.125
5	..	2	100	28.5	0.125
5	..	5	100	21.3	0.10
5	..	10	100	15.2	0.09
5	..	20	100	9.6	0.09
..	..	20	100	2.7	0.08

were kept in the furnace in the fused condition about an hour, at a temperature of 1250-1350° C. (The average temperature of Granby blast-furnace slags leaving the furnace spout is 1275° C.) They were then carefully removed, the contents being kept as quiet as possible and allowed to cool. When cold, the crucibles were broken, matte and slag separated, bucked and assayed. A calculation shows that there is some apparent discrepancy between copper in the various charges and that found. When this was observed the ferrous sulphide was tested and found to contain a small amount of copper. That the gases did not materially affect the grade of matte is best seen in the fact that when nothing but slag was fused with the matte its grade did not greatly change.

Analysis of Air-Cooled Slags

As these slags were air-cooled, ordinary methods did not suffice for their complete decomposition. Large platinum dishes not being available the following procedure was adopted:

Two grams of slag were warmed for 10 min. in a tall 200-c.c. beaker with 6 c.c. HNO_3. Then 2 c.c. HF were added, and the whole heated till the action diminished. After cooling, 8 c.c. H_2SO_4 were gradually added, and when the liquid became quiet it was transferred to a platinum crucible, in which it was evaporated to copious

fumes. (The whole operation may be made in beakers, but more HF is necessary and the glass is badly corroded.) It was then cooled, transferred to a beaker for electrolysis, warmed with a little water and diluted to 150 c.c. After the addition of 2 c.c. HNO_3 the solution was electrolyzed without filtering. The precipitated copper was dissolved in HNO_3 and redeposited, and the platinum cylinder—after the usual cleaning—was reweighed, to correct for any platinum carried over by possible traces of HF. The limit of experimental error by this method is probably about 0.01%.

Increase of Copper in Slag with Grade of Matte

The results have been plotted in Fig. 11 and the straight line drawn is seen to pass within 0.01% of each point. This nearly uniform increase of copper in the slag with the grade of matte is to be expected from the experience of ordinary furnace operation, but the peculiar thing about it is that the line does not point to the origin, and would cut the axis at about 0.07% Cu in the slag.

It is unfortunate that the copper oxide in these slags could not be determined accurately by Mr. Kiddie's method, owing to the incomplete decomposition with H_2SO_4. When the usual treatment was carried out the copper dissolved varied irregularly from 0.04-0.10% in the 10 samples, averaging 0.062%, or 51% of the total copper. Undecomposed slag could still be seen in all cases after the H_2SO_4 treatment, so that this percentage is lower than the actual one. It would have been interesting, had it been possible, to calculate the oxide from the gold content, as illustrated, but the amount of clean slag obtained in these experiments was far too small for an accurate determination of such minute quantities of gold.

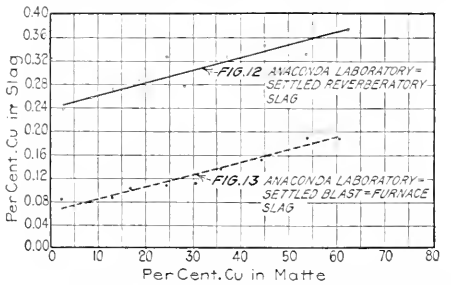
Comparing this curve with the middle curve of Fig. 8, which it approximates in composition, we see between 30% and 38% mattes an average difference of about 0.09% in the copper content of the slag, the copper remaining in the experimental slags being only 58% of that normally found in furnace operation. Even the settling of all the sulphide would not have produced a result so low as this, showing that some of the oxide must also have been reduced.

Experiments with Anaconda Slags

On visiting the Anaconda Copper Mining Co.'s smelting works at Great Falls and Anaconda, Mont., in the spring of 1914, I was given such samples as were requested for experimental purposes, and my thanks are due to the management of both plants for these and many other courtesies extended.

In Great Falls one furnace is 84x180 in. at the tuyeres, and 22 ft. 3½ in. from feed floor to center of tuyeres, the vertical section resembling that of an iron blast furnace. It is described and illustrated in Doctor Hofman's "Metallurgy of Copper," pp. 164 and 165. It receives at varying pressures about 17,000 cu.ft. of free air per min. from a constant-volume General Electric turbo-blower. The charge varies considerably, but the sulphur content will average about 15%. The furnace is provided with one 15-ft. settler. A sample of the slag, said to be typical, gave on analysis the following result: SiO_2, 36.6; FeO, 30.7; CaO, 20.8; total Cu, 0.280; oxide Cu, 0.140; oxide ratio, 50:100. While no real comparison can be made between this and Granby slags, which are formed under radically different conditions, it may be noticed in passing that this percentage of oxide copper is the same as that normally found in Granby slags of 0.21% Cu, though the ratio of oxide to sulphide is 1:1 instead of 2:1. Probably this is largely due to the fact that the percentage of sulphur on the charge is fully five times as great as at Grand Forks.

At the Washoe smelting works at Anaconda samples were obtained of both blast- and reverberatory-furnace slags. The averages for one month analyzed—all except copper by Washoe chemists—as follows: Reverberatory matte, Cu, 40.91%; reverberatory slag, SiO_2, 38.1; FeO, 42.3; CaO, 5.6; Al_2O_3, 7.4; ZnO, 1.7; total Cu, 0.425; oxide Cu, 0.315; oxide ratio, 74.1:100; blast-furnace matte, Cu, 44.48; blast-furnace slag, SiO_2, 39.0; FeO, 25.2; CaO, 24.2; Al_2O_3, 7.3; ZnO, 0.9; total Cu, 0.320; oxide Cu, 0.205; oxide ratio, 64.1:100. The higher percentage of oxidized copper in the first of these may be due to the oxidized charge, and it would be interesting to know if this is usual in reverberatory furnaces smelting roasted concentrates. The sulphide copper is almost the same in the two. In settling the sulphide the reverberatory furnace has the advantages of a lower matte and longer contact of molten matte and slag, the blast furnace that of lower specific gravity of slag.



FIGS. 12 AND 13. VARIATION OF Cu IN ANACONDA LABORATORY-SETTLED SLAG WITH Cu IN MATTE

In addition to the monthly averages, samples of one day's run in quantities of several pounds were secured. The reverberatory slag contained the following: Cu, 0.490; SiO_2, 36.3; FeO, 44.4; CaO, 4.6. With this slag a series of experiments in settling was carried out similar to the one described for Granby slag. Charges and results are shown in Table 5. Fig. 12 shows these results plotted, and though the irregularity is greater than that of the Granby slag similarly treated, the general form is still a straight line. This also does not point to the origin, but would indicate a low limit of about 0.23% Cu in this slag. With a matte of 41% the slag holds 0.335% Cu, or only 0.09% below the

TABLE 5 LABORATORY SETTLING OF ANACONDA REVERBERATORY SLAG

Charge-grams				Product	
Matte 32.2%	Copper 99.0% Cu	FeS	Slag	Matte % Cu	Slag % Cu

5	...	10	100	13.1	0.270
5	...	20	100	8.5	0.257
...	...	20	100	2.7	0.235

month's average already given. This shows the efficiency of reverberatory settling, in spite of a heavy slag. These experimental slags were but slightly attacked by ordinary acids, rendering the use of hydrofluoric acid necessary for their decomposition. The determination of copper oxide was not possible by the method adopted for water-cooled slags, so was not even attempted.

The results of a similar series of experiments with Anaconda blast-furnace slag are shown in Table 6 and Fig. 13. This slag analyzed: Cu, 0.305; SiO_2, 37.4; FeO, 25.1; CaO, 25.4. The line of Fig. 13 is similar

TABLE 6. LABORATORY SETTLING OF ANACONDA BLAST-FURNACE SLAG

Charge-grams				Product	
Matte 32.2%	Copper 99.0% Cu	FeS	Slag	Matte % Cu	Slag % Cu
10	6	0	100	60.2	0.185

10	0	1	100	30.2	0.110
10	0	4	100	24.1	0.105
10	0	10	100	16.7	0.100
5	0	10	100	12.8	0.085
5	0	20	100	8.0	0.070
0	0	20	100	2.1	0.082

to that of Fig. 11 for Granby slag, not differing by more than 0.01% Cu at any point. The slag with matte of 44.5% has 0.155% Cu, against 0.32% for the month's average blast-furnace slag. This is lower than the oxide copper in the monthly average and shows that some oxide was reduced.

While these experimental slags were slowly cooled they all decomposed readily either with HNO_3 or H_2SO_4. As this made possible the determination of copper oxide, it was carried out. Although the 10 slags were run together under exactly the same conditions of time, temperature, strength of acid, etc., there was little regularity in the results. The oxide varied from 25-61% of the total, and averaged 39.2%, considerably lower than the 51% of the Granby experimental slags.

Presence of Sulphide Copper Does Not Preclude Oxidized Copper

Some experiments were undertaken to determine the action of matte on copper oxide and silicate. The chief argument against the existence of copper in slags in the oxidized condition has been based upon the well-known reaction:

$$Cu_2S + 2CuO = 4\,Cu + SO_2$$

As this reaction may take place whenever copper oxide and sulphide are in contact at high temperature, it was determined to introduce a definite quantity of copper oxide into slags and see if the fusion with matte would eliminate it. But it seems unlikely that any copper oxide formed in slags remain uncombined, so the experiments were extended to cover silicates as well.

The materials used in these experiments were (1) the Anaconda reverberatory slag already experimented with, (2) a matte carrying 37.98% Cu, (3) pure CuO, 79.9% Cu, (4) specimens from a siliceous chrysocolla are, 18.86% Cu—pure chrysocolla contains 36.1% Cu. The following charges were made up: (1) 100 grams of slag were mixed with five five grams of chrysocolla ore, and fused over five grams of matte. (2) 100 grams of slag were mixed with five grams of chrysocolla ore and five grams of matte, and fused. (3) 100 grams of slag were mixed with one gram of copper oxide and fused over five grams of matte. (4) 100 grams of slag were mixed with one gram of copper oxide and five grams of matte, and fused.

All these charges were made up in fireclay assay crucibles and fused together in a gas furnace, out of contact with the flames. The temperature was raised slowly to about 1350° C., being over 1200° C. for an hour. At the end of that time the gas was turned off, the temperature falling rapidly, and the crucibles were removed only when cold. After the crucibles were broken the pieces of slag were separated carefully from the matte and heated to about 1000° C., when they were dropped into cold water. After drying they were bucked and assayed. Hydrofluoric acid was still necessary for their complete decomposition, so the copper oxide could not be accurately determined. However, all the slags were treated 8 hr. at 70° C. with H_2SO_4 (1:20) and were mainly, though not entirely, decomposed. Hence actual copper oxide is higher than reported in Table 7.

TABLE 7. ACTION OF MATTE ON COPPER OXIDE AND SILICATE

	Matte	Slag			
Exp. No.	% Cu	Total Cu	Oxide Cu	Normal Cu (Fig. 12)	Excess of Normal
1	49.4	0.505	0.325	0.353	0.152
2	61.2	0.505	0.270	0.380	0.125
3	51.2	0.480	0.300	0.356	0.124
4	60.0	0.420	0.270	0.377	0.043

All the mattes are much higher than those charged, and especially those that were mixed with the slag and copper oxide or silicate. These two experiments also show lower copper oxide in the slag, and a smaller excess over the normal amount. But the point which the four experiments seem to establish fairly clearly is that the presence of copper sulphide in molten furnace products does not prove the absence of either copper oxide or silicate. They also indicate that the silicate is reduced with more difficulty than the oxide, and that if either of them be formed in excessive quantity it will result in a slag with more than the normal amount of copper.

(To Be Concluded)

Explosives Produced in the United States in 1914

The production of explosives, excluding the amount exported, in the United States during 1914, according to figures that the Bureau of Mines received from manufacturers, was 450,251,489 lb., as compared with 500,015,845 lb. in 1913 and 489,393,131 lb. in 1912.

The production for 1914 is segregated as follows: Black powder, 206,099,700 lb.; "high" explosives other than permissible explosives, 218,453,971 lb.; and permissible explosives, 25,697,818 lb. These figures represent a decrease of 23,839,831 lb. of black powder, 23,932,573 lb. of high explosives and 1,987,952 lb. of permissible explosives, as compared with figures for 1913.

Current Japanese Metal Outputs

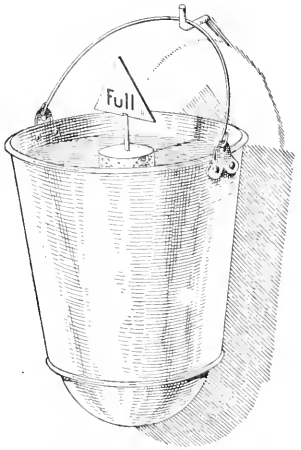
According to the Department of Agriculture and Commerce of Japan, the production of the principal mines and metals for the four months, January to April, 1915, inclusive, was: Gold, 2493 kg.; silver, 50,308 kg.; copper, 21,085 metric tons; iron, 16,011 metric tons; coal, 6,161,300 metric tons; petroleum, 151,687 hectoliters; sulphur, 16,469 metric tons. Coal, iron and sulphur show decreases; the rest show increases. The copper exports of Japan for the first four months of 1915 were 19,820 metric tons, as against 16,166 in the same period of 1914 and 13,824 in 1913.

Details of Practical Mining

A Fire-Bucket Float

. The accompanying illustration shows an ordinary fire bucket equipped with a simple and convenient contrivance for showing the amount of water in the bucket. The device consists of a cork or metallic float with a stiff wire spindle attached to it, on the top of which is fastened a triangular piece of sheet tin or aluminum, painted and lettered in colors that will contrast with the surroundings.

This saves the watchman from climbing on workbenches, up posts or the sides of the walls to see if the



FIRE BUCKET WITH SAFETY FLOAT

water buckets are full as required by the Insurance Associations.

When the bucket is full, the sign is visible for a considerable distance, but when the water has evaporated so that the bucket is only partly filled, the float disappears below the rim. These floats would also be an aid to the insurance inspectors when they visit plants where they have been adopted.—C. D. Parkhurst, in *American Machinist,* July 22, 1915.

Taking the Diamond Out of a Raise

By Frank S. Crawford*

In a four- or six-post raise the sets often become so out of shape as to look, in plan, like a diamond. To remedy this, put a level on the tops of the posts and it will be found that one or more of them are lower than the others. This results in their being drawn together, and the caps or girts are not level. Ascertain which posts are low and place a shim on the tenon of each so as to raise them to the height of the other posts, when placing the next set of timber. If it is too much to raise them in just one set, make them up in two sets. A shim is a piece of blocking or wedge cut to fit the mortise.

With the tops of the posts level, the caps and girts will be level; and with posts plumb, the sets will be square.

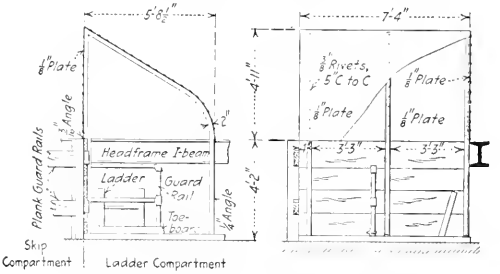
Cover for Shaft Ladderway

By D. E. Charlton*

The sketch shows a substantial covering for a shaft ladderway, which serves as a protection to the men ascending and decending the ladders and which is being used at some of the mines on the Mesabi Range. While not so elaborate or expensive as some, it is giving good satisfaction.

The framework consists of three V-shaped standards made of ¼-in. angle iron, 2 in. wide. These are made with a welded joint at the apex forming the V, and on the bases the metal is pounded over so that it forms a flange through which a bolt fastens the frame to the planks covering the ladder compartment of the shaft. The shape is shown in the end view, and in the side view



SAFETY COVER FOR SHAFT LADDERWAY

the two upright standards on the right, in part section, reveal the method of fastening.

The covering is made of ⅛-in. plate riveted to the standards with ⅜-in. rivets on 5-in. centers. This covering extends from the planking on the shaft side to the apex and thence down to the I-beam, as shown in the end view. This forms the roof, and it will be seen that such a shape has an advantage over the semi-circular or dome-shaped roof, as any material striking it will be deflected from the shaft rather than into it. With the semicircular type a certain portion of the material would fall into the shaft. The end opposite the entrance is also covered with plate, which is riveted to the last standard. The sketch also shows the guard rail and toe board in use.

A Dirt Strainer made of a layer of muslin backed by coarse wire screen over the mouth of a compressor-intake will add to the life of the machine.

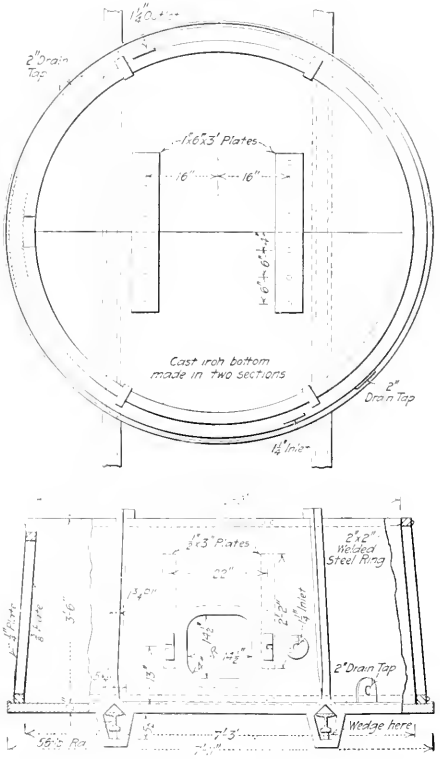
*Mechanical engineer, Virginia, Minn.

Details of Milling and Smelting

Granby Tapered Settler

By Frank E. Lathe*

The settling of furnace slag has received much attention at the works of the Granby Consolidated Mining, Smelting & Power Co., at Grand Forks, B. C. After experimenting with settlers of different sizes and shapes, the company is now adopting as its standard small



PLAN AND ELEVATION OF GRANBY SETTLER

tapered settlers arranged in a series of at least three, the slag cascading from one to the next.

The settler is 3 ft. 6 in. high and has an inside diameter at the bottom of 5 ft. 3 in. and at the top of 6 ft. 9 in. It rests on a cast-iron bottom plate 5 ft. 11 in. in diameter, made in two sections. The settler shell is held in place on the cast-iron base by the mild-steel tie-hooks, wedged over 56-lb. rails placed under the base-plate. The inside plates of the settler shell are of 3/8-in. steel and the outside plates of 1/4 in., a 2-in. water space being provided. The tapping block consists of two small water jackets which fit together, leaving a 3½-in. circular opening. Asbestos is packed around these jackets and further protection is afforded by 3/8-in. asbestos board placed between them and the brick lining.

Matte is tapped regularly from the first settler, and from the other settlers when it has accumulated to a depth of from 4 to 6 in. The advantage of the tapered form is that when the settler becomes partly filled with "metallics," which are usually formed under the conditions of siliceous slag and high coke, the shell may be lifted off the base and the sow disposed of without difficulty.

*Chief chemist, Granby Consolidated Mining, Smelting & Power Co., Ltd., Grand Forks, B. C., Canada.

Electric Precipitate-Melting Furnace*

The gold precipitate from the zinc-dust presses in the cyanide plant of the Alaska-Treadwell Gold Mining Co., Treadwell, Alaska, is treated by the lead-smelting method. About 3 or 4 tons of this precipitate is produced monthly, having a gold assay value of $40,000 to $60,000 per ton.

An electric furnace was constructed from an old steel acid drum by cutting off the top and introducing a cable, made from strands of bare copper wire, through the bottom and spreading the strands out fan-shaped on the inside of the drum.

Powdered graphite, obtained by grinding up old crucibles, mixed with 10% of cement was tamped wet into the bottom of the drum around and completely covering the copper wires. The graphite was carried up to the bottom of the furnace and acted as the lower electrode. The sides were built up of ordinary firebrick forming a melting chamber 14 in. diameter by 20 in. high.

The upper electrodes, of graphite or other carbon, are 3 in. diameter and 40 in. long, with joints enabling new electrodes to be connected without shutting down or wasting stubs. A screw feed was arranged for raising and lowering the upper electrode.

The cover for the furnace had three openings, one for feeding the charge, one for the escape of gases and one in the center for the introduction of the electrode. It was later found more practical to enlarge this center opening to 6 in. diameter to allow of a central feeding of the charge around the electrode.

The furnace is operated on the lighting circuit through a 50-kw. transformer, 60 cycles, 110 volts. Later a water rheostat was constructed to lower the voltage for use when starting the furnaces, or when there was a bath of metal in the bottom of the furnace.

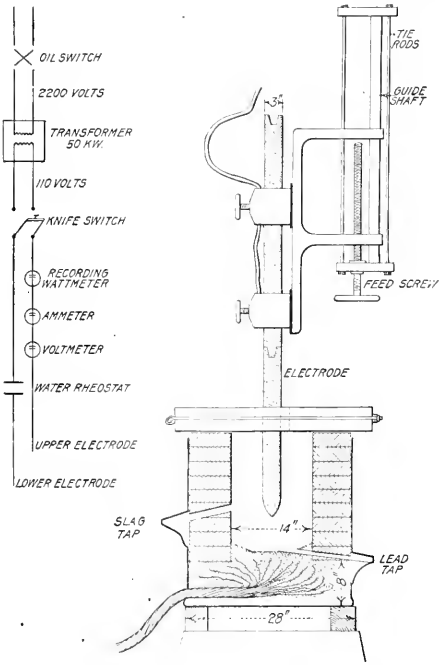
The material to be treated in the furnace is mixed in the following proportions: Refinery byproducts, 100 lb.; old reverberatory hearths, containing 60% CaO, 20 lb.;

*Excerpts from an article by W. P. Lass to be presented at the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

litharge, 20 lb.; coke, 2 lb.; scrap iron, 3 lb. About 160 lb. of the mixture is added for a charge. Coke is added to the charge as a reducing agent, only a quantity sufficient to throw down the lead being used.

The charge is introduced into the top of the furnace through the central opening around the electrode without removing the slab cover. In starting, it is operated as an arc furnace, until thoroughly hot, when the charge, consisting of slag, brick dust, etc., is added, the electrodes being raised as the load in amperes increases, until the entire chamber is filled with the charge and the upper electrode extends almost a foot into the melt. As the charge continues to melt the electrode is moved down or up, keeping the amperage reading as nearly constant as possible.

At this stage the furnace is no longer operating as a simple arc furnace, but has automatically transformed itself into a resistance type of furnace, the semifluid or molten charge acting as the resistance, the current passing



ELECTRIC FURNACE FOR PRECIPITATE MELTING

from one electrode through the center of the charge to the other.

After the charge is in quiet fusion the power is turned off and the charge allowed to settle for 15 min. before tapping the slag. This allows the lead to settle out, the furnace acting as a forehearth. In operation, the molten lead and slag are tapped, as in the blast furnace. If the lead freezes, it is melted by diverting current from the upper electrode and letting it pass through the lead, the tapping rod playing as an arc on the side of the furnace or into the lead tap.

Both graphite and gas-carbon electrodes are used, the former costing $2.95 each and the latter $1.20. Power cost is less than 1c. per kilowatt-hour. The labor required for the operation of the furnace, including the work of charging and tapping, is one-half one man's time, when melting 1 ton in 24 hr.

The advantages of the electric furnace compared to the blast furnace for melting high-grade gold slags are: A saving in mechanical loss of gold in flue dust, because

OPERATING DATA

Total running time	128 hr. 40 min.
Average weight of charge added	160.5
Average fusion time of charge	2 hr. 25 min.
Total number of charges	53
Graphite electrodes used	1 per 24 hr.
Total power for 128 hr. 40 min., kw.-hr.	4410
Power used per hour, kw.	34.50
Power used per pound of material fed, kw.-hr.	0.52
Power used per ton of material fed, kw.hr.	1044.0
Acheson graphite used per hour, ft.	0.15
Material melted per hour, lb.	67.7
Material melted for 24 hr., lb.	1625.0

the melting is done in a quiet neutral atmosphere instead of in a rising blast of air; the obtaining of a lower grade slag, free from shot, by reason of the quieter melting action and the higher temperature obtainable, making a more fluid slag; the nicety of regulation of the melting temperature, and the benefit to the general health of the operating force.

Sampling Lead Bullion

At the Ohio & Colorado smelting works at Salida, Colo., the base bullion was originally sampled by taking a dip sample from the lead well, which was not satisfactory, says F. D. Weeks.[1] The present management built drossing kettles in which the bullion is stirred by compressed air, skimmed into a Howard press, stirred by hand and siphoned out into bars for shipment, after sampling by dipping "gum-drops," approximating ½ assay-ton in weight.

For some time the results were unsatisfactory. Although the copper had been reduced to 0.06%, the bullion had a dirty appearance, and "gum-drops" of the same dip would not check with each other, especially as to gold content. Consultation with men versed in the subject did not help. A remedy was finally found when the temperatures were determined by a pyrometer and the difficulties overcome by the following procedure: Take off heavy dross at 900° F.; blow until temperature reaches 680° F., skimming from time to time; raise the heat to 720° F. for sampling, and mold at 800° F. Since this method was adopted, there has been little trouble.

Ridge Roasting Furnace

H. M. Ridge, of London, has been granted a patent (U. S. pat. 1,143,438) for a multiple-hearth roasting furnace which will permit a certain part of the furnace to be put out of action without interfering with the working of the other part. This is accomplished by means of closable discharge openings in the hearths so arranged that while in normal working the ore may traverse the entire length of each hearth in succession, but should it be desired to cut out part of the furnace, the rabble shafts of that part are stopped and, without other alteration than the opening or closing of certain discharge outlets, the ore may be caused to traverse in succession the several hearths of the other part of the furnace. A variety of furnace constructions is covered, such as where the rabbles do not overlap, and vice versa.

[1]Excerpt from a paper entitled "The Salida Smelter," to be read at the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

Company Reports

Tonopah Belmont Mine

Report of the Tonopah Belmont Mining Co. for the year ended Feb. 28, 1915, shows that the ore reserves consist of 226,921 tons of positive ore, 6355 tons of probable ore, and 61,808 tons of possible ore, a total in reserve of 295,084 tons. The year's development has proven the ores of the Belmont vein to be cut off by the Mizpah fault at the bottom and to terminate to the eastward, above the fifteenth level, against the glassy trachyte. Moreover, the ores of this vein, which almost entirely through the areas hitherto mined have been above the normal grade, have not continued of high grade to the lower and eastern limits of the deposit, as was expected, but instead diminish in tenor generally downward and to the east.

On the other hand, the development of the mine apart from the Belmont vein has been encouraging. Most notable was the discovery and exploitation of the Western vein, and the development of the Favorite vein on the 900-ft. level, where an orebody of good width and excellent grade is being proven.

The amount hoisted was 228,328 wet tons. From this 42,628 wet tons, or 18.67%, was thrown out as waste, and the remaining 185,700 tons—or 181,370 dry tons—delivered to the mill. The average value per ton was $16.747, made up of 0.234 oz. gold and 22.34 oz. silver. The total operating costs were $7.268 per ton, and the losses in mill tailings and in sales of concentrates were $1.274 per ton, making the total cost and losses $8.542 per ton. The profits per ton, exclusive of miscellaneous earnings, were $8.205, and the percentage of profits for Tonopah operations, 48.99.

MINING COSTS AT THE TONOPAH BELMONT MINE

	Amount	Per Ton
Development, direct:		
Miners	$74,602.03	$0.411
Muckers and trammers	37,181.14	.205
Timbermen and helpers	12,189.04	.067
Stoping, direct:		
Miners	91,186.88	.503
Shovelers	51,278.73	.283
Trammers	39,162.22	.216
Timbermen and helpers	126,647.39	.698
Filling	8,317.14	.049
Piston drills, repairs and maintenance	4,961.09	.027
Stoping drills, repairs and maintenance	6,967.43	.038
Steel and sharpening	13,810.70	.076
Explosives	81,128.93	.447
Hoisting to surface	36,750.25	.202
Auxiliary hoisting	149.47	.000
Ore sorting and loading	17,642.80	.097
Sampling and assaying	7,891.73	.044
Surveying	7,025.15	.039
Supt. and shift bosses	17,862.21	.098
Mine office	14,216.72	.078
Surface and plant	17,157.30	.095
Lighting	7,867.04	.043
Heating	9,663.19	.053
Drayage	3,421.95	.019
Maintenance and repairs, buildings	1,035.11	.006
Maintenance machinery and tools, shop tools	880.06	.005
Maintenance pipe lines and tanks	2,275.13	.013
Maintenance railroad spur	1,713.89	.009
Pumping	16,514.58	.090
Ventilation	5,918.05	.033
Total direct cost, mining	$715,417.65	$3.944
Administration	10,232.69	.056
Taxes and insurance	15,616.65	.086
Legal and traveling	2,556.85	.014
Bullion tax	23,500.00	.130
Depreciation	15,028.44	.083
Total indirect cost, mining	$66,934.63	$0.369
Total operating costs	782,352.28	4.313

During the year the property produced 3,714,861.91 fine ounces of silver. The average price received for the silver sold, 2,008,763 oz., was 55.16c. The highest price received was 59.125c. and the lowest price 48.25c. For the silver sold—combined with the silver in storage, which is carried at 50c. per oz.—the average price for the year is 52.84c. A gross tonnage of 228,328 tons of crude ore, of an average value about $13.61, was mined during the year. Of this, the Belmont vein furnished 77,730 tons, the Shaft vein furnished 63,887 tons, the Occidental vein 12,011 tons, the Favorite vein 18,883 tons, other veins making up the remainder.

There were 24,630 ft. of development work performed during the year, at a cost of $72.46 per ft. The drifting cost was $7.592 per ft.; the crosscutting cost, $6.228 per ft., and the raising cost, $8.326 per ft. The high cost of raising was due to the fact that there were heavy timbers used in the raises and many were on flat veins.

The items of labor, supplies and power, comprising the direct mining cost per ton, were $2.423, $1.231 and $0.29. The development cost was $1.168 per ton and the stoping costs were $2.777 per ton. The total direct mining cost was $3.944, while the indirect cost was $0.369 per ton. The accompanying table shows the operating expenses per ton and in total for the year.

*

Seoul Mining Co.'s Operations

The report of the Seoul Mining Co., Holkol, Chosen, for 1914 shows a total ore reserve of 1,206,133 tons having a gross value of $15,914,375. The ore is complex, containing gold and copper, and it is noteworthy that in the present estimate copper is calculated at only 12c. per lb. The usual dividend of 50% on the capital stock was paid during the year.

The Suan mine has a total ore reserve of 236,536 tons, containing $9.13 in gold, 1.12% copper and 1.7 lb. of bismuth, or a total value of $12.86 per ton. In this estimate copper is calculated at 12c. per lb., and bismuth at 60c. per lb. The mill treated 74,450 tons of ore during the year, after discarding 7922 tons as waste. The actual running time of the mill was 338 days, 15½ hr., or 92.77% of the possible time. The stamp duty per day was 5.5 tons. After a series of tests the flotation process was installed for treating the pulp from the tube mills. This was put in operation toward the end of April, and the copper extraction was increased from 20% to about 75% and gold extraction from 82% to about 88%. The total yield from the mill was $701,-181.75.

At the Tul Mi Chung mine the total ore reserve is 963,500 tons, containing $8.14 in gold, 1.59% in copper and 0.8 oz. of silver per ton. Further details of this mine and its milling plant are given on p. 275 of this issue.

The power station at Pyeng Yang, the transmission lines and motor installation were not completed until

the end of the year on account of high floods which delayed the transportation of material and wiped away a section of the transmission line.

Early in 1915 the change from steam to electric motive power was effected at the Suan mine and mill, and the plant is now working satisfactorily. The operating costs per ton are shown in the accompanying table.

OPERATING COSTS OF THE SEOUL MINING CO.

Mining	$1 38
Starting and transporting ore to mill	10
Milling	1 00
Concentrating	49
Office expenses	24
Agencies	09
General expenses	09
Insurance	02
Freight and transportation	04
Messengers and police	04
Livestock	03
Surveying	02
Traveling expenses	04
Cables and telegrams	04
Bullion expenses	04
President's and secretary's office	13
Legal	01
Hospital	10
Total	$3.90

During the year 36 tons of high-grade ore, valued at $2520, was shipped to England. Since the installation of the flotation process at the Suan mill it is not likely that any more high-grade ore consignments will be made from the Suan mine. The average receipts per ton from all ores were $9.44, the operating costs $3.90, and the profit per ton $5.54. Operations are continuing and ore reserves are being increased regularly.

Round Mountain Mining Co.

The report of the Round Mountain Mining Co., Round Mountain, Nev., for two years ended Mar. 31, 1915, shows that in July, 1914, the capital stock of the company was increased from 1,000,000 shares to 1,500,000 shares of $1 each. The total outstanding shares at the end of the year amounted to 1,188,019, leaving a balance of 311,981 in the treasury. The land holdings of the company now approximate 800 acres, of which 241.9 acres are patented.

For the year ended Mar. 31, 1914, the mines produced 57,187 tons of ore at an average value of $5.28 per ton. Tailings losses were 73.5c. per ton, leaving a net recovery of $4.55 per ton, or 86.1% of the value contained in the ore. Net operating profits were $13,357.

During the year ended Mar. 31, 1915, the mines produced 48,230 tons having an average value of $6.57. Tailings losses were 87c. per ton, leaving a net recovery of $5.70, or 86.8% of the total metal contents. Net operating profits were $44,931.

Development work for the year ended Mar. 31, 1915, amounted to 4707 ft. at an average cost of $8.40 per ft., compared with 4173 ft. at an average cost of $7.27 during the previous year.

Following placer mining operations conducted by lessees from 1906 to 1915, resulting in a gross production of $339,589 from hydraulicking 218,818 cu.yd. of dirt, having an average value of $1.55 per cu.yd., the company is to undertake these operations itself. An estimate of hydraulic ground tributary to the main tailrace is estimated to contain 1,508,445 cu.yd. of an average gross value of 81. This estimate covers 66,776 acres with an average depth of 14 ft. No estimate has yet been made of other placer ground owned by the company, some of which is 40 ft. or more to bedrock. To supply water for this work a pipe line is being constructed from Jett Cañon. The first section of this line from the intake in the cañon consists of 14,000 ft. of riveted steel dipped pipe, varying from 30 in. in diameter at the head to 15 in. The second section consists of 28,000 ft. of lap-welded steel pipe $\frac{1}{4}$ and $\frac{5}{16}$ in. thickness and 15 in. diameter; the third section is 3336 ft. of riveted steel pipe 15 in. diameter. To guard against freezing, this pipe will be laid 41 in. deep. Only 7550 ft. of this pipe will be slip-jointed, the remainder being fitted with bolted forged steel joints. As surveyed, the total length of the line is 45,336 ft., and the estimated cost of construction is $145,000. An ample water supply will be assured, and it is estimated that from 1000 to 1500 cu.yd. of dirt per day can be washed. Measurements of the flow indicate that the pipe line will operate to full capacity for at least from four to five months of the year.

Union Copper Land & Mining Co., Michigan, reports that the company had $1169 on hand on Jan. 1, 1915, and that since that date it has received a payment of $8960 on a contract for the sale of timber which was made in 1913. The company still owns 6366 acres of land.

New Baltic Copper Co., Houghton, Mich., for 1914 reports an income from interest, etc., of $500 and after expenditures amounting to $353.8, a balance of $869 in cash on hand. The management intends to resume exploration work, and to provide funds an assessment must be levied on the outstanding stock or a sale of some stock effected.

The Broken Hill Proprietary Co. now has its works at New Castle, N. S. W., in full operation. Up to May 15 the total output was 12,763 tons pig iron, 2652 tons of openhearth steel, 1551 tons blooms and 429 tons rails. Two openhearth furnaces are in operation. A considerable number of orders for billets, rails and structural steel are in hand.

Seven Troughs Coalition Mining Co., Seven Troughs, Nev., shows a net profit of $145,035 for 13 months ended Apr. 30, 1915, and dividend payments of $36,075. The company ended the year with $76,864 in cash on hand and in bank, $45,000 in notes receivable, and $1819 in accounts receivable. No statement is made in the report as to the amount of ore treated.

The Davis-Daly Copper Co., Butte, Mont., for the quarter ended Mar. 31, 1915, states that receipts were $6439 and disbursements $57,224. Expenditures consisted of $44,249 for development, $2613 for mining, $4128 for equipment, $3604 for general expenses and $2630 for Boston expenses. Shipments consisted of 1135 tons of ore, averaging 3.7% copper and 7.2 oz. of silver per ton. Development work amounted to 1663 feet.

New Arcadian Copper Co., Houghton, Mich., for 1914 reports a balance on hand Jan. 1, 1914 of $24,557, receipts amounting to $13,238 and expenditures of $27,364, leaving a balance of $10,431 in cash on hand at the end of the year. There was also $6606 of assessments to be collected. The shaft was sunk from the 750-ft. level to 900 ft. Development work consisted of 710 ft. of crosscutting and 795 ft. of drifting. Some ore was stoped for a test run which is to be made on the ore recently opened up.

Saint Mary's Mineral Land Co., Houghton, Mich., for 1914 reports total receipts amounting to $20,376, of which $11,400 was from the sale of wood and timber, $2810 from ground rents, $6101 from interests receipts and $65 from miscellaneous sources. All expenditures amounted to $129,349. The real property of the company consists of 93,032 acres of land and mineral rights to 14,112 additional acres. Its principal source of revenue is from a one-half interest in the Champion Copper Co., which paid no dividends last year.

New Idria Quicksilver Mining Co., California, for 1914 reports a loss of $45,010. A dividend of $10,000 was paid. Ore produced amounted to 62,578 tons, which furnished 6550 flasks of quicksilver. There were 12,367 ft. of development work performed. During the first eight months of the year the average price received for quicksilver was $76 per flask. For a short time after the war started it rose to $75, but steadily declined to $48, and the average price received was $41 per flask.

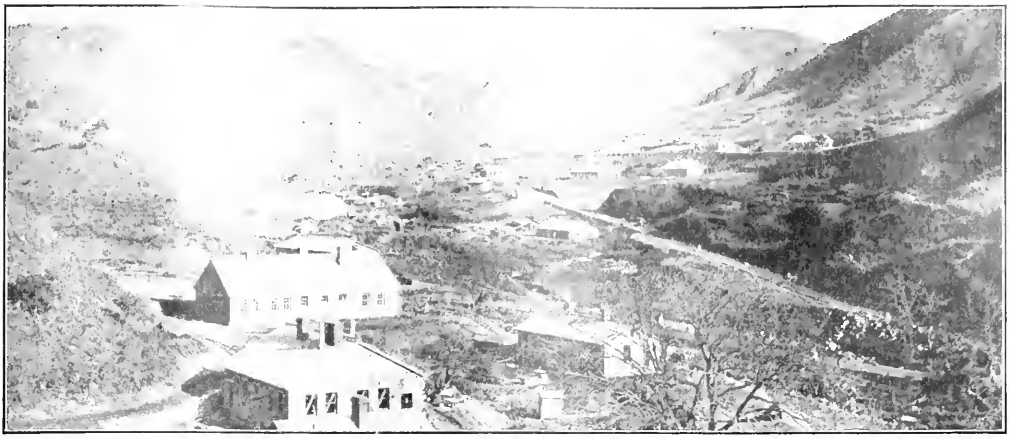
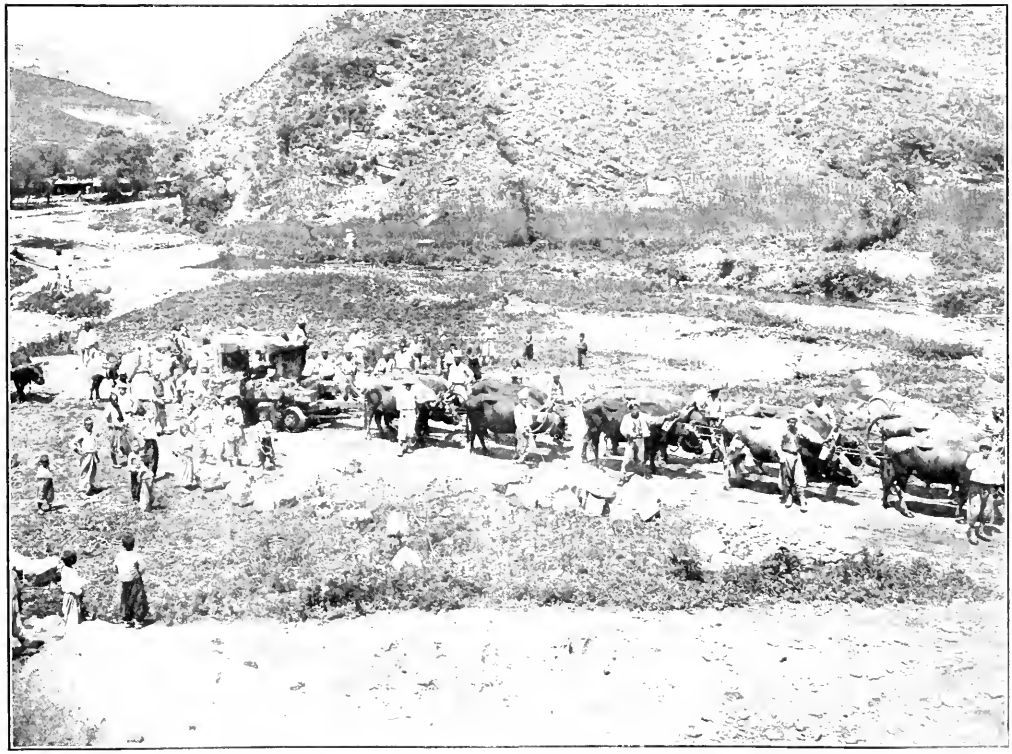
Upper view shows the Wis[illegible] mine, also formerly operated [illegible] great limestone pinnacles



GENERAL VIEW OF CAMP OF TUL MI CHUNG MINE, SUAN CONCESSION OF SEOUL MINING CO., CHOSEN

During 1914, $229,457 was expended on this mine, and the total capital expenditure to Jan. 1, 1915, was $358,648. There are over four miles of drifts, etc. Positive ore is given at 614,900 tons of a value of $7,796,546 and probable ore at 348,700 tons of a value of $4,108,009. The value of the positive ore is divided as follows: Gold, $5,189,756; silver, $245,960; copper, $2,360,830. Probable ore: Gold, $2,657,094; silver, $139,480; copper, $1,311,525. The assays are: Positive ore, Au, $8.44; Ag, 0.8 oz.; Cu, 1.60%. Probable ore, Au, $7.62; Ag, 0.8 oz.; Cu, 1.57%. The deepest level working on ore is the 300-ft., which is said to be in excellent condition and to give great promise.



TRANSPORTING HEAVY MACHINERY FOR THE SEOUL MINING CO., CHOSEN

A 30x18-in. rock breaker, weighing 9½ tons, hauled by a team of 28 bullocks, en route to the Tul Mi Chung mill. The mill will be about 3000 ft. from the portal of the main adit. The first unit of the plant will have a capacity of 100 tons per day, and should have begun operating in July. Grading was completed in April. It is expected that the mill will ultimately will treat 400 tons per day. The Tul Mi Chung mine is considered by its owners to be the premier mine of Chosen, and is unique in that it is the only profitable mine in that territory in which no work by the natives was going on at the time it was discovered.

Gold Precipitation on Paper

By Douglas Lay*

SYNOPSIS—Former methods of electrolytic precipitation have had the disadvantage of a costly separating system for recovering precious metals. This description is of a method of using paper, which can be burned, leaving no impurities in the bullion.

Apart from any other inherent advantages which electrolytic precipitation may possess over the chemical systems, the former method merits attention at the present time on account of the high price of zinc. Hitherto electrolytic precipitation appears to have received the cold shoulder, doubtless because of the many extravagant claims made on its behalf which have not been realized in practice.

Weakness of Former Electrolytic Processes

In my experience, electrolytic precipitation on sheet-lead cathodes proved highly satisfactory, precipitation being just as complete as when zinc was employed. But electrolytic precipitation on a metallic cathode and chemical precipitation by means of either filiform zinc, zinc dust or aluminum, all involve, subsequent to precipitation, separation of the precipitated precious metal from the lead, zinc or aluminum, as the case may be, before the precious metal is recovered in the form of bullion.

The method of electrolytic precipitation on paper cathodes, herein described, has been evolved with the object of eliminating as far as possible the separation of the precipitate from the precipitant. If precipitation on paper cathodes proves to be satisfactory—and experimental work gives ground for high hopes—then it would appear to be a step in advance of precipitation on a metal, owing to the simple operation required after precipitation to yield the precious metal in the form of bullion.

Before proceeding to a detailed description of the method, it is well to say that I am far from laying claim to any originality in the matter of making a nonconductor, such as paper, a conductor of electricity. The art of making nonconductors conductors has been known for more than half a century. Originality, if originality there be, lies in the manner of application of this known art to the cyanide process, that is, in precipitation on a combustible cathode.

Further, no claim is made that this method has yet emerged beyond the experimental stage, inasmuch as time and opportunity have not permitted an actual cleanup on a full commercial scale. At the same time, all experimental work herein described was carried on with actual mill solutions and in an electrodeposition tank of full commercial size, containing 3500 sq.ft. of sheet-lead cathode surface. Opportunity only permitted of the trial for 30 days of a limited number of paper cathodes. These latter were hung from the negative crossbar, side by side with lead cathodes, and appeared to receive a deposit of precious metal just as readily as the lead cathodes.

Briefly, the process consists in the electrolysis of the clear cyanide solution, and the precipitation of the precious metals on paper cathodes. Whenever it is desired to make a cleanup, incineration and melting of the cathodes will yield the precious metals in the form of bullion.

Preparation of Paper for Electrodeposition

Any paper of reasonable stoutness and having a smooth surface, such as the pages of the *Engineering and Mining Journal*, answers well. It is cut into strips of the required size, preferably not more than 2 or 3 in. in width. These strips are immersed momentarily in melted beeswax. Before the wax has solidified, the sheets are dipped in flake graphite (not plumbago), which is thus made to adhere very firmly to the paper. When the latter has cooled, more graphite is rubbed on the surface of the paper until the latter appears highly polished. The function of the beeswax is twofold—it not only renders the paper waterproof, but also serves as a bed for the graphite. It is advantageous but not absolutely necessary to dip the sheets, prepared as described in alcohol and again in water, to remove any air adhering to the surface. The cathode is now ready for immersion in the electrodeposition tank. Electric connection is established with the negative main in the following manner: Each cathode strip is clamped at the upper edge between two strips of sheet copper about ¾ in. wide, by means of small clips (ordinary tie clips answer very well). A copper hook soldered to one of the copper strips suspends the cathode from the negative crossbar.

Details of the Electrodeposition Tank

As has already been mentioned, the great majority of cathodes employed were of sheet lead, opportunity not permitting of a trial of more than a limited number of paper cathodes. The tank had a total cathode area of 3500 sq.ft., giving it a capacity of 2 tons of solution per hr., that is to say, solution flowing through it at this rate was entirely robbed of its precious-metal contents. The tank was constructed of 3-in. plank and was 35 ft. long, 5 ft. wide, 3 ft. deep, all these being dimensions in the clear.

Anodes were of No. 10 sheet iron, 5 ft. 1 in. long by 2 ft. 8 in. deep, and were fitted into saw cuts in the sides and bottom of the tank. To promote thorough circulation and ionization alternate anodes were raised 2 in. above the level of the solution, the remaining anodes being fitted into the bottom of the tank. Each alternate pair of anodes, therefore, formed a water-tight compartment, consequently the whole of the solution was caused to flow over one anode and under the next. The distance between anodes was 3 in. Anodes were enclosed in cheesecloth to prevent chance of short circuiting. Electrodes were connected in multiple. Anode connections below the level of the solution are gradually eaten away. These connections were thoroughly insulated in the following manner: The positive main to which each

*Mining engineer, 14 Westbourne Road, Forest Hill, London, S. E., England.

of the anodes was connected was carried along the top of one side of the tank in a plow-way. The anodes projected ½ in. into the sides of the tank. From the bottom of the plow-way, ½-in. holes were drilled to the tops of the anodes, electrical connection being effected by filling these holes with molten lead after the anodes and positive main were in place. On top of this side of the tank was tacked a strip of wood, 3 in. wide, running the entire length of the tank. On this strip rested the ends of the cross-bars, which carried the cathodes. The other ends of the cross-bars rested on the negative main which passed along the other side of the tank. Cross-bars were placed midway between anodes so that the distance between anode and cathode was 1½ in. Cathode crossbars were of ⅜-in. round common iron.

The manner of connecting the paper cathodes to the negative crossbars has already been described.

The action of the electric current is gradually to oxidize the anodes. In this particular case the anodes were of iron and the anode product consisted mainly of floating flocculent hydrated ferric oxide which accumulated in the anode compartments. The removal of this floating anode product was readily effected by the following device: Above the level of those anodes which projected 2 in. above the level of the solution, the tank had at its outlet end an overflow lip. Below this lip at the normal level of the solution was the normal outlet pipe. By closing a valve on this latter pipe the level of the solution could be raised above the tops of the projecting anodes, causing a direct flow throughout the tank and the rapid and complete removal of the floating anode product over the flow lip into a sump tank. The only labor involved in this operation was the opening and closing of a valve. This operation was found necessary only once in every 24 hr. It is to be noted that the anode product always carries high precious-metal values, which however are loosely held, and which rapidly pass into solution again in the sump tank.

Efficient sampling of the solution heads and tails was effected by pet-cocks at the inlet and outlet ends of the tank. These pet-cocks were kept open slightly so that there was a constant drip into a vessel placed to receive the sample for assay.

A weak current was used, the current density being 0.02 amp. per sq.ft. of cathode surface, and the pressure from 3 to 4 volts.

Noteworthy Features of the System

The following appeared to the writer to be advantageous features: The small amount of attention required; the ease and cheapness with which a cleanup could be made as compared with other methods of precipitation, incineration and melting of the cathodes yielding the precious metals in the form of bullion; the continuous nature of the process. A cleanup entails no stoppage of operations whatever. Cathode sheets may be removed as often as desired and replaced by new ones without switching off the current. The precipitated precious metals adhere firmly to the cathode. There is no danger of mechanical loss from particles dropping off. At first consideration it might be thought that a paper cathode would rot after lengthy immersion in the solution. The reverse of this takes place. As the deposit of precious metal increases, the paper cathode becomes more and more metallic in appearance and properties. After 30 days' immersion, paper cathodes were found to ring, when tapped with a piece of metal. There is a small consumption of electric power and the cost of precipitation is low.

Antimony Production of the World

In *Engineering* for July 9 there was a very good summary of the world's antimony production, excerpts from which, together with some comments, constitute the following:

During the autumn of 1914 the war demand developed. Russia bought in Great Britain, Japan and the United States, the total Russian demand being in excess of 2500 tons. At least an equal quantity was purchased on behalf of other nations.

Metallurgy of Antimony

The process of extracting antimony from the ore is a simple one, but there are several processes employed. The crude commercial antimony is the ore separated from the associated earthy gangue; this operation is performed by simple fusion. From this there are several means of obtaining the regulus of antimony. The raw antimony, whether obtained direct from the ore or from the purified sulphide, must be calcined, in order to separate such impurities as arsenic and sulphur. In the direct process of obtaining antimony, the ore is smelted with some alkaline slag and old scrap iron. When this combination has completely fused, it is poured into conically shaped molds, and this mixture, after cooling, consists of impure antimony and sulphide of iron. There are several methods available for purifying the regulus; one of the simplest is to charge each of a number of crucibles with this regulus along with soda, common salt and pure oxidized antimony ore. When sufficient heat has been applied, the foreign impurities, or metals, become oxidized and scorified, and the antimony is thus obtained. It is a bright, silver gray metal, brittle, and readily pulverized.

The roasting of antimony is very similar to the roasting of lead matte; until recently it was roasted either in hand reverberatory furnaces or in single-hearth furnaces. The essential point of the furnace is the absolute control of temperatures. In roasting antimony, should the temperature rise to about 350° C. in the early stages of the roast, there is a tendency towards fusion; but later in the roast the temperature may be raised considerably beyond 350° C.; it is, in fact, quite possible to do so without any difficulty arising. The fusion takes place in the early part of the roast. The control of temperatures in improved furnaces enables the heat of the sulphur to be utilized when present. The older system of hand reverberatory furnaces entailed a large fuel consumption.

[The article does not refer to the modern process of antimony smelting, developed in France by Herrenschmidt, wherein the antimony is burned off in kilns, the oxide being collected in bag filters, and subsequently converted to metal by reducing smelting. This process gives a high extraction of metal and a product of excellent quality.]

World's Production of Antimony

Of the world's total output of antimony three-fourths of the ordinary 99% grade comes from China; the cost of production is lower than in any other country. No less

than 100 mining companies have been established, and eight smelteries have been erected, but they are not as yet all at work. The important companies are the Wah Chang Mining & Smelting Co., of Changsha, and the Pao Tai Mining & Smelting Co., of Wuchow. Antimony is not at present known to occur in northern China, the main source of supply is the western central region; the trade routes by means of which the mineral wealth of Central China reaches the coast are the Yangtse River, the Shanghai at the estuary, and the West River. The total exports exceed 12,000 tons of metal yearly, besides several thousand tons of ore, the main portion being shipped from Changsha and the smaller quantities from Yochow, Hankow, Wuchow and some other ports. Amoy is a district from which antimony may be exported in considerable quantities in the future.

Much of the Chinese output is shipped as crude ore, to be smelted and refined in Europe. Reliable returns for 1914 are not yet available; for recent years the Chinese exports have been as follows:

	1910, Tons	1911, Tons	1912, Tons	1913, Tons
Ore	5,665	6,700	2,020	4,250
Crude	6,535	6,875	13,310	12,820

[It may appropriately be added that a great deal of the Chinese antimony, especially that of the Wah Chang company is a high grade of metal, its analysis being superior to certain British brands which sell for higher prices. The Wah Chang company is under the direction of H. Y. Liang, who studied metallurgy in New York and London and gained experience in antimony smelting with Herrenschmidt in France. In his works the oxide-baghouse process is employed.]

Mexican Antimony Possibilities

There are both mines and smelteries in Mexico, one is in course of erection in San Luis Potosi; by the time mining and transportation conditions permit ore to be produced it will be ready for operation. The smeltery will have a capacity of 3000 tons per annum of refined antimony and will employ at least 150 men. The output is more likely to go to America than Europe. The ores to be worked up will be obtained from mines in Queretaro and San Luis Potosi. At present there is only one antimony smeltery working in Mexico, located at Wadley, a small station about 100 miles north of San Luis Potosi. The Wadley smeltery is not equipped for finishing the product, and its output has been exported to Great Britain for further refining. This smelter has worked for about 14 years, and has drawn a large part of its ore from the Catorce district.

The quantities of crude antimony and regulus sent from Mexico to Great Britain have been as follows:

	Tons		Tons
1910	2788	1912	3296
1911	3997	1913	2345

[A large deposit of antimony ore occurs in Mexico, about 9 miles north of Zimapan, on the upper slopes of the lower half of the great Moctezuma cañon. This is of lead-antimony ore and is known as "La Sirena." It was described by Dr. R. W. Raymond in the *Journal* of Jan. 2, 1915.]

French antimony, reduced both from native and imported ores, supplies the home demand, and before the declaration of war found a market in the United States. The output may be approximately estimated to be as follows:

	Tons		Tons
1910	4550	1912	5430
1911	4790	1913	5900

Canadian Production

In Canada there has been a small output of antimony from Nova Scotia; but no Canadian antimony has been sent to Great Britain since 1911, and then only in very small quantities.

A few years ago interesting and apparently important deposits were found in the northern portion of the Yukon territory. They are limited in their occurrence, so far as ascertained, to a small area 8 or 10 square miles in extent, known as Carbon and Chieftain Hills, about 33 miles above the point where the Wheaton River flows into Lake Bennett. The deposits are not more than 10 or 12 miles north of the sixtieth degree of latitude, forming the British Columbia-Yukon boundary. The deposits can be reached from Vancouver by steamer, then rail followed by road. The veins (of stibnite) vary in width from a few inches to 5 ft. The gangue material is generally quartz.

The other important antimony producing country is Australia, which exports from 1000 to 2000 tons of ore per annum to Great Britain. The production of Japan and Hungary has dwindled to insignificance. A small quantity of ore used to be exported annually from Turkey. The production of the United States—never large—has been trifling in recent years. The antimony smeltery at Chelsea, Staten Island, N. Y., has been idle for a long time. In England smelting and refining is carried on by seven important companies, the works being located one each in Runcorn, Newcastle-on-Tyne and St. Helens and four in London, with a branch in Patricroft, near Manchester.

Mineral Production of Peru

The mineral production of Peru for 1912 and 1913 has just been officially reported in the *Boletin* del Cuerpo de Ingenieros de Minas, No. 81, 1915, as follows:

Substance	Unit	1912	1913
Coal	Metric ton	278,927	273,945
Petroleum	Metric ton	233,600	276,147
Gold	Kilogram	1,435	1,429
Silver	Kilogram	324,352	299,132
Copper	Metric ton	26,970	27,778
Lead	Metric ton	4,050	3,927
Zinc ore	Metric ton	...	22
Vanadium ore	Metric ton	3,048	...
Bismuth (fine)	Kilogram	51,038	25,300
Tungsten ore	Metric ton	195	290
Mercury	Kilogram	400	460
Borax	Metric ton	1,674	2,001
Salt	Metric ton	23,292	24,433

The total value of the minerals produced in 1913 was 4,494,806 libras, as compared with 4,627,963 libras in 1912; 1 libra = $4.8665.

Gold-Bearing Conglomerates in the Philippines are reported to have been discovered along the Dekelan River near Iligan in Mindanao. This new gold field is not in the valley of the Cagayan River, on the other watershed of Mindanao, which has long been known to have gold and whose placers have been frequently described. The new field lies on the western slope of the range which separates the Cagayan Valley from Iligan Bay. The claims which have been located in this new field are situated about 11 miles northeast of the town of Iligan. Assays show from $1 to $25 per ton. The natives have for years obtained a small amount of gold from the gravel in the Dekelan River. The conglomerates are said to resemble those of the Witwatersrand.

Editorials

Recent Developments in the Mexican Situation

At last the policy of "watchful waiting" is to be abandoned and the affairs in Mexico are to be put in order in one way or another. Villa and Zapata appear to be tractable, but Carranza breathes defiance, and once more the *cientificos* are sticking up their heads. However, if we may believe the Washington dispatches all opposition is to be brushed aside and Uncle Sam, with the collaboration of the A B C powers—up to a certain point—is to do things. It is even foreseen that there may have to be armed intervention, but if it comes to that the A B C powers are going to let the United States do it alone.

But there has entered into the situation a new and troublesome consideration. Whatever government be set up in Mexico, it must have funds, which must be supplied by the bankers—that is, by the public. Yet where are the investors to be found who will put their money into an unguaranteed Mexican loan? The New Englander would as lief lend on the security of the codfish swimming in Massachusetts Bay. The idea of guaranteeing such a loan is a new one in Washington, which heretofore has been gleefully telling American investors that when they put their money in a foreign country they did so at their own risk.

⁂

Zinc Smelting in Great Britain

In view of the shortage of the spelter supply existing in Great Britain since the beginning of the war, along with the plethora of zinc-ore supply in Australia, the condition that causes us to marvel is the apparent absence of any general and serious effort to increase the zinc-smelting capacity of Great Britain. We have not been able to make a comprehensive survey of the present status of the British smelteries, but from reading of the British papers and our other information, we have not received the impression that anything energetic has been undertaken. We know, of course, that the capacity of Seaton-Carew is being increased, but on the other hand we heard but recently from another famous smeltery that its operator was still in the market for nothing but calamine ore, not yet possessing any blende-roasting furnaces, nor having any intention of building them.

The backwardness of British metallurgists in zinc smelting is one of the strange things of metallurgical history. The art of zinc smelting is supposed to have originated in India, from where it was carried to China, where zinc smelting is still done on a small scale by the primitive methods that date back hundreds of years. In the sixteenth century zinc was brought to Europe from China and the East Indies under the name of tutanego (whence the English term tutanegue), and it is likely that knowledge of it was obtained from that source at an earlier date. A few years previous to 1740 Dr. Isaac Lawson is said to have gone to China to study the method of zinc smelting there practiced, and to have brought the knowledge to England. Be that as it may, a patent for a process of distillation downward was granted to John Champion in 1739, and in 1740 he erected works at Bristol and actually began the manufacture of spelter, though his production was small, the chief part of what was used in Great Britain still being brought from India and China. For a good many years the process of making zinc at Champion's works was kept rigidly secret, but toward the end of the century the art was learned by Johann Ruhberg, who supposedly went to England for the purpose, returned to Upper Silesia, and in 1798, or 1799, made the first attempt at zinc smelting at Wessola in that province.

In spite of the great advances in the art that were made in Upper Silesia, in Rhenish Prussia and in Belgium, the British smelters continued to use their peculiar, clumsy and uneconomical furnace until the middle of the nineteenth century, and neither in that century nor later did they ever assume a leadership in this branch of metallurgy which they had introduced from the East. British supremacy passed away in this even earlier than it did in the metallurgy of copper and of lead. Only in the metallurgy of iron and steel has Great Britain held its own, and in this field the place of the country which gave the world both the Bessemer and the Thomas-Gilchrist processes is admittedly a fine one.

The reasons for the decadence of Great Britain in non-ferrous metallurgy would be an interesting subject for analysis and study. But of immediate concern is the question why its zinc smelters have failed to rise during the year of their country's need. They have the coal, they have the refractory material, and the ores could be brought to their seaports as well as they have been to those of the Continental countries. The reasons are perhaps to be looked for in the pernicious practices and baleful attitude of the British laboring man; and in the disinclination to take any chances involving the litigious Australian ore contracts.

⁂

New Jersey Iron Mines

Notwithstanding the depression in the iron trade last year, there has been considerable activity among the old iron mines of Morris County in New Jersey. The Mount Hope mines which are the oldest in the state, and, with two or three possible exceptions, the oldest in the United States, have been supplied with new machinery and made ready for a large output from the orebody uncovered a year or two ago. These mines have been supposed several times to be approaching the end of their life, but it is understood that the ore now in sight is greater in quantity than ever before and a large production is expected.

The Richard Mine at Wharton, now owned by the Thomas Iron Co., is to be further opened by a new concrete-lined shaft, equipped with new machinery, which

will reach a new ore lens and will enable the operators to increase the monthly production of ore to double the present production, or even more. Though not so old as the Mount Hope, the Richard has been worked for a number of years.

British Muddling Over New Jersey Zinc Co.

The obsession in Great Britain respecting the control of the metal markets of the world by the great metal merchandising concerns of Germany produces some humorous results. One of these was the birth of the myth that the zinc industry of the United States is controlled by German houses, who conspired to make the British pay an extortionate price for spelter. Another is that the pending investigation of an alleged spelter trust by the State of Missouri has something to do with this. The latest is the charge by London *Financial News* that the New Jersey Zinc Co. is the chief element in the alleged trust (the existence of which our contemporary takes for granted), that it connives and coöperates with the German houses, and that indeed itself is one of the enemies. "The view that it is of enemy character," says the *Financial News,* "is strengthened by the fact that one of its directors is, or was, August Heckscher, who was active in consolidating conflicting interests on the other side and so building up a big organization."

Here we have a lucid piece of reasoning. In the eyes of our London contemporary, there is a spelter trust in the United States, for the attorney-general of Missouri is assumed to say so; out of its own inner consciousness it evolves the idea that the aforesaid trust is controlled by Germans. The large number of concerns engaged in the American zinc business "does not by any means indicate competition," but "illustrates the measures taken by the Germans to secure control of a most lucrative, though complicated, business, while creating the appearance of freedom of trade." In other words, the organization of a large number of operating properties was to create a smoke to blind the eyes of the public. The New Jersey Zinc Co. is in the thing, of course, for is not August Heckscher a thoroughly Teutonic name?

This attack upon the New Jersey Zinc Co. led the London solicitors for that company to write to the *News* that neither it nor its subsidiaries are affiliated, directly or indirectly or by implication, with any other company. To this the *News* retorts that if the solicitors for the New Jersey Zinc Co. will assure it that their company is not a codefendant in the Missouri case, it may possibly believe that the New Jersey Zinc Co. is not to be numbered among the foes of England and the whole empire.

This is something like the famous inquiry addressed to a prisoner at the bar: "Have you ceased beating your wife? Answer me yes or no."

For the information of our contemporary in London, the *Journal* will assure it that the solicitors for the New Jersey Zinc Co. told the truth. Moreover, that the "nefarious Frankfort trio" is only moderately interested in the zinc industry of America; that it was stupidity in buying that put the price for zinc up to £100 per ton; that the State of Missouri is not proceeding against the zinc smelters on the charge that they are combined in a trust, but simply is conducting an inquiry to find out if such a trust exists; and that the aforesaid inquiry was instigated not to hunt out the "nefarious Frankfort trio," but to satisfy the Joplin producers of zinc ore, who wailed that they were not getting a fair share of the high prices for spelter.

On Zinc Poisoning

In a discussion of occupational diseases in the *Journal of Industrial and Chemical Engineering* reference has been made to the form of zinc poisoning known as "spelter chills." Zinc smelters are less subject to metal poisoning than are lead smelters; so much less indeed that some persons are disposed to deny that zinc vapor is poisonous, attributing the trouble experienced by brassmakers to copper vapor alone.

H. W. Gillett appears, however, to have brushed aside that hypothesis in an effective manner. He cites the evidence of Lehman, who produced "spelter chills" in several persons, including himself, by the inhalation of fumes arising from c.p. zinc and found the symptoms to be identical with those of "brass shakes." He cites, moreover, the evidence that "spelter chills" existed at Lasalle, Ill., among the smelters in 1910.

Mr. Gillett makes it rather uncomfortable for his opponents when he suggests that they emulate Lehman, by heating a pound or so of zinc to 920° C. in a small unventilated room and inhaling the fumes for a few minutes—pointing out that if their ideas be correct there should be no ill after-effects.

The obsession of the London market for standard copper still obtains, especially since it has become an open market again by the lifting of the embargo against exports. Its effect upon our copper market is rather upon the imagination of copper buyers than it is upon the producers, while its influence upon the stock market is not inconsiderable. All these things interlock.

Thus, certain persons surmise, or have definite knowledge, that there is going to be a demand for copper for ammunition contracts, let us say, which is likely to stimulate a rise in the price for the metal. Those possessing such knowledge may buy copper stocks and produce a rise in them before anything is done in the metal. Then comes a decline in the London market for standard copper, and the prospective buyers, affected sentimentally, hold off, copper stocks go off and pessimism prevails.

But of course the copper will be bought later if it be needed and the upward movement in the metal will be started, though perhaps from a lower level than was hoped in the first place. Naturally, in the long run the price for copper is determined by demand and supply, and by nothing else.

The question whether the time has not come when the barrel as a unit for portland cement may be dropped and the bag substituted in its place is raised by *Engineering News.* Its arguments in favor of the bag are rational, and the *Journal* unites with its contemporary in advocating the change, but why not have a bag of 100 lb. net instead of the existing standard of 94 lb. and obtain a unit that is easy of combination with other units?

BY THE WAY

The sluggishness of the copper stocks during the last three months has been a subject of wonder. The zinc and lead stocks have figured prominently among the "war brides." The copper stocks have been back among the wallflowers.

⁂

A fitting memorial to Barton Sewell, late president of the Braden Copper Co.—in which he took such an active interest in the later years of his life—has been created by a resolution of the directors of the company, "That one of the company's towns in Chile be hereafter named and called Sewell." In accordance with this resolution, Pope Yeatman gave instructions that the reduction-works town, formerly known as Molino, be changed to Sewell.

⁂

A German metallurgical manager, writing to a friend in this country recently, remarked that his works were necessarily running at a reduced rate owing to shortage of labor. However, he expected soon to receive a consignment of Russian prisoners which would enable him to get things going again on a good scale. We have previously made some remarks on the subject of captive labor, which appears to be rather an important factor in the industries of Germany at present.

⁂

In the *Saturday Evening Post* for July 31, 1915, Charles E. Van Loan describes Virginia City—one of the ghost cities of the West, he calls it. His account is far more accurate than is the common essay of this sort by the tenderfoot. Perhaps Mr. Van Loan is not a tenderfoot at all. Anyway his article is mighty interesting. Here is one of his stories:

> Not long ago a Japanese diplomat visited the West and in the course of his wanderings came to Virginia City. He was received with all courtesy—and when it comes to courtesy no state in the Union can give points to Nevada—and shown the various points of interest.
>
> "This," said the guide, "used to be the shaft of the old Con. Virginia. They took sixty-five millions out of that hole in the ground. . . . . Over there used to be the California—forty-seven millions. . . . . Here is where the old Mexican mine used to be. . . . . This is the Enterprise office. Mark Twain used to be a reporter on this paper." And so on.
>
> The visitor was very polite, but somewhat noncommittal. At the end of the afternoon the guide thought to prod him into a direct statement. "Well," said he, "what do you think of Virginia."
>
> "I think," said the Japanese, still politely, "that it is a very great used-to-be."

⁂

Ignorance, carelessness or haste often causes ludicrous blunders in the typing of reports and the printing of mining prospectuses. When one of the latter speaks of the "typographical" features of a mining property, a reader may be pardoned for entertaining the suspicion that the promoters are running a "printing press" mine. The inadvertent transposition of two letters in a report made "ore reserves" change to "ore reverses." This was unfortunate but true, as the company was unable to raise the desired cash to raise the ore to raise more cash to raise the spirits of the stockholders who were already in. In a letter which embodied what was in substance an offer to sell for money, marbles, chalk or promises, an enthusiastic tropical booster stated that he had 22 "gold placed" claims in the Republica de ——, which showed values running from 8c. to $00 per cubic yard; ideal either for dredging, hydraulicking, sluicing or panning. The fair typist may have been merely careless, or she may have had a private hunch; but if the gold was indeed "placed" on the claims by the claimant, it certainly was a grievous case of topographical error.

⁂

Teniente Topics is the title of a sprightly magazine now being published by employees of the Braden Copper Co. in Chile. The initial number, dated June, 1915, presents the "Early History of the Braden Copper Co.," by William Braden, and contains besides some interesting descriptions of hunting expeditions and sports participated in by members of the Braden staff. It has a section in Spanish, and in many respects is more interesting than many more pretentious magazines. It is officially published by the Teniente Publishing Co., at Sewell, Rancagua, Chile. J. F. Pearce is president and business manager, L. E. Grant editor and A. T. Ward assistant editor. They are to be congratulated on the successful start they have made. The name of the magazine, *Teniente Topics*, was selected by ballot, and it is interesting to note some of the alternatives that were suggested, such as: El Aguila Americana, La Prensa Braden, Andes World, La Voz de Molino, Capos de Nieve, El Tesoro de Teniente, El Grito del Minero, Khaki-People Dope, Dinamita y Concentrados, Snow Flakes and El Tango. The successful name, *Teniente Topics*, was suggested anonymously by S. S. Sörensen, general manager of the Braden Copper Co.

⁂

The New York *Herald* on July 28 published a frightening article to the effect that the shortage of zinc is a greater menace to the arms output than is the labor fight. The writer qualifies as an expert by offering the following remarks:

> Until last winter Belgium produced two-thirds of the world's supply of zinc spelter, obtaining all the ore therefor from the Hartzig Mountains on the borderland of Germany. With the flooding of the mines, all of which are in the war zone, this source of supply has been cut off, it is said, for at least five years. The entire production of zinc ore thus has been restricted to the ore mines at Joplin, Carthage and Web City, Mo., and the Arkansas field.
>
> The maximum capacity of the zinc smelters in the world for making spelter is 1,100,000 tons a year. The capacity of the eight smelters in this country is 350,000 tons. The amount required to fill contracts American munition makers have taken from abroad is 950,000 tons. It requires 18 months to build a zinc smelter, but not one is being built, for the reason that no spelter to operate it could be obtained.
>
> Here is the statement of the American & British Manufacturing Co.:
>
> "There are two brands of zinc spelter—the Edgar and the Horsehead. The Edgar brand is made by the Edgar Zinc Smelting Co., of St. Louis, Mo., and Cherryvale, Kan., and the Horsehead by the New Jersey Zinc Smelter Co. The Edgar Co.'s productive capacity is 2700 tons a month, or a little more than 30,000 tons a year.
>
> "For 20 years the average price was $41 a ton for zinc concentrated ore, 60% metallic contents, with a recovery charge of $35 a ton. Since it has been selling at $120 a ton, the increment in the valuation of the acreage of the Joplin, Carthage and Web City fields has been more than $6,000,000,000. All the gold mines in the world cannot furnish gold enough to pay for that. And these fields are not owned by one or several corporations, but by thousands of individuals.
>
> "It will take five years to get the water out of the zinc mines in the Hartzig Mountains, so that, even though they may be in Germany's hands, she can reap no immediate advantage from them except negatively. But the zinc problem will hit the munition makers harder and sooner than the 8-hour day question."

This was intended to be a serious discussion of the spelter situation, but in fact it is humorous.

Henry R. Merton & Co., Ltd.

The London *Financial News*, of July 27, 1915, states that Henry R. Merton & Co., Ltd., has a nominal capital of £1,000,000 in 30,000 preferred and 70,000 ordinary shares of £10 each. A total of 25,000 preferred and 70,000 ordinary shares have been issued and are fully paid. The directors are: S. Baer, H. Gardner, O. Langenbach, E. R. Merton, Z. Merton and M. Wilson. Alfred Merton and Richard Merton, both of Frankfort-on-the-Main, were formerly directors, but a revised copy of the register of directors filed on Aug. 15, 1914, stated that these two had vacated their seats, owing to non-attendance, "as on Jan. 1, 1914."

Among the shareholders at Oct. 29, 1914, were:

	Shares

Chino Copper Co.'s Second Quarterly Report, 1915

The Chino Copper Co. reports the following production of copper in concentrates for the second quarter of 1915: April, 5,027,548 lb.; May, 6,442,977 lb.; June, 6,984,977 lb.; total, 18,455,502 lb. This gives an average monthly production of 6,151,834 lb., compared with an average monthly production of 3,910,836 lb. for the first quarter of 1915. The total tonnage of ore treated in the three months was 592,200, an average of 6507 tons per day, but the daily average for June was 7317 tons. The average content of the tonnage treated was 2.38% copper. The average extraction for the second quarter of 1915 was 65.31%, corresponding to a recovery of 31.16 lb. of copper per ton of ore milled. For the first quarter the average extraction was 66.12%.

There were produced 11,735 dry tons of concentrates averaging 22.11% copper, as against 21,401 tons of concentrates averaging 27.41% copper for the previous quarter. The ratio of concentration for the second quarter was therefore 14.19:1 as against 18.97:1 for the first quarter of 1915.

The cost per pound of copper produced for the quarter, after allowing for smeltery deductions and crediting all miscellaneous income, was 6.10c., as compared with 6.38c. for the first quarter of 1915. These costs include as usual all operating, administration and general charges and the regular charge of 30c. per ton of ore treated for the extinguishment of mine development and stripping expense.

The financial results of the company's operations for the second quarter were therefore as follows: Net profit from milling operations, $1,937,951; miscellaneous income, rent, etc., $68,597; total, $2,006,548. Dividends paid amounted to $652,455, leaving a net surplus over dividend requirements of $1,354,093. During the quarter there was moved a total of 1,208,360 cu.yd. of material in place. Of this amount there was 871,615 cu.yd. of stripping, while the remainder was equivalent to 643,088 tons of ore. The per-pound costs for this quarter are the lowest that have been made since the property began full operation.

Chronology of Mining for July, 1915

July 1. New wage scale agreed on by miners and mine operators of Joplin.—New workmen's compensation law of Montana went into effect.

July 3. Judge Bourquin in United States Court, Helena, Mont., signed decree ordering sale of Alice Gold & Silver Mining Co.

July 5. New 15-stamp mill of Plumbago Mine, Croesus Mining Co., Alleghany, Calif., went into commission.

July 7. New Jersey Zinc Co. increased its capital stock to $35,000,000.

July 12. Striking miners at Joplin, Mo., returned to work.—Dr. Joseph A. Holmes, Director of the United States Bureau of Mines, died.

July 15. Business section of Valdez, Alaska, destroyed by fire; loss, $500,000.—Coniagas Mine, Cobalt, Ont., celebrated the completion of a decade of mining.

July 17. Property of Iron Mountain Mining Co., Montana, purchased by Federal Mining & Smelting Co.

July 20. Ontario Government appointed a commission to inquire into the feasibility of refining nickel ore entirely within the province.—Work commenced on a 1300-ft. tunnel to carry water from Upper Annex Lake to provide extra power for the operation of the Alaska Gastineau mill at Thane, Alaska.

July 21. New Jersey Zinc Co. paid stock dividend of 250%, amounting to $25,000,000.

July 26. Beginning of suit of the North Star Mines Co. vs. Empire Mines & Investment Co.—Theodore B. Comstock, well-known geologist, died.

July 27. Franklin K. Lane, Secretary of the Interior, announced that the production of radium from Colorado carnotite had passed the experimental stage and was on a successful manufacturing basis.

July 30. Receivers appointed for Ohio Copper Co., following suit of Empire Trust Co. as trustee under the mortgage bond.—Mill of Idaho-Continental mine destroyed by fire.

July 31. Books of the Amalgamated Copper Co. closed, thus terminating its official existence.—Strike at Aluminum Co. of America plant, Massena, N. Y.

Molybdenum Mining in the United States

Owing to the great demand for molybdenum which began a little before the European War, there has been an active search for molybdenum minerals, of which only two, molybdenite (the sulphide) and wulfenite (lead

molybdate), have been found in commercially valuable quantity, says the Geological Survey. In the first half of 1915 the Primos Chemical Co. began producing molybdenite concentrates from a mine near Empire, Colo. This is the first American mine to be extensively operated for molybdenite, though there have been many lesser attempts at mining the mineral.

Steel Production in the United States

The total production of steel in the United States for the year 1914 is given by Bulletin No. 4 of the American Iron & Steel Association at 23,513,030 long tons, which is a decrease from 1913 of 7,787,844 tons; from 1912 of 7,738,273 tons; from 1911 of 167,073 tons. The details of the production are shown in the following table in long tons:

	Acid Tons	Acid %	Basic Tons	Basic %	Total Tons
Bessemer (converter)	6,220,846	26 5			6,220,846
Openhearth	903,555	3 8	16,271,129	69 2	17,174,684
Crucible	80,869	0 4			80,869
Electric	24,009	0 1			24,009
Miscellaneous	3,622				3,622
Tot. l.	7,241,901	30 8	16,271,129	69 2	23,513,030
Total, 1913	10,556,248	35 0	20,344,626	65 0	31,300,874

Of the total production given above, 22,819,784 tons were ingots and 693,246 tons direct castings. Included in the basic openhearth production are 835,690 tons of duplex steel, made from metal partly treated in bessemer converters and finally treated in openhearth furnaces.

The quantity of alloy treated steel reported in 1914 was 646,953 tons, 577,107 tons in ingots and 69,846 tons in direct castings. Of this total, 577,462 tons was openhearth steel.

The total production of steel in 1914 exceeded that of pig iron by 180,786 tons; it was practically the same. This indicates a heavy use of scrap in the openhearth furnaces.

Steel production in the United States for 10 years past has been as follows, in long tons:

	Openhearth Tons	Bessemer Tons	Crucible, etc. Tons	Total Tons
1905	8,971,376	10,944,375	111,196	20,023,947
1906	10,980,413	12,275,830	141,893	23,398,136
1907	11,549,736	11,667,549	145,309	23,362,594
1908	7,836,729	6,116,755	69,763	14,023,247
1909	14,493,936	9,330,783	130,302	23,955,021
1910	16,504,509	9,412,772	177,638	26,094,919
1911	15,598,650	7,947,854	129,602	23,676,106
1912	20,780,723	10,327,901	142,679	31,251,303
1913	21,599,931	9,545,706	155,237	31,300,874
1914	17,174,684	6,220,846	117,500	23,513,030

In the 10 years there has been an increase from 14.3 to 73% in the proportion of openhearth steel.

Finished Iron and Steel

The production of finished rolled iron and steel in 1914 is given in long tons in the accompanying table. It was the smallest since 1908, and was exceeded in seven out of the preceding 10 years.

Articles	Iron, Tons	Steel, Tons	Total Tons
Rails		1,945,095	1,945,095
Plates and sheets	56,590	4,662,656	4,719,246
Nail and spike plate	4,725	33,848	38,573
Wire rods	731	2,430,983	2,431,714
Structural shapes	1,981	2,029,143	2,031,124
Merchant bars	563,171	1,960,460	2,523,631
Bars for reinforced-concrete work		288,471	288,471
Skelp, flue, and pipe iron or steel	264,340	1,718,091	1,982,431
Long angle splice bars, tie-plate bars, etc	50,295	372,757	423,052
Hoops		211,028	211,028
Bands and cotton ties	180	345,739	345,919
Rolled sheet piling, not including fabricated		35,314	35,314
Railroad ties		33,249	33,249
All other finished rolled products	223,802	714,116	937,918
Rolled forging blooms, forging billets, etc	500	331,024	331,524
Exports of blooms, billets, sheet bars, etc	1,461	90,446	91,907
Total Gross tons.	1,167,776	17,202,420	18,370,196

In addition to the rolled-steel piling given in the table, 11,183 tons fabricated piling was reported. Of the finished rolled products given 93.6% was of steel and 6.4% of iron.

Miscellaneous

The production in 1914 included 1,939,185,000 lb. of tinplates and 146,195,000 terneplates, a total of 2,085,980,000 lb., which is an increase of 240,850,000 lb. over 1913, and is the largest output ever reported, with one exception, that of the year 1912.

The production of pipe and tubes in 1914 was 1,737,701 tons; 1,525,551 tons being of steel and 212,147 tons of iron. The make of seamless steel tubes was 90,595 tons.

The production of iron and steel forgings in 1914 was 341,121 tons; only 3675 tons of this quantity being of iron, while 337,446 were steel.

The production of cast-iron pipe in 1914 was 1,160,780 long tons, a decrease of 105,465 tons from the preceding year, or 9.09 per cent.

The production of hammered charcoal iron blooms and billets in 1914 was 39,925 tons, of which only 26 tons were sold as billets, the rest being used by the makers.

Pig Iron Made in 1915

A supplementary Bulletin of the Association gives the production of pig iron for the first half of 1915, in comparison with that of 1914. The figures in long tons are as follows:

	1914 First Half, Tons	1914 Second Half, Tons	1915 First Half, Tons
Basic	5,010,647	4,660,040	5,259,614
Bessemer	4,378,098	3,481,029	4,238,587
Foundry	2,454,540	2,078,714	2,207,375
Malleable	383,139	288,632	278,512
Forge	197,483	164,168	138,789
Spiegel and ferro	86,154	99,864	90,310
Miscellaneous	26,033	23,703	20,604
Total	12,536,094	10,796,150	12,233,791

Of the iron made in 1915, a total of 8,578,625 tons, or 70.1% was for the makers' use; 3,655,166 tons, or 29.9% being merchant iron, for sale.

According to fuel used in the first half of 1915, there were 12,061,808 tons made with coke; 42,487 tons with anthracite and 129,496 tons with charcoal. Low-phosphorus iron is included with bessemer in the table.

U. S. Barytes Output in 1914

The production of crude barytes in the United States in 1914 was 51,547 tons, an increase of 6249 tons over 1913. Stocks on hand at the close of 1914 were 7809 tons of crude domestic barytes, as compared with 9181 tons at the close of 1913. Missouri produces about 65% of the total output of the United States.

There has been considerable recent development in the manufacture of barium salts in this country, according to the Geological Survey. At Melrose, Calif., the Barbour Chemical Works is making barium sulphite, hydroxide, nitrate and chloride. A plant has recently been erected at Charleston, W. Va., and expects to begin the manufacture of barium oxide, hydrate, sulphide, nitrate, chloride and dioxide.

Gold Exports from Colombia in 1914 were 460,238 oz. of crude bullion, equal to 247,326 oz. of fine gold, or $5,122,224. These exports probably represent very nearly the production for the year.

PERSONALS

Pope Yeatman has returned to New York from Chile.

Harry J. Wolf, of Denver, is investigating mining property in the Cripple Creek District.

George O. Argall, manager of the Iron-Silver Mining Co., Leadville, has been in Denver on business.

Howard S. Lee, of San Francisco, was in New York, Aug. 8, and expects to remain there a few days.

Robert Flaherty has gone to Hudson Bay to make explorations on behalf of the Mackenzie & Mann interests.

C. B. Lakenan, general manager of the Nevada Consolidated, has been spending about three weeks in New York.

J. A. Durfee has been appointed metallurgist at the South Side works of the Jones & Laughlin Steel Co. in Pittsburgh.

Daniel L. Beck, Colorado School of Mines, '12, assayer for the Tomboy company, Telluride, is spending his vacation in Denver.

J. E. Chilberg is to examine Samuel Silverman's property on the Stikine River, 140 miles from Wrangell, in British Columbia.

Henry P. Lowe, manager of the Cariman Mining Co., Cardinal, Colo., while visiting in Denver was taken ill Aug. 3 and is in St. Luke's Hospital.

Justin S. De Lury, formerly assistant professor of geology in Idaho University, has been appointed lecturer in geology at the University of Manitoba.

T. T. Read, late associate editor of the "Mining & Scientific Press," has resigned and has accepted a position with the Engels Copper Co., at Engels, California.

Allen H. Rogers has returned from a four months' journey the purpose of which was to inspect the Bawdwin mines in Burma. He made the trip around the world.

J. P. Keane, of Sandon, B. C., with associates is operating the Ivanhoe concentrator as a custom plant and is there concentrating lead-zinc ores from Slocan mines.

Bruce Williams, who has been with W. George Waring for the past seven years, is now associated with him in the Waring & Williams Laboratories at Webb City, Missouri.

H. T. Durant, a well-known British mining engineer and a frequent contributor to the "Journal" is now a lieutenant in the 13th Hampshire regiment and expects to go to the front soon.

O. H. Hahn, whose name is well known to American lead smelters, writes us from Germany that he has been suffering from protracted illness, which has prevented him from doing much work.

A. M. Hunt, W. C. Peyton and Donald E. Fogg, the last formerly of the Thiogen company, have formed a firm for the practice of general chemical and metallurgical engineering at 55 Liberty St., New York City.

Guilford D. Scholl, who has been engaged in leaching and electrolytic work for Phelps, Dodge & Co. at Douglas, Ariz., has gone to Boston, having accepted a position with Walter E. Lummus, chemical engineer.

F. W. McNair, president of the Michigan College of Mines, Houghton, Mich., was entertained at a reception and banquet by the local alumni at the University Club, Salt Lake City, Aug. 4. Twenty alumni were present.

Frank H. Probert announces a change of address to Hobart Building, San Francisco, Calif., where he will continue in practice as consulting mining engineer and in the examination and valuation of mines and mineral lands.

E. E. Campbell, consulting engineer Granby Consolidated, has been in Juneau, Alaska, visiting the different properties. He returned to the company's mines at Hadley, Alaska, and Anyox, B. C., after a week's stay in Juneau.

Albert Burch has resigned as consulting engineer to the Goldfield Consolidated Mines Co. and as vice-president and general manager of the Aurora Consolidated Mines Co. He intends to devote more time to general engineering practice.

W. H. Wright, for several years superintendent of the Ashburton Mining Co. at Folsom, Calif., and a dredge operator of wide experience, has recently joined the engineering staff of the Malm-Wolf Co. of Denver. Mr. Wright has gone to Idaho on professional business.

Clifford E. C. Smith, consulting mining engineer, Toronto, Ont., has been elected a member of the Institution of Mining & Metallurgy, London. He was also recently elected a governor of the School of Mining and College of Applied Science, Queen's University at Kingston, Ont.

Captain Hart Martin, of the Coniagas Mine, Cobalt, Ont., was recently presented with a giant leaf of silver, suitably engraved, on the 10th anniversary of the beginning of mining operations at the Coniagas. The presentation was made by Major Leonard, president of the company.

Milo W. Kreeji, formerly metallurgist at the Boston & Montana Reduction Works of the Anaconda Copper Mining Co., has been promoted to the position of assistant superintendent. He is succeeded in his former position by E. S. Bardwell, who has been general foreman of the concentrator.

J. K. Cram, formerly in charge of operations at the Consolidated Mining & Smelting Co.'s Highland mine, near Ainsworth, B. C., is now superintendent at the company's Sullivan group lead mine in East Kootenay, succeeding C. H. McDougall, who has been transferred to Trail, where the company is making important additions to its smelting works.

A. E. Custer, assayer and chemist, has opened an office at 31, Postoffice Place, Salt Lake City. He was formerly chief chemist of the Bingham Consolidated smeltery at Midvale, and was with the United States government assay office in Salt Lake for four years. Mr. Custer obtained the first option on the alunite deposits at Marysvale, Utah, now known as the Custer Group, which the Mineral Products Co. is developing.

G. W. Riggs of the U. S. Bureau of Mines, first-aid department, is giving first aid and rescue demonstrations to miners in several mining towns along the Mother Lode. Teams from Jackson, Angels Camp, Jamestown and others will take part in the field meet at the Exposition in September and Mr. Riggs' visit is in response to requests for additional instruction and coaching. These teams were formed during the recent visit of the rescue car to California mines.

The Minister of Lands, Forests and Mines of Ontario has announced the appointment of the commission to investigate the nickel industry, which was authorized some time ago. The chairman is George T. Holloway, of London, England, a consulting metallurgist who was recommended by the British authorities. The other members are Thomas W. Gibson, deputy minister of mines of Ontario; Dr. Willett G. Miller, provincial geologist; and Dr. McGregor Young, professor of constitutional law in the University of Toronto.

OBITUARY

Robert Parrish died at Covington, Va., July 23. He was prominent in Virginia mining and had been president of the Oriskany Ore & Iron Co. for some time.

A. H. Henrietta died at Knapp's Creek, N. Y., July 30, aged 71 years. He was for many years a prominent oil operator in New York and Pennsylvania.

William Sterling Porter, second vice-president and general manager of the Associated Oil Co. of California, died at San Francisco, Aug. 9. He was 49 years old. Besides his executive position with the Associated Oil Co., he was vice-president of the Amalgamated Oil Co. and was associated in the directorate of several other oil concerns. In April, 1910, in company with George C. Priestley, he organized the Central Fuel Co., a $15,000,000 corporation. This company held options on a large acreage of Oklahoma oil lands, and it was announced would contract to furnish fuel for the Southern Pacific. Through Samuel Untermyer much of the capital for the company was raised in London.

R. M. Wright died at Marigold, Calif., July 22. He was born at Council Grove, Kan., 62 years ago and was buried there. He was a mining man of the old school in Colorado and for 10 years was employed as underground foreman at the Smuggler-Union at Telluride. He was one of the foremost men in the Smuggler-Union defense against the strikes and rioting of the Western Federation of Miners. In the past 10 years he was employed by the same interests as bookkeeper for the Ashburton Gold Dredging Co. at Folsom and the Marysville Gold Dredging Co. at Marigold, Calif. His wife was in Philadelphia at the time of his death and his son, W. H. Wright, mining engineer, of San Francisco, carried the remains back East for burial. Mr. Wright's death was due to asthma, from which he suffered for several years.

George G. McMurtry, of New York, died at Atlantic City, N. J., Aug. 6, aged 78 years. He was for many years well known in the Pittsburgh steel trade, and under his charge as manager the extensive works of the Apollo Steel & Iron Co. at Vandergrift were built. When the company was

absorbed by the American Sheet & Tin Plate Co. he became a director and president of the consolidation, and later chairman of the board. After the change he removed from Pittsburgh to New York. He was interested in other companies and was a director of the American Can Co., a director of the Chicago, Rock Island & Pacific Ry., the Pittsburgh Trust Co., and the Rock Island Trust Co. He was a member of the Metropolitan and Sleepy Hollow Country Clubs and the Automobile Club of America. He is survived by his widow, who was Miss Clara Lothrop, and by three sons. The works at Vandergrift which he built were the first in the Pittsburgh district in which careful provision was made for the safety and comfort of the employees.

Dr. Thomas Bliss Stillman died in Jersey City, N. J., Aug. 10, aged 63 years. He was born at Plainfield, N. J., studied at Rutgers College, at the Fresenius Laboratory at Wiesbaden, Germany, and at Stevens Institute, Hoboken. From 1883 he was instructor in analytical chemistry at Stevens Institute, and later professor. In 1903 he was made professor of engineering chemistry and in 1909 retired from active work as an instructor. For several years he had been at work on a revision of his book on "Engineering Chemistry." Professor Stillman held many important positions in New Jersey. In 1884 he was appointed state inspector of oils, in 1911 he was appointed city chemist of Jersey City and Bayonne, and held those offices until his death. Professor Stillman was also appointed an examiner in chemistry for the Municipal Civil Service in 1911, and was later appointed chemist to the Medical Milk Commission of Newark, N. J. He was a member of the American Chemical Society, the Society of Chemical Industry of London, the American Institute of Mining Engineers, the International Association for Testing Materials, the American Electro-Chemical Society, the Société Chimique de Paris and the fraternity of Phi Beta Kappa. Professor Stillman was also a corresponding member of the Edinburgh Society of Arts and Sciences and the Deutsche Chemische Gesellschaft. He leaves a wife, two sons and a daughter.

Alexander Milne, who died Aug. 1 at his residence, White Plains, N. Y., aged 82 years, was senior member of the firm of A. Milne & Co., New York, Boston and Chicago, steel and iron merchants. Mr. Milne was born in Montrose, Scotland, but went to Sheffield, England, when about 19 years of age and entered the employ of Henry Roessel & Co., steel manufacturers and merchants, and later with the well-known firm of Vickers Sons & Co., Ltd., who in 1869 sent him to this country to promote the sale of its steel in America. Two years later he was associated with the firm of Naylor & Co., and became a member of the firm in 1883; while associated with them he took an active part in the management of the Norway Steel & Iron Company, Boston, Mass., where his practical knowledge of the manufacture of steel acquired in Sheffield proved of great value in the development of the business of that company. He withdrew from the firm of Naylor & Co. in 1887 and established the firm of A. Milne & Co., iron and steel merchants and representing Alrutz & Co. and their successors, C. & J. Svedberg, of London and Stockholm. He was well and favorably known among the iron and steel manufacturers of this country, remaining in active business up to the time of his death. Mr. Milne was interested in religious and charitable matters and was the first president of the Y. M. C. A., of White Plains. He is survived by his wife, a son, Alexander Milne, Jr., and a daughter, the wife of W. Russell Silvers, of Cranberry, New Jersey.

INDUSTRIAL NEWS

Gullén & Dole, Sucesories de José Juliá, Trujillo, Honduras, would be interested in receiving catalogs concerning mining equipment and stamp-mill machinery.

E. M. Sargent, of Balfate, Honduras, via New Orleans and Trujillo, is interested in the installation of a cyanide plant, and would like to receive catalogs of cyaniding machinery and equipment.

The Calumet & Hecla Mining Co. has installed 23 more large Hardinge mills, 16 of these for their new regrinding plant, six for the Ahmeek Mining Co., and one for the Lake Mining, Smelting & Refining Co.

The Morse Bros. Machinery & Supply Co. of Denver recently shipped seven carloads of machine tools to various manufacturers in the East engaged in war contracts. Most of the equipment was turret and engine lathes.

A new method of recording the cost of various conveyor belts in operation has been worked out by the B. F. Goodrich Co., of Akron, Ohio, in the interest of belt users, which will send on request a card giving the details of the system.

The Mesta Machine Co. is distributing a blue-print giving the solution in graphic form of various gear and pulley problems. That is, in gearing, if the horsepower transmitted is given, with the revolutions per minute and pitch speed, the pitch diameter and pitch load may be determined.

The Morse Bros. Machinery & Supply Co. of Denver have recently installed a complete flotation testing plant in its Denver storeroom, the use of the plant being offered free to those wishing to make their own tests and experiments along this line. Competent assistance is also given to those desiring it, and free preliminary tests will be made on any ores or tailings sent them. Quite a number of the recent flotation installations in Colorado have had their inception at their plant.

The Spray Manufacturing Co., which was recently incorporated to construct spray cooling systems, gas scrubbers, odor and fume condensers, etc., will carry on general engineering work involved in the use of spray systems, and owing to the broadening of the scope of its work, has changed its name to the American Spray Co. The personnel of the company remains unchanged, with A. G. Eneas president and chief engineer. Offices remain at 201 Devonshire St., Boston.

Edward M. Hager, whose election as president of the Hager Portland Cement Co. has been announced, was graduated from the Massachusetts Institute of Technology in 1893. In 1899 he was appointed manager of the cement department of the Illinois Steel Co. The manufacture and sale of universal portland cement was carried on by the Illinois Steel Co. until 1906 when the Universal Portland Cement Co. was formed with Mr. Hager as its president. Mr. Hager resigned the presidency of the Universal Portland Cement Co. in February of this year to form a new company for the purpose of acquiring a chain of Portland cement plants extending aeross the country.

TRADE CATALOGS

Carbo Steel Post Co., Chicago, Ill. Catalog. Steel Poles. 20 pp., Illus., 9¼x4 inches.

Blackmer Rotary Pump Co., Petoskey, Mich. Catalog. Rotary Pumps. 32 illus., pp., 6x9 inches.

The Gardner Governor Co., Quincy, Ill. Circular A-C 13. Air Lift Pumping System. 16 pp. illus., 6x9 inches.

Kerr Turbine Co., Wellsville, N. Y. Bulletin No. 54. Economy Turbo-Generators. 32 pp., illus., 6x9 inches.

De Laval Steam Turbine Co., Trenton, N. J. Catalog F. Centrifugal Blowers and Compressors. 64 pp., illus., 6x9 inches.

R. D. Nuttall Co., Pittsburgh, Penn. Catalog No. 12. Mine and industrial gears, pinions, trolleys. 62 pp., Illus., 7x9 inches.

Bethlehem Foundry & Machine Co., S. Bethlehem, Penn. Pamphlet. Tantiron. Chemical Resistant Metal. 8 pp., 6x9 inches.

The Du Pont Nitrate Co., of Wilmington, Delaware, is installing a 24-in. and 48-in. Symons disk crusher in the nitrate fields of Chile.

Chicago Pneumatic Tool Co., 1010 Fisher Building, Chicago, Ill. Bulletin E-36. Duntley Electric Grinders. 8 pp., illus., 6x9 inches.

Allis-Chalmers Mfg. Co., Milwaukee, Wis. Bulletin No. 1632. Centrifugal Pumps and Centrifugal Pumping Units. 44 pp., illus., 7½x10½ inches.

Hardinge Conical Mill Co., 50 Church St., New York. Pamphlet. Reprints of Articles from Technical Papers on Hardinge Mill. Illus., 6x9 inches.

Stephens-Adamson Mfg. Co., Aurora, Ill. Section 5, General Catalog No. 19. Sand and Gravel Washing Plants, Screens, Cars, Hoists, Etc. 622 pp., illus., 6x9 inches.

Chalmers & Williams, Inc., Chicago Heights, Ill. Bulletin. Section U, Fourth Edition. Symons Disk Crusher. Spanish translation of Bulletin, Section R. 24 pp., illus., 7x9 inches.

National Tube Co., Frick Building, Pittsburgh, Penn. Catalog J. "National" pipe for steam, air, gas, water, "Kewanee" unions and specialties, iron and brass fittings, valves, etc. 394 pp., Illus., 5x7½ inches.

Brown Hoisting Machinery Co., Cleveland, Ohio. Catalog U. Brownhoist Transfer Cars and Larries. 32 pp. illus. 9x6 in. Illustrations and brief descriptions of some of the important transfer cars built by this company for important metallurgical plants.

Editorial Correspondence

SAN FRANCISCO—Aug. 4

A Receiver for the Presidio Mining Co. has been asked in the U. S. District Court by minority stockholders. The plaintiffs are Captains W. S. Overton and Carl A. Martin, of the U. S. Army, who appear also for other stockholders residing in the East. These include also Gen. Anson Mills, U. S. A., retired, of Washington. The plaintiffs represent 22,753 shares of the total issue of 150,000 shares. The complaint alleges that William S. Noyes owns or controlls 97,933½ shares and that he has so manipulated the finances as to obtain title personally to mining property in Texas which should belong to the corporation. The suit demands an accounting. Judge W. H. Sawtelle sitting at San Francisco issued a temporary restraining order and an order to show cause why a receiver should not be appointed.

Chrome Deposits in California are attracting attention of investors. Clarence M. Oddie and associates, of San Francisco have recently purchased claims near Dunsmuir and near Willows. It is reported that French investors are associated with Mr. Oddie in these purchases. Chromite occurs in 15 counties in California, and nearly all of the recorded claims have produced some ore. The industry has been largely retarded by lack of transportation facilities, the mines or deposits generally being situated at such distance from railroads as to make freight transportation expensive. The industry has produced about 31,000 tons of ore of a total value of approximately $400,000 since 1887. The production in 1913 amounting to 1180 tons came from Calaveras and Shasta Counties. The 1912 production of 1270 tons came from Fresno, Shasta and Siskiyou Counties. San Luis Obispo County was at one time a large producer and up to 1890 had produced 11,000 tons which was shipped to Baltimore and Philadelphia.

The First Team to Win, as a prize, the privilege of representing its state and section in the Third Annual Joint Field Meet and Demonstration of the United States Bureau of Mines and the American Mine Safety Association, to be held in San Francisco, Calif., Sept. 23-24, is the Lehigh, Oklahoma, team. This team won the interstate championship of the Southwest in the contest held recently at Kansas City between teams representing six Southwestern states, these teams having been selected as a result of state-wide meets previously held in the various states. At the Kansas City meet, which was held in Convention Hall, the following scores were made, out of a possible 900:

Lehigh, Oklahoma, team	888
Frontenac, Kansas, team	883
Hocking, Iowa, team	843
Texas team*	824
Bevier, Mo., team	823
Calhoun, Okla., team (representing Arkansas)	812

*The regular Texas team did not appear at the contest, the team listed being a scrub team picked from the audience in order to make the six teams. This team did not compete for the grand prize.

Apex Litigation has been started by the North Star Mines Co. of New Jersey against the Empire Mine & Investment Co. of San Francisco. Both companies operate at Grass Valley, Nevada County. It was believed for a time that the controversy might be settled out of court, or before getting into court. Engineers were employed by both sides but it appears that no satisfactory settlement could be reached without a law suit. The complaint filed in the U. S. District Court alleges that the Empire has invaded the North Star by two shafts known as the Empire and the Pennsylvania which are situated east of the North Star property. It is claimed that $10,000 worth of gold-bearing ore has been taken out through the Empire shaft and $5000 worth by drifts from the Pennsylvania shaft. The lowest level of the North Star at 4600 ft., incline, disclosed a vein of good ore. The Empire claims apex rights to a part of this vein. This claim is based mainly on the results of the suit of the Pennsylvania against the W. Y. O. D. in which the plaintiff obtained a verdict and absorbed the defendant company. Both these companies were later absorbed by the Empire. That litigation was costly and showed a complex vein structure, which may or may not aid in the settlement of the present suit.

Mount Lassen Mud promises to make some amends to the farmers for the devastation of crops and tillable ground. The mudflow from the big eruption on May 21, covered large areas in Hat Creek valley, filled up the stream causing overflow to alfalfa fields. Many of these fields have produced extraordinary crops of alfalfa which has come up through the mud. In some places the alfalfa is a foot and a half high and will make a ton and a half to the acre. In some cases the alfalfa was too young to push through the mud, but the soil has not been killed. Another advantage resulting from the filling up of Hat Creek is that a crooked stream has been made straight by digging a canal and changing the meandering course of the creek. In the lower part of the valley out of the range of the mudflow the crops have never been better. And this in spite of the fact that the sulphur fumes extended far beyond the flow of the mud. Mount Lassen is now a good mountain. At any rate Mr. Diller of the U. S. Geological Survey says that the eruption late in July may be counted as the last of any importance. The fact is that none of these eruptions have been important from a geological viewpoint. It has been somewhat interesting to travelers, many of whom have preserved bottles of fine crushed stone or dust which the self-styled guides have called ashes. Since there has been no fire there have been no ashes. It is pleasing to reflect that after all the farmers will benefit from Mt. Lassen's behavior.

The Apex Controversy between the Kennedy Extension Mining Co. and the Argonaut Mining Co. in Amador County may be finally settled by the purchase of the Muldoon mine by the Argonaut. The claim of the Kennedy Extension that the apex of the Argonaut ledge was in Muldoon ground was denied by Judge Wood in the Superior Court after a long and expensive trial. Subsequently the plaintiff endeavored to reopen the case and this was also denied. A notice of appeal to the Supreme Court was filed but the appeal has not been taken and it is now intimated that the ground owned by the Kennedy Extension will be purchased by the Argonaut, not so much for its value as for ridding the Argonaut of further annoyance of lawsuits. The question of apex was stirred up a good many years ago by Mr. Muldoon the owner of the Muldoon mine and the Argonaut could have purchased the entire property at that time for a sum not exceeding $50,000. The manager of the Argonaut at that time did not consider the Muldoon of sufficient importance either as a mine or a neighbor to buy it at any price. The subsequent law suit has cost the Argonaut a large amount of money and has retarded development and operation to an extent that would have been very disastrous to any other than a large producer. While it is not believed, by persons acquainted with the legal status and the geological conditions, that the Kennedy Extension will ever carry the case to the Supreme Court, it may be the part of wisdom to get rid of such a possibility by purchasing the Muldoon property outright.

DENVER—Aug. 5

Production Cripple Creek District for June, according to reports from plants treating its ores, was $1,127,685 in gold, from a gross tonnage of 82,050. Of this tonnage, about 62½% was of high-grade ores shipped to outside plants for smelting and cyanidation.

Colorado Fuel & Iron Co.'s steel works at Pueblo are doing record business, working to capacity with 3190 men on the payroll. Large orders for 90-lb. rails are being filled for the El Paso & Southwestern, Salt Lake & San Pedro and the Denver & Rio Grande railroad systems. The merchant mill department is busy with important shipments to the Chinese government.

Deposits of Gold at the United States Mint, Denver, during the fiscal year ending June 30, 1915, amounted to $430,000,000 (in round numbers), an increase of about 15% over the preceding year. This gold was received from a greater number of mining camps than ever before.

Roosevelt Tunnel Will Be Pushed 8500 ft. from its present breast at the western margin of the Cripple Creek basin near the Elkton mine. Work will be done on company account instead of, as contemplated, under contract and will be superintended by C. H. Fuller who was superintendent of the project during the original contract held by A. E. Carlton. It is estimated that the advance will cost $20 per foot. Contemplated terminal will be in Golden Cycle territory where it appears certain that drainage will have been established for the whole district. The directors of the drainage enterprise

are A. E. Carlton, William Lennox, Irving Howbert, John T. Milliken, James F. Burns, Irving T. Snyder, A. J. Zang and Richard Roelofs. Last two members have just been appointed to fill vacancies caused by resignation of A. L. Burris and the death of Frank F. Castello.

Mine Operators Are Preparing for the new workmen's compensation law. Any employer may elect not to carry indemnity insurance for his employees, but he must public announce this decision and must be prepared to protect himself in suits brought against him for injuries sustained by employees and he will have practically no defense left him under the law. There are four ways in which he can comply with the insurance features of the new law, viz., by establishing his responsibility and satisfying the commission that he is able to carry all such risks; by purchasing policies for his employees from companies writing liability insurance; by purchasing such insurance protection from the state's compensation insurance fund; or by cooperating with other employers in forming a mutual insurance company to be approved by the insurance commissioner. Regular insurance companies have been so eager in soliciting patronage that the state's commission found it necessary to announce a resolution forbidding all insurance concerns from offering or giving any rebates, refunds or profit-sharing endorsements. This means that numerous contracts already entered into must undergo revision and that the flat rates as published must be rigidly adhered to. W. W. Greene, manager of the state's insurance fund, says that he has already arranged for indemnity insurance on $5,000,000 of payroll to metalliferous miners and expects to receive applications for insurance on approximately $2,000,000 more payroll.

Empire Zinc Co. has purchased the holdings of the Eagle Mining & Milling Co. near Belden, Eagle County, Colo. The property comprises two mines, aërial tramways, water rights, hydro-power line and fine mill on the main line of the Denver & Rio Grande R.R. in the cañon of Eagle River. W. H. Paul, manager of the Empire company, will have control of future operations with Mr. Boyd as superintendent, and plans are made for doubling the output. The properties comprising the mining group were formerly owned by two distinct companies that worked their respective groups for gold-silver orebodies, which occur as irregular masses in pitching sedimentaries. During early operations, the ores were thoroughly oxidized and yielded well in the native metals. As depth was gained sulphides became abundant and sphalerite proved so predominant that it precluded profitable mining under the then prevailing penalties exacted by smelters. This handicap was but half the trouble that closed down the Iron Mask and the Rocky Point mines. The workings of the former mine were within a geological series underlying that containing the Iron Mask orebodies. Following their oreshoots into the mountain, owners of the Rocky Point mine delved within the boundary planes of the other company's holdings. Litigation ensued and both mines remained idle for many years. Meanwhile, efficient methods for concentrating zinc ore having been invented and the market for such material having been created, these properties were brought to the attention of S. N. Hicks of Denver, who purchased them outright and, with the coöperation of Charles H. Hanington, reopened the mines and added the equipment that has been treating an increasing tonnage for several years past. The run-of-mine averages about 17% zinc and 1.5% lead. Milling includes pulverizing, roasting in two six-hearth Dewey units, cooling,, magnetic separation, regrinding, sizing and table concentration. One ton of galena concentrate is produced with each 10 tons of sphalerite concentrate. The former will average 75% lead, the latter about 48% zinc. Average daily tonnage of ore treated during last year was about 120 tons and earnings were more than $250,000. The plant includes a 120-hp. Pelton wheel.

SALT LAKE CITY—Aug. 5

The Salt Lake Stock & Mining Exchange is showing considerable activity, with inquiry and trading in local stocks from outside points. During July there were traded in 1,973,319 shares, with a valuation of $279,969, the sales for the last week being valued at $82,860. The heaviest months trading recently was in June, when the transactions were valued at $380,964.

Tenth Biennial Report of State Coal Mine Inspector, J. E. Pettit, for the years 1913 and 1914, shows that coal produced during the latter year amounted to 3,149,491 short tons, coke to 348,806 tons, an increase of 10% over 1913, the hydrocarbon production to 17,480 tons. There were employed 4068 coal miners, who worked an average of 196 days during the year. For each accident that occurred 20,720 tons of coal was mined, and one life was lost for every 165,236 tons mined. Carbon County had the largest output and Emery County next.

The Utah Power & Light Co., which serves a large part of Utah, Idaho, and Colorado, has completed plans for extending its electric power and light service into Emery and Carbon counties in eastern Utah. The company's transmission lines will be extended from the present system; and power will also be developed from hydro-electric plants. It is proposed to erect a steam-turbine generating station in the center of the district, pending the completion of the water-power plants. The Scofield electric-light plant and a power site on the Price River near Helper have been purchased.

A New Mill at Park City is to be constructed by C. C. Broadwater of the Merrill Metallurgical Co. and San Francisco interests to treat tailings on the Grasselli Chemical Co's property, recently secured under bond and lease. Plans are being drawn by Kirk & Leavall of this city; and it is understood that the mill will be similar to that of the Big Four Exploration Co. just completed to treat tailings at Atkinson. Work will be started shortly on the millsite northwest of the tailings. A part of the machinery in the 125-ton mill now on the property will be used. Beside straight concentration, flotation equipment will be installed. The dumps are estimated to contain 300,000 to 400,000 tons of tailings carrying zinc and lead-silver.

Suit against the Ohio Copper Mining Co., Clark Grove, Edward McCormick, and Charles T. Clark as trustees in bankruptcy for the Ohio Copper Mining Co., the Bingham Central Ry. Co., and the Utah Power & Light Co., was filed in the district court July 16, by the Empire Trust Co., as trustee, to foreclose a mortgage given to secure $2,000,000 worth of bonds. It is stated that $1,242,000 of the outstanding bonds are entitled to benefit under the mortgage, and that the remainder have been retired, or are held by the trustees in bankruptcy for the Ohio Copper Mining Co. and not entitled to benefit. The court is asked to appoint a receiver to handle the property, to order a foreclosure, and to quiet title to the property as against the various properties claiming interest in it. The bonds were issued by the Ohio Copper Co., and were secured by mortgage on the company's Bingham properties. The company went into the hands of receivers September, 1914, and was later turned over to a board of trustees in New York, who leased the property to A. Frank and associates, now operating it.

SEATTLE—Aug. 2

A Ledge Carrying Free Gold has been found in the Tolovana district and has been traced for nearly three miles along the left limit of Livengood Creek, where gold was first discovered in the camp. The ledge is 12 ft. wide and promises to develop into a big proposition.

Striking Miners in Fairbanks have concluded that $4 for eight-hours' work is better than idleness and have gone back to work. The strike which was a matter of a week, for a time assumed serious proportions and threatened to curtail the output of the camp which is generally expected to be larger this year than last. The operators issued an ultimatum that they would pay only $4 for eight-hours' work and no more and would close down the placer camp for the entire season if necessary. Every claim that was in operation before the strike is now working again to capacity; many of the operators having put on extra crews to make up for the lost time, so that no effect is likely to be shown in production of the camp.

Fifty Dredges in Operation on the Seward Peninsula is the prediction of several of the placer operators in the Nome district who state that there is no question of the future of the dredging industry in that section. Last year 42 dredges operated successfully on the peninsular and this year two more are to be installed and by the end of the year it is expected that 50 will have been constructed. The newest enterprise to arrange for the installation of a dredge on the peninsula is that of A. J. Jarmouth and associates of New York. They will install a 5-cu.ft. bucket Bucyrus gold dredge on Cripple Creek 12 miles from Nome. The machinery is to be shipped north this fall so that the dredge can be put up next spring where they have secured several miles of good placer ground which will be worked systematically.

More Mining Work Is Going on Around Valdez this summer than at any time in the last 10 years. Mines in the interior are also being opened and developed. The Rutherford-Ramsay property near the Valdez Glacier is working 20 men, while at the Granite a crew of 70 men is employed, operating the two big mills and blocking out ore for future crushing. The Tenas Pontius property near the Columbia Glacier is working a crew of men and several bricks valued at $11,000 were recently brought to Valdez from the claims. The Granby copper mines in Solomon basin are being developed and the big equipment on the claims placed in shape for handling the ore that will be taken out this fall. The Ellamar copper mine is working more men than at any time in the history of the mine and many new properties are being investigated.

SEWARD, ALASKA—July 28

Moose Pass, a district but forty-five miles north of Seward, has been the cause of considerable excitement lately because of the arrival of a couple of well-known prospectors bringing some exceptionally rich specimens of gold-bearing quartz. Various small ledges carrying sufficient free gold to be visible to the naked eye have been known to exist in this section, certain prospectors having made high wages by crushing the quartz in a hand mortar and separating the gold by panning. Early in July J. B. Slater, operating a small arrastre, took out $150 in a week's time. The samples of the new strike now on exhibition are far richer than those hitherto reported, the quartz being studded with lumps of gold as large as duck shot. Like most of the ledges thus far discovered in the district, the one just located is rather narrow, its maximum width not being over 14 in. The discoverers have exposed the vein for about 60 ft. and estimate that for this distance, the ore will average at least $1000 to the ton. Some of the crushed quartz has yielded $3 to the pan and it is asserted that a man can easily mortar an ounce of gold per day out of the solid rock.

KELLOGG, IDA.—Aug. 2

Stock Sales by the 20 Brokers who are members of the Spokane stock exchange aggregated not less than $1,500,000 in July, and it is believed this record will be eclipsed in August. From the best information obtainable the number of transfers during the month was greater than for any previous month in the history of the organization, but the value is less, as the principal trading has been in the low- and medium-priced issues, while in former periods of mining activity, particularly during the "boom" of 1906, the high-priced securities were the leaders.

A Bureau of Mines Coöperative Experimental Laboratory to investigate the proper treatment of the zinc-lead ores of the Coeur d'Alenes will be established in Idaho. D. A. Lyon, metallurgical expert of the Bureau, who, with F. G. Cottrell, visited the district last week, is credited with the announcement of intention, providing the State University succeeds in getting the right man for head of the mining department. An effort will also be made to develop a method of producing metallic lead and zinc from their ores without smelting, in line with the experimental work now being done at the Bunker Hill & Sullivan. Doctor Lyon stated that some of the mines in the West were saving only 50% of the metals in their ores and that the Bureau of Mines hoped to develop special processes of treatment by which the extraction could be raised to 80%. He also stated that it was planned to establish experimental laboratories in the Coeur d'Alenes even if none should be placed at Moscow.

HOUGHTON—Aug. 10

As An Example of Prosperity in the copper country, recently two of the men on a railway payroll were down for checks of $110 each for two weeks work. Business houses report a large number of Calumet contract miners' checks running in the vicinity of $100 for the half-month pay day.

The Production of Copper from Various Lake Superior Mines for the month of July, based upon rock tonnages, estimating return in stamp mill and refinery are: Calumet & Hecla, 8,050,000 lb.; Quincy, 2,000,000, Copper Range Consolidated, 5,400,000; Winona, 200,000; White Pine, 450,000; Houghton Copper, 70,000; Tamarack, 450,000; Osceola Consolidated, 1,900,000; Ahmeek, 2,300,000; Wolverine, 700,000; Mohawk, 1,300,000; Franklin, 270,000; Centennial, 280,000; Allouez, 850,000; Mass Consolidated, 500,000; Superior, 360,000; Hancock, 175,000; La Salle, 125,000; Victoria, 260,000.

A Record Production of 27,000,000 lb. of copper was made in the Lake Superior district in July and 28,000,000 lb. seems assured for August. While it is stated on the best authority possible that the bulk of the copper produced here is sold up to September and in some cases to October, the fact remains that the metal is beginning to accumulate at some of the docks, particularly the Dollar Bay dock of the Calumet & Hecla subsidiaries and at the Copper Range dock. The amounts are not disconcerting as yet and a few vessels could clean them up, but, after the rush of a few months ago when every scrap of copper was cleaned out in a hurry, these dockage evidences occasion some talk locally among copper-share owners.

ISHPEMING, MICH.—Aug. 8

The Pittsburgh & Lake Angeline Iron Co., which has operated the Lake Angeline mine at Ishpeming since 1864, and which owns considerable land in Northern Michigan, will offer all of its holdings in the state for sale at public auction on Sept. 15, 1915. All of the property of the company, real, personal and mixed will be sold. This will mark the end of one of the famous Michigan iron companies, as the Lake Angeline mine has long been a producer of high-grade bessemer iron ores, and is now about played out. For the past year the company has been operating the mine with a small force and getting out the little ore that remained. The Mitchell mine, at the Winthrop, also belongs to the company and will be sold. It is believed that the property of the Pittsburg & Lake Angeline Iron Co. will be bid in by the Jones & Laughlin Ore Co., which owns a part of the Lake Angeline stock. The two companies have been working together and have been under practically the same management for years. The Lake Angeline mine has produced 9,003,000 tons of iron ore. The profits have been well up into the millions, as the ores were the richest mined in the Lake Superior district and always commanded a premium in the market. Some mining men believe that there is a possibility of finding more ore in the east end of the mine and it would not be surprising if the Jones & Laughlin company should start exploring there if they come into possession of the company's holdings.

DULUTH—Aug. 7

Iron Ore Shipments from Duluth-Superior harbor to Aug. 1 were 2,126,807 tons ahead of same period in 1914. Figures are as follows:

Dock	1915	1914
D. M. & N.	6,710,660	2,949,285
Iron Range	3,993,704	2,898,771
Gt. Northern	2,686,778	5,423,034
Soo	388,052	272,005
N. P.	25,344	43,636
	13,714,538	11,587,731

Figures for the month of July are:

	July, 1915	July, 1914
D. M. & N.	2,414,849	1,169,410
Iron Range	1,413,456	1,162,315
Gt. Northern	1,150,310	1,806,273
Soo	143,344	175,153
N. P.	19,784	6,807
	5,143,743	4,319,958

JOPLIN—July 31

Joplin Mines Cannot Be Unionized. The outstanding event in this district last month was the total collapse of the miners' strike following a strenuous campaign to unionize the mines. About the middle of June some labor agitators from the Southeastern Missouri lead fields came to this district and with the assistance of a few local malcontents began organizing locals of the American Metal Miners Union. On June 28 they began visiting the more important mines throughout the district and ordered the miners to cease work after presenting an arbitrary wage scale which the operators almost without exception refused. At the end of the week approximately 4000 were out, many of whom joined the new union. Mine owners made no attempt to operate and in a number of instances voluntarily shut down. In a few days the fact began to dawn on our local miners that they had been bluffed into quitting good jobs at the highest wages they had ever received, by a lot of outsiders who had neither interest or residence in this district. Merchants throughout the district immediately notified the miners that they would not extend credit to men who had quit work. The first Saturday found both empty pockets and empty larders in many miners' homes. Before the end of the second week miners began holding meetings in the various camps of the district, from which the strike leaders were barred, with the result that operators were petitioned to reopen the mines at the wage scale in force when the strike started, and hundreds of miners who had been coerced into joining the union tore up their cards. On July 12 operations were resumed all over the district, and the strike leaders took their departure. This district cannot be successfully unionized, for the reason that a majority of working miners are always carrying an interest in some prospect and as soon as these prospects develop into mines the miners leave their jobs and go to work in their own diggings, thus becoming employers of labor instead of employees, under which conditions they have no use for the union.

TORONTO—Aug. 7

The Recent High Prices for Zinc has turned attention to the ore deposits of this metal in Ontario. A mining engineer representing certain Toronto interests passed through Fort William en route to Rossport, a village in this district located on the north shore of Lake Superior, to inspect the abandoned Zenith zinc mines, 12 miles from that town. If his report on the property should be favorable it is the intention of the syndicate to reopen the mine and to operate it as long as the present remunerative prices obtain. Although there are several well-known deposits of zinc in the Province, past low prices have not encouraged mining operations. Government reports show that since 1910 no zinc has been mined in the Province

The Mining News

ALASKA

GRANITE GOLD (Port Wells)—Lower adit finished and raise to mine workings started.

KOOTZAHOO INLET (Juneau)—J. C. Hyde, C. J. Gundlach, John Sandman, and Peter Carlson are sinking shaft on 4-ft. dipping vein of coal (grade between lignite and semi-bituminous) at Kootzahoo Inlet. Expect to diamond drill property later.

ALASKA CONSOLIDATED (Juneau)—H. K. Welch has been examining Harrington claims, adjacent to Alaska Gastineau and Alaska Gold Belt properties, and has also been examining Auk Bay properties. Mr. Welch expects to return to New York in near future to report on his work to directors of company.

ALASKA INDUSTRIAL (Sulzer)—Ex-governor Sulzer of New York has been in consultation with General Manager Charles A. Sulzer regarding plans for extension of Sulzer mine. Plans are to drive lower adit tunnel to avoid hoisting ore. Sulzer mine has been continuous producer for 14 years, with exception of few months just after start of European War.

ALASKA GOLD (Juneau)—Annex Creek power-project tunnel to tap upper lake started July 23. Tunnel will have circular section 8 ft. in diameter. Distance to drive, 1200 ft. before raising to lake bed. Water will be conducted from mouth of tunnel through pipe to power house on beach about a mile and a quarter from tunnel. H. L. Wollenburg, chief engineer, John Wilcox, superintendent, and Byron Olson in complete charge of tunnel.

ARIZONA

Cochise County

CALUMET & ARIZONA (Douglas)—Smeltery with two blast furnaces, three reverberatories and twelve roasters made output of about 7,250,000 lb. of copper in June, establishing new high record.

Gila County

INSPIRATION (Miami)—Is now treating 2500 tons of ore daily and next month expects to reach 7000 tons daily. Reported saving 27 to 28 lb. of copper per ton compared with 25 lb. estimated.

Greenlee County

ARIZONA COPPER (Morenci)—Is installing Callow system, after having investigated other methods of flotation.

Pima County

CLEOPATRA and HALL (Jerome)—These properties, have been under option to United Verde Copper Co. It is said that formal transfer has been made. Said to involve approximately $1,000,000.

NEW CORNELIA (Ajo)—Announcement from C. & A. offices that Jas. H. Maxey, of Yuma, has been awarded contract to build 44 miles of Tucson, Cornelia & Gila Bend railroad from mine to S. P. main line at Gila Bend. Contractor was lowest of 11 bidders.

IMPERIAL (Ray)—American Smelting & Refining Co. is reported to hove ordered examination of this mine in Ray district with view of purchasing. Imperial was recently purchased by Lee Goldschmidt, of Tucson at sheriff's sale. The property has record of producing more than one million dollars worth of ore. The ground to be thoroughly explored by churn drills in order to determine extent of copper deposit.

Pinal County

KELVIN-SULTANA (Kelvin)—Company is shipping three cars of concentrates a month to Hayden. Leasers recently shipped car of carbonate ores. South crosscut on 500 level has been advanced 195 ft.

CALIFORNIA

Eldorado County

LATROBE, a mining town and railroad station in the southwestern part of the county, was almost entirely destroyed by fire recently. It has been an important shipping point for mines in the Nashville and Plymouth districts. The fact that the citizens declined outside assistance is evidence that the town will be rebuilt and resume its place as an important point on Southern Pacific R.R.

FROG POND (Garden Valley)—Installation of 10-stamp mill being arranged for. Underground work at present consists of sinking and crosscutting. Headframe and hoist have been installed. About 200 tons of ore on dump is reported to assay $10 to $15 a ton. F. C. Levitt is superintendent.

UNION AND WARD (Placerville)—These gravel mines, recently bonded to J. Willmans, will be reopened and will be operated by drifting methods. Both properties are equipped with mills.

Inyo County

TUNGSTEN DEPOSITS west of Bishop secured by lease and purchase option by John MacIver are being prospected. Ore will be handled by jigging.

Kern County

WERINGER (Woody)—Reported that A. P. Peake of Butte, Mont., has purchased an interest in this copper mine and that equipment necessary for development to 500-ft. point, consisting of hoist and compressor plant, will be installed immediately.

San Bernardino County

ATOLIA (Atolia)—Installation of new mill for treatment of accumulated tailings is in progress, which will double tungsten production of these mines. Mill will be electrically driven and camp electrically lighted. Twenty-five tent-houses are being built for company employees. Leasers on company ground report excellent results. There is an air of progress at Atolia which is situated about five miles from Randsburg.

SALISBURY (Zabriskie)—Eleven 6-ton autotrucks manufactured at Salt Lake have been contracted for, to be used in hauling ore from this lead-carbonate mine. Seven of the trucks have already arrived at Zabriskie which is on Tonopah & Tidewater R.R. Distance from mine to railroad station is 25 miles. Two trips will be made daily, handling 150 tons. Hauling contract calls for delivery of 50,000 tons.

Shasta County

MAMMOTH COPPER (Kennett)—Construction of road from upper tram terminal to Friday-Lowden mine, owned and being developed by Mammoth company, has begun.

GREENHORN (Redding)—Property being developed by M. E. Dittmar under bond and lease and shipping 10 tons a day. Mine is situated four miles west of Tower House.

DREDGE LANDS ON CLEAR CREEK, south of Redding, owned by Gibson, Peterson, McMullen and other farmers, negotiated for by Lawrence Gardella of Oroville. Installation of dredge contemplated.

BELL COW (Redding)—This and other claims on Arbuckle Mountain near Ono have been secured under purchase option by Frank S. Greene of Ono. Glenn and Colusa men are interested with Greene. Thomas P. Ames will superintend development work.

Sierra County

RED LEDGE (Alleghany)—Quartz mill being installed by Barnhart & Hathaway of Nevada City, Calif.

MINER'S HOME (Howland Flat)—Gravel property which has long been in litigation to be reopened by W. C. Hendricks of Sacramento.

ORIENTAL (Alleghany)—Materials are being placed on ground and all preparations made to resume work by Croesus Mining Co. of New York. W. B. Pearson in charge.

BIGELOW (Sierra City)—To be reopened and ore extracted through No. 9 tunnel of Sierra Buttes mine which cut Bigelow ledge 20 years ago, when owners disagreed upon working terms and operation ceased.

Sonoma County

CULVER-BAER (Cloverdale)—Walter Smith and associates of San Francisco have taken bond and lease on this quicksilver mine. There are nine claims in group, embracing 1800 acres of land. Installation of machinery and furnaces is contemplated immediately. Exact terms of transaction have not been made public. Deal was made by Ida I. Davis of San Francisco.

Tuolumne County

JUMPER (Jamestown)—In 10 months that leasing system has been in operation, seven sets of leasers, totaling about 35 men, have taken out $10,000. The leasers pay royalty of 25%, and $1 a ton for milling. L. E. Grant is superintendent.

COLORADO

Boulder County

REPPY (Jamestown)—This molybdenum property has been investigated and explored by H. F. Linnenbrink and J. F. Scofield, of Pittsburgh, Penn., with encouraging results. The owners have decided to inaugurate development work on a larger scale.

Dolores County

RESOLUTE (Rico)—New company, eastern stockholders, has acquired holdings of M. T. Chestnut, of Denver. Chestnut claim was pioneer producer of rich silver ore.

Lake County

ROBERT E. LEE (Leadville)—This old Fryer Hill mine, producer of rich silver-iron ore, now outputs splendid zinc carbonite that constitutes main supply for local zinc works.

Park County

LONDON (Alma)—Numerous leasers who mined during past winter and spring are finally able to market their stocks of ore, wagon roads being now practically free from snow. Several four-horse teams are hauling over seven-mile road to Alma and returning with coal and other supplies for coming winter. This mine is on an isolated mountain, above timber line.

San Juan County

WILFLEY-MEARS MILL (Silverton)—Flotation equipment has been added to this plant which was erected to treat siliceous tails from old Silver Lake mill high up on mountain at mine. Last year flumes were built to convey tails from dump in lake, over precipice and down long slope to new mill along railroad and Animas river. Specially designed Wilfley tables, of unusual size and capacity were chief units in original installation.

San Miguel County

SMUGGLER-UNION (Telluride)—Ground has been broken for addition to mill at Pandora, anticipating increased production from Sheridan adit of Humboldt mine.

OPHIR RANGE GOLD (Ophir)—Prospecting and development operations are under way. Company has decided to remodel Suffolk mill and tramway preparatory to resumption of active operations. W. H. Staver is manager of enterprise and E. V. Davies will have charge of mill.

DELAWARE

Kent County

SOUTHERN ZINC & MINING CO. (Dover)—Has been incorporated with a capital stock of $1,000,000 to acquire and operate zinc mines. Incorporators are W. E. McCarthy, W. M. Pyle, and G. G. Stiegler.

IDAHO

Bonner County

IDAHO-CONTINENTAL (Porthill)—Fire of unknown origin completely destroyed mill, 26 miles from Porthill, July 30, entailing loss of $50,000. Plant was insured for $20,000. Compressor plant was located in mill, and this also was destroyed. The boarding house, storages and other camp buildings were in danger several times, but they escaped serious damage. President A. Klockman stated that he did not know if plant would be rebuilt, and that no decision would be reached until the directors met and canvassed situation, but it is believed that another concentrator will be constructed. There are 100 men employed at property.

Shoshone County

HYPOTHEEK (Kingston)—Plans and surveys being made for an aerial tramway.

SUCCESS (Wallace)—Gross earnings for July were $183,759. Operating expenses did not exceed $30,000, making estimated net earnings $150,000. It is believed that dividend rate will be increased to 8 or 10c. a share.

LUCKY CALUMET (Mullan)—Property includes 10 claims lying in Mullan copper belt between National and Snowstorm mines. Assessment has been levied and contract has been let for driving lower adit 500 ft. farther. Development in lower workings aggregates 4000 ft., at maximum depth of 1200 ft.

NORTHERN LIGHT (Kellogg)—No. 2 vein, recently tapped by crosscut from 200-ft. level and explored by shoot east and west drifts, is said to show more than foot of lead ore of good grade. B. G. Harmon, engineer in charge, will recommend to owners that shaft be sunk another 200 ft., in belief that mine will then be in position to maintain regular shipments.

H. E. M. (Wallace)—Hoped to have new 100-ton mill, for which machinery is arriving, ready to run by first of October. Ore will be delivered at mill, half-mile from tunnel portal, by electric haulage. Ore-shoot in No. 3 tunnel has been proved for length of 600 ft. Considerable ore was shipped from this level several years ago but expense of getting to railway precluded profit. Crosscut 2300 ft. long driven from Revenue Gulch side, cuts vein 400 ft. below No. 3 tunnel.

HECLA (Wallace)—Capital stock of company being unpaid to extent of $75,000 and considering it to be for best interest of stockholders that stock should become fully paid under laws of State of Washington, board of directors by unanimous vote levied assessment of 7½c. per share upon all capital stock of company of record July 28, 1915, and at same time declared special dividend of 7½c. a share on same stock. Each stockholder of record of that date has been charged with assessment and credited with dividend, account thereby being balanced and closed.

MICHIGAN

Copper

MOHAWK (Mohawk)—Notwithstanding bonuses paid and maintenance of normal scale of wages, cost of rock production has been reduced 30c. since last year. This showing is particularly creditable to improvements in operations.

NEW ARCADIAN (Houghton)—Second test-rock shipment is showing closer to 40 lb. than 30, in mineral, according to rumors which cannot be verified. South drift on 900 level is in good ground. On upper level, closest to New Baltic, has been found best rock of all, less than 60 ft. from line.

ONONDAGA (Houghton)—First drill is in ledge. Will locate individual beds on Nonesuch lower rim. Doctor Lane, formerly Michigan state geologist, is working with President Pryor in geological analysis of situation and R. C. Allen, state geologist, is expected here soon on similar work.

CALUMET & HECLA (Calumet)—Maintained higher rock tonnage during July than in June, and June was best record in history of property, notwithstanding fact that tailings and regrinding plant was put out of commission by short-circuiting about middle of month.

ISLE ROYALE (Houghton)—Now has No. 7 shaft down to bedrock. This has been one of most difficult tasks of kind ever put through in this district. No. 1 shaft now is timbered down below twelfth level. Men say that there is enough broken rock there more than enough to repay for reconstruction of this shaft.

Iron

BAKER (Iron River)—Work has been resumed after idleness of over one year. Ore hoisted is being shipped.

BENGAL (Iron River)—Mine has entered shipping column; 80 men are now employed.

MARY CHARLOTTE (Negaunee)—About 100 new hands have been added here. Mine is producing to capacity. All of ore that can be got out has been sold. Other Breitung mines are also working strong.

WARNER (Amasa)—Pickands, Mather & Co. will explore this old property. Water is to be removed from workings. New headframe has been erected. In case sufficient ore is found, machinery from Hemlock, close by, will be transferred. Hemlock was closed several months ago.

IRONWOOD—Heavy shipments are being made from Gogebic range. All mines are shipping strong. Chicago & Northwestern railway handled 200,000 more tons up to Aug. 1, than for same period last year. Newport mines will ship about 1,000,000 tons. Oglebay, Norton & Co. will move everything in stock. Steel Corporation is working almost to capacity. It is predicted that range shipments will equal best year in past. Gogebic will be ahead of Menominee and Marquette ranges for year, as latter two are just hitting their stride now.

MINNESOTA

Duluth

MINNESOTA STEEL (Duluth)—Eleven hundred men at work rushing completion of steel plant and cement plant. Additional men being employed at rate of 25 daily, preference being given to Duluth residents. At Morgan Park, the model city, street and public work being pushed vigorously. Hospital and large office building planned.

Mesabi Range

GLEN (Chisholm)—After being idle two years, mine active. Underground operations being extended rapidly. Shipments total 75 cars daily.

QUINN-HARRISON (Nashwauk)—First ore was put through washing plant last week. Mine is working two shifts. About 250 men are employed.

MAHONING (Hibbing)—Orders have been received to ship 2,600,000 tons of ore from here this year. Thus far about 800,000 tons sent out. Largest shipping year for mine was 1907, when 1,564,000 tons was shipped.

CROSBY (Nashwauk)—Cleveland-Cliffs Iron Co. has commenced construction of its concentrator. Waste material will be washed from ore, making it more saleable. Large dam has been built across stream to afford water supply. Ore will be shipped late in season.

ELBA (Elba)—Three 8-hr. shifts are now being worked. Corsica, which is worked in conjunction with Elba, is operating with two shifts. High-grade bessemer ore is being shipped. New timber shaft is being sunk at Corsica. Main shaft is being deepened 75 ft. Another orebody lies underneath one now being worked.

VIRGINIA—Over 400 Serbians, Montenegrins and Bosnians left Mesabi range last week for Winnipeg, Can., to join small army of 9000 men which were transported to Europe by the British government. Men were from Chisholm, Hibbing and Virginia district. Further departures are apt to cause shortage of miners. Plenty of common laborers, but miners are scarce.

MONTANA

Deer Lodge County

GEORGETOWN MINING DISTRICT—Fred Tuescher who has a lease and bond on Marguerita claim and on Gold Coin group has uncovered ore of Marguerita that is assaying $14 a ton in gold. Klaus and Fliegler, who have lease on Butte and Anaconda Consolidated properties, are doing considerable development work.

Fergus County

KENDALL (Lewistown)—One section of old Kendall mill at Lewistown has recently resumed operations after shutdown of several years. Within short time other sections of mill will go into commission. Part of Kendall mine was leased some time ago to several miners after it was discovered that big orebody in North Mocassin of Barnes King extends directly into Kendall ground. There are now 25 miners drifting towards North Mocassin body; 10 others are engaged in getting ore from opencut.

Lewis and Clark County

DISTRICTS TRIBUTARY TO HELENA—Rosenfield brothers and associates, who have bond and lease on Bert Lathrop property in Mitchell Gulch, have cut lead in their shaft 3 ft. wide carrying copper sulphide and gold, assaying $30 to $400. Several carloads have been shipped to smeltery. At head of Ten Mile Creek, 25 miles southwest of Helena, 10-stamp mill of James Breen is running regularly on ore from porphyry dike, said to average $3 per ton. It is mined from opencuts and trammed directly to mill. It is rumored that the Anaconda company experts have been examining the dike property and making investigations regarding the water supply. It is said that if water question can be settled satisfactorily, Anaconda company may take over the porphyry dike and establish a large milling plant. The Valley Forge property in that district is one of the best developed mines and has a tunnel nearly 3000 ft. long that cuts lead at depth of 900 ft. below surface. Two cars of ore a week have been shipped from property for many months. In Scratch Gravel district, Huffaker & Hill are steadily at work on Eastern Bell mine which they bonded from Helena mining bureau. Spokane-Butte-Helena syndicate, which is developing extension of Franklin Dead, has drifted east and west of shaft and found lead continuous and containing ore of commercial value. In Bald Butte section of Marysville district, old Bald Butte mine, which paid $1,500,000 in dividends, is in fair way to repeat its former record. Crosscut to new rich streak of ore is almost completed. Bald Butte mine is thoroughly equipped. Mill and power plant are in first-class condition. Helena mining bureau has installed machinery and unwatered 100-ft. shaft of Silver King mine near Clancy. Crosscutting to lead is now in progress.

Mineral County

WILSON MINING & SMELTING CO. (Saltese)—Company is developing two groups of claims on Silver and Big Thunder Creeks, about two miles from Saltese. Claims said to be promising. One group consists of six claims on lead and silver vein which is developed by two tunnels 200 and 300 ft. long. Other group consists of eight claims on which several tunnels and crosscuts have developed rich shoot of copper ore. William Burk of Saltese is president of company.

Silver Bow County

RAINBOW LODE DEVELOPMENT (Butte)—The financing of this company has been completed and funds are now in sight for resumption of operations, a mortgage for $400,-

000 on the company's properties having been filed July 6 with the county clerk. Principal property is the Butte & London mine which it is the intention to develop with the new funds.

NEVADA

Esmeralda County

GOLDFIELD CONSOLIDATED (Goldfield)—Estimated production for month of July, 33,200 tons; gross extraction, $275,000; operating expenses, $170,000; net realization, $105,000.

ATLANTA (Goldfield)—Experiments now being conducted with oil flotation on low-grade Atlanta ores in Goldfield Consolidated mill. Reported that 89 ore is being treated at a profit.

CHAMP d'OR FRENCH GOLD (Goldfield)—Jean Pierre Charra, of Paris, France, consulting engineer, who has been in Goldfield for several months looking after interests of company in southern Nevada, today announced sale of local plant, known as French mill to Elmer E. Clapp, of Boston, Mass. Mr. Charra also announced that William Dunphy has been granted two-years' lease on company's Orleans property in Hornsilver district and Nicholas Theo lease of like duration on its holdings in Tokop district.

Nye County

TONOPAH ORE PRODUCTION for week ended July 31 amounted to 10,407 tons valued at $213,286, compared with 11,137 tons week previous. Producers were: Tonopah Belmont, 3382 tons; Tonopah Mining, 2200; Tonopah Extension, 1860; West End, 1002; Jim Butler, 1100; Montana, 107; and Midway, 56 tons.

TONOPAH EXTENSION (Tonopah)—Injunction granted against the West End Co. until Sept. 1, when modifications will be made permitting the West End Co. to continue work on California vein, subject to inspection of plaintiff company and supervision of court, in apex litigation over Egyptian and California veins.

Storey County

JACKET MILL (Gold Hill)—Received 1043 tons dump rock and shipped one bar of bullion to smeltery.

COMSTOCK PUMPING ASSOCIATION (Virginia)—Cut drain and laid track and sills on 2700 level of Mexican.

OPHIR (Virginia)—At Central tunnel tramway and rock-breaker installation completed. Mill bins are being filled.

UNION CONSOLIDATED (Virginia)—West crosscut on 2650 level in porphyry and quartz; north drift on 2500 level reopened.

OPHIR AND CON. VIRGINIA (Virginia)—On 2500 level reached winze and will equip station for operating below 2700 ft., in east vein.

BELCHER (Gold Hill)—Raise on 1300 level and stoping of mill rock started. Mill rock also saved from Crown Point northeast crosscut. Water being successfully lowered.

MEXICAN (Virginia)—From 2300-level understope 37 tons taken averaging $6. West crosscut 2700 level is in porphyry and quartz stringers of low assay value. Comstock drift on 2500 level has been reopened total of 550 ft.

NEW JERSEY

Sussex County

NEW JERSEY ZINC (Franklin Furnace)—Sussex County Board of Taxation has issued instructions to make substantial increase in assessment of property of New Jersey Zinc Company, in Franklin Borough. Board believes that present assessment of $2,025,000 is not as large as it should be. Board is of opinion that valuation is too low, and has been for several years, although it was fixed by State Board. Zinc company declared stock dividend of 250%, capital stock increased from $10,000,000 to $35,000,000. It is reported that Assessor of Ogdensburg Borough, has also been ordered to make increase in Zinc Company's assessment in that Borough.

NEW YORK

Saint Lawrence County

NORTHERN ORE (Edwards)—Completed its new mill last spring and for last few months has been making commercial shipments of blende. About carload of concentrates is going out of Edwards each day, an output that can be maintained readily enough from mine now worked which is opened to depth of 500 ft. In addition to this mine, company has second shaft nearby which has not been placed in production although opened in good body of ore; besides it controls under ownership or lease a large acreage that shows more or less mineralization.

TENNESSEE

Polk County

TENNESSEE COPPER (Copper Hill)—Plans being made for large additions to acid plant. Arrangements have been made with International Agricultural Corporation, which now has contract controlling sulphuric-acid output of Tennessee company whereby benefit from increased acid output to be sold to Allies will be shared mutually.

UTAH

Beaver County

SOUTH UTAH (Newhouse)—Ore at this property has been difficult to treat; and investigations are now under way with view to finding suitable treatment for large accumulations of tailings, as well as for ore in mine.

MOSCOW (Milford)—July output was unusually large, amounting to 17 cars of first-class ore valued at about $25,500. New shaft has been sunk 1000 ft. in past year, and ore has been opened in new ground. Production at rate of 10 to 12 cars monthly has been kept up throughout work.

PALOMA GOLD & SILVER (Milford)—Eight inches of high-grade lead-silver ore have been opened in shaft which is being sunk to reach downward extension of ore, developed to south. Shaft has been sunk 300 ft. on incline following contact of limestone with monzonite. Fissures occur in limestone south of shaft, mineralized with iron, silver and lead.

Juab County

TINTIC ORE SHIPMENTS for week ended July 31 totaled 163 cars, estimated at $150 tons valued at $200,000, compared with 193 cars last week. There were 19 shippers.

RIDGE & VALLEY (Eureka)—Shipments were resumed at this property, week ended July 30. Mine has not been worked on company account for some time, though leasers have made shipments. Both lead and zinc ore are being mined on the 1650 level.

Salt Lake County

MICHIGAN-UTAH (Alta)—Arrangements are being made to resume work at this property, which at present is being largely worked by leasers.

MONTANA-BINGHAM (Bingham)—Streaks of ore carrying copper, silver and some gold have been cut in main tunnel, which is now in over 3900 ft.

LAST CHANCE (Salt Lake)—Work to be started at this property in Big Cottonwood, west of Cardiff. Location is one of oldest in district. F. O. Horne, James Hauerbach et al. are interested.

ALTA CONSOLIDATED (Alta)—Silver-copper ore, 12 in. in width is still exposed in face of No. 2 east drift, 345 ft. east of raise from main tunnel level. Braine fissure has been opened for total distance of 675 ft.

SOUTH HECLA (Alta)—New ore has been opened in Kate Hays fissure on east side of property. Development in this section is being done from Quincy tunnel. Ore on 250 level is producing most of shipping product, which at present amounts to 40 tons a day. Two shifts are working on 500 in driving for Wedge oreshoot on this level.

CARDIFF (Salt Lake)—Shipments amounting to 3420 tons have been made since orebody was cut in lower tunnel last October. These brought $145,350. Fifty-five teams are hauling at present, and upwards of 100 tons a day are being shipped. New boarding house and other surface improvements have been practically completed. Electric power line is built nearly to camp.

BINGHAM-EMPIRE (Provo)—This company was incorporated July 31 for development of property in Bingham district. Capitalization is $10,000 divided into shares of 1c. each. Jesse Knight holds 510,000 shares. There are 484,000 shares in the treasury. Incorporators and directors are: Jesse Knight, president; A. M. Knight, W. L. Mangum, K. S. Jordan, G. A. Storrs, E. G. Jensen.

Tooele County

THERE IS MUCH ACTIVITY IN DRY CAÑON near Stockton. More men are being worked, and more ore shipped than at any time during past five years. Mono, under lease to R. C. Ferguson, is shipping lead-silver-copper ore. Big Four Exploration Co. is making regular shipments of zinc ore from its lease on Queen of Mills; copper and silver-lead ore is being developed. Lynch and Travis lease on Hidden Treasure is working 25 men, and making shipments. Dry Cañon Consolidated is extending its long tunnel in mineralized ground. Leasers are working on Utah Queen, Big Lead, Wandering Jew, and Thad Stevens claims; and most of them are breaking ore.

IN SILVER ISLAND DISTRICT near Wendover active work is being done at Utah-Wyoming, Hole in the Wall, and Wendover Wonder properties.

PROMONTORY POINT (Ogden)—Articles of incorporation prepared by Ogden men for company to work group of 35 zinc claims on Promontory Point. Those interested are: A. S. Condon, C. A. Boyd, D. C. Lawson, G. W. Green, D. Marshall, A. Smith, R. E. Boyd, and George Barry.

WISCONSIN

Ashland County

CHARCOAL & IRON CO. OF AMERICA (Ashland)—Blast furnace resumed operations Aug. 1 after idleness since May, 1913. Formerly controlled by the Lake Superior Iron & Chemical Co.

SOUTH AMERICA

Chile

CHILE COPPER (Chuquicamata)—Is now treating between 4000 and 5000 tons daily. Full capacity of 10,000 tons will not be reached for several months.

BRADEN (Rancagua)—During June mill treated 91,029 tons of 2.10% ore, produced 7249 tons concentrates, 19.37%. Minerals separation treated 88,633 tons of 1.71% tailings making 19.94% concentrate. Copper produced 1271 tons.

AFRICA

Belgian Congo

TANGANYIKA CONCESSIONS (Katanga)—Produced 13,-$64,000 lb. of copper during first half of 1915. This compares with 21,444,000 lb. turned out in 1914, and 30,000,000 lb. made in 15 months ended Dec. 31, 1913. It has been difficult, as well as costly to get mine product from several hundred miles inland to coast, and thence to England for refining and market. Last year company operated two furnaces; increase up to June last was due to blowing in of third furnace. Two more furnaces, each with 30% to 35% greater capacity than those now in operation, are expected to be placed in commission by end of 1915, making possible 50,000,000 lb. production in next year. More than $25,000,000 said to have been spent in development and equipment to date.

Rhodesia

GOLD PRODUCTION OF RHODESIA in June was 57,269 oz., being 859 oz. more than in May, and 624 oz. more than in June, 1914. For the six months ended June 30 the total was 401,817 oz. in 1914, and 438,740 oz. in 1915; an increase of 36,839 oz. Other metal production for the six months was 87,140 oz. silver; 1633 tons copper; 15 tons lead. Output of other minerals was: Chrome ore, 22,079 tons; asbestos, 514 tons; coal, 184,062 tons. There were also 71 carats of diamonds reported.

The Market Report

Metal Markets

NEW YORK—Aug. 11

All of the principal markets declined sharply during the last week, lead and spelter exhibiting something akin to demoralization.

Copper, Tin, Lead and Zinc

Copper—At the beginning of our week of record, producers made small sales at 18c., regular terms, but customers were few and far between, and sharp concessions in price were made in order to attract business; but buyers scenting the situation were coy. A bid of 17½c., regular terms, was declined on Thursday. Later when the producer wanted to accept it, the buyer declined. During the second half of the week, sales were made at 17½c., regular terms. Export orders were taken which probably will net less, but in view of the conditions of freight, insurance, exchange, etc., it is impossible to reckon what the sales will net until they are settled for. Some of the principal producers are out of the market, or are maintaining a nominal asking price above the market and covertly soliciting bids.

The inquiries upon which such great hopes were based a week ago failed to materialize in business. It is believed that they still exist potentially, some new and large ammunition orders having been placed. However, the ammunition manufacturers are apparently taking more time for covering their metal requirements than they did a little while ago. At the close copper was freely offered at 17½c., regular terms, or about 17.35c., cash, New York.

The great demand upon electrolytic refinery capacity is evidenced by the fact that $20 per ton has been paid for refining in some recent blister-copper contracts.

Copper Sheets bring 24@25c. per lb.; no base quotations are made by the principal maker. Wire is quoted at 19½@20c. per lb., carload lots at mill.

Visible Stocks of Copper in Europe, July 31 are reported as follows: Great Britain, 23,959; France, 5554; afloat from Chile, 1900; afloat from Australia, 3700; total, 35,113 long tons, or 78,653,120 lb.; an increase of 2195 tons over the June 30 report.

Tin—The unfavorable political developments caused a decline in price in the early part of the week. Sellers in the East refused to meet the lower prices. Learning this, buyers came in at the lower level and toward the close there was a rally.

Lead—Throughout the week producers were trying to find a level at which buyers would become interested, but met with no great success. The A. S. & R. Co. reduced its price from 5c. on Aug. 7 to 4⅝c. on Aug. 9, and to 4½c. on Aug. 10. At all times previous to the last cut, independent producers offered to sell at ¼c. below the A. S. & R. Co.'s price, but it seemed as if lead would have to be given away in order to interest anybody in taking it. On Aug. 10 sales were made at 4.45c. which lent encouragement in the idea that the market might be beginning to steady itself.

Spelter—This market declined steadily throughout the week and showed all the earmarks of demoralization. Speculators who wanted to liquidate, manufacturers who had overbought and wanted to resell, and the weaker producers exerted pressure, all of these factors contributing to the sharp decline, which, however, did not result in much business being done. On the other hand, there were some producers who are not trying to sell, being firm in the belief that they are going to see 25c. spelter once more.

It is estimated by one smelter that the production of high-grade intermediate spelter by distillation of prime western is going on at the rate of 3000 to 4000 tons per month.

Butte & Superior's production of blende concentrates in July was 13,000 tons.

Zinc Sheets are in good demand and sales are steady. The base price is $21 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Usual extras are charged.

Nickel—There is no change, although demand is very good. Ordinary forms are 45@50c. per lb., according to size and terms of order. Electrolytic is 3c. higher

Other Metals

Aluminum—Business has been on a fair scale and the market is firmer. Quotations are 32@34c. for No. 1 ingots, New York.

Antimony—The market has been very quiet, with hardly more than a retail business doing. Ordinary brands sell at 35@36½c. per lb. Cookson's is nominal at 48@50c. per lb., with few sales.

Quicksilver—Business has been rather quiet, though prices remain strong. New York quotations are $92@94 per flask of 75 lb. for large orders, with $95@98 for small lots. San Francisco reports by telegraph a weak market, with $87.50 @90 per flask quoted. London price is £18 2s. 6d. per flask, with £18 named from second hands.

DAILY PRICES OF METALS IN NEW YORK

*Nominal.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York, 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

Aug.	Silver	Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
		Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts per Lb.
5	22⅜	71⅛	75⅛	87½	18 64	154¼	155¼	23 5/16	5 02	85	18 10
6	22 3/16	71⅛	73⅛	86½	18 43	151⅜	153¼	23 3/16	4 94	75	15 97
7	22 3/16	.	.	.	.	.	.	.	.	.	.
9	22 5/16	69½	70⅛	84½	17 99	150	152¼	22⅞	4.84	70	14.90
10	22⅛	69	70¼	83¼	17 73	151	153	21⅞	4 65	67	14 27
11	22 5/16	68⅛	69⅛	83¼	17 73	152	154¼	20 11/16	4.40	65	13 84

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80: £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Gold, Silver and Platinum

Gold—The largest shipment on record reached New York Aug. 10. The total value was $52,000,000, of which $35,000,000 was in gold, the balance in securities. It was brought from Liverpool to Halifax on a warship, and from Halifax to New York on a special train.

Platinum continues quiet, but rather steady. Business is on a moderate scale only. Current quotations are $37@39 per oz. for refined platinum, $41@44 per oz. for hard metal.

Silver—The market has shown more activity and strength this week on London buying for India account, advancing to 22⅞d. Orders for the present being filled the price has reacted to 22⅝d. The New York price has been adversely affected by the fall in sterling exchange, demand bills closing at 4.74¾. The silver market shows no decided tendency.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Aug. 7

The base price paid this week for 60% zinc ore was $100 per ton, down to $95 at end of the week. The base price paid for 80% lead ore was $56 per ton.

SHIPMENTS WEEK ENDED AUG. 7

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Year	111,013,270	4,083,160	16,689,950
Week	3,112,690	.....	773,500

Shipped during week to separating plants, 3,783,890 lb. zinc ore.

JOPLIN, MO.—Aug. 7

Blende, high price, $102; base price per ton of 60% zinc, premium ore, $100, medium, $95@86; lower grades down to $75; calamine, base per ton of 40% zinc, $48@56. Average, all grades of zinc, $93.73. Lead, high price, $60; base, $60@50 per ton of 80% metal content; average, all grades of lead, $58.30 per ton.

SHIPMENTS, WEEK ENDED AUG. 7

	Blende	Calamine	Lead	Values
Totals this week	11,831,050	63,740	2,038,050	$616,870
Totals this year	344,657,710	28,376,510	52,520,930	15,034,890

Blende value, the week, $555,730; 32 weeks, $13,019,810.
Calamine value, the week, $1730; 32 weeks, $616,550.
Lead value, the week, $59,410; 32 weeks, $1,398,530.

Iron Trade Review

NEW YORK—Aug. 11

The demand for finished steel products, both for home use and for export continues heavy. The export calls are rather urgent in some cases.

Pig Iron Production in July again showed an increase. The reports of the furnaces, on Aug. 1, as collected and published by the "Iron Age," show a total of 234 coke and anthracite furnaces in blast, having a total daily production of 86,800 tons; an increase of 6400 tons over July. Making allowance for the charcoal furnaces, the total make of pig iron in the United States in July was 2,593,000 tons; for the seven months ended July 31 it was 14,826,800 tons. Of this 10,840,450 tons, or 73.1% of the total, were made by steel-works furnaces.

The United States Steel Corporation reports its unfilled orders on July 31 at 4,928,540 tons, an increase of 250,344 tons over June 30, and of 1,091,897 tons over Dec. 31, 1914.

PITTSBURGH—Aug. 10

The steel market has been somewhat quieter the past week, as to new commitments, but specifications against contracts are as heavy as ever, and the mills as a rule are piling up shipping orders despite the fact that their production is a shade heavier. Departments recently placed in operation are turning out somewhat more tonnage and when cooler weather arrives still larger tonnages are to be expected. Practically the entire openhearth steel making capacity is active, and the mills have been so active in recent weeks in securing consent to ship bessemer steel in place of openhearth that there is considerably more bessemer capacity in operation and this branch may soon be operating at capacity also.

The scrap and pig-iron markets have become very much excited. Heavy melting steel scrap has sold at $15, delivered Pittsburgh, representing an advance of over $1 a ton in a week and of fully $3 a ton in 30 days, and dealers look for still higher prices. Pig iron has been advancing in nearly all markets, but more sharply in this district than elsewhere, and predictions are freely made that within two or three months pig iron will be several dollars a ton higher than at present.

Steel prices are continually firming up. Bars are likely to advance above 1.30c. very shortly, while plates are firming up to that level. Sheets have continued to advance, and are now 1.85@1.90c. for black, but galvanized have been weakening with the decline in spelter. An advance in wire products, from $1.60 basis for nails, is predicted to occur before September.

Pig Iron It is claimed that basic iron has sold at $14, Valley, and bessemer at $15, Valley, while there are no quotations to be found below these figures. These prices represent advances of over $1 a ton in less than a month. Foundry iron has stiffened steadily, with moderate transactions on the way up. The market is quotable as follows: Bessemer, $15; basic, $14; foundry, $13.50; forge, $13.25; malleable, $13.50, at Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese Official statistics of imports of ferromanganese in the first quarter of this year, just published, show only 585 tons imported in the three months. There is now no regular contract market, importers having to submit all inquiries to the English producers. The prompt market remains at $100@105, Baltimore, for small lots.

IRON ORE

Shipments of iron ore from the Lake Superior region in July were 7,204,020 tons, being 1,419,506 tons more than in July, 1914, but 1,000,396 tons less than in July, 1913. For the season to Aug. 1 the shipments are reported by the "Iron Trade Review" as below:

Port.	1914	1915	Changes
Escanaba	1,740,741	2,062,700	I. 321,959
Marquette	681,361	1,114,360	I. 432,999
Ashland	1,416,825	1,870,077	I. 453,252
Superior	5,690,413	3,064,002	D. 2,626,411
Duluth	2,949,286	6,710,460	I. 3,761,174
Two Harbors	2,930,004	3,903,704	I. 973,700
Total	15,408,630	18,725,303	I. 3,316,673

The heavy decrease at Superior and the large gain at Duluth result from the cessation of mining on the Hill leases, and the transfer of activity to the old Mesabi mines.

The Toto iron mines now being developed by the Bethlehem-Chile Iron Mines Co. will probably send to the Bethlehem Steel Works in the United States about 200,000 tons of iron ore this year, and it is expected that the quantity next year will approximate 1,000,000 tons.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 377,410 short tons; shipments, 373,182 tons. Production of Greensburg and Upper Connellsville districts was 45,322 tons.

Anthracite Shipments in July were 4,934,205 long tons, being 457,652 tons less than in July, 1914. For the seven months ended July 31 the total shipments were 38,337,646 tons in 1914 and 36,529,509 in 1915; a decrease of 1,808,137 tons, or 4.7%. Of the shipments this year 31,544,935 tons, or 86.4% of the total were buckwheat No. 1 and larger sizes; 4,984,574 tons, or 13.6% being of sizes below buckwheat No. 1, or steam coal.

Chemicals

NEW YORK—Aug. 11

The general market is not especially active, but there is a fair business doing in many lines. In heavy chemicals trading is rather slow.

Arsenic—Demand continues about as usual, on a moderate scale. Prices are unchanged at about $4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is steady and prices are about the same. Quotations are $7.25 per 100 lb. for carload lots and $7.50 per 100 lb. for smaller parcels.

Nitrate of Soda—Trade in this article is good for the season. A moderate business is forward and prices are steady. Quotations are 2.35c. per lb. for all positions this year.

Magnesite—According to information received from the U. S. consul at Athens, dated July 10, 1915, magnesite, crude and calcined, has been added to the embargo list of Greece.

Pyrites—Imports at Baltimore for the past week included 16,442 tons iron pyrites from Spain.

PETROLEUM

The monthly statement of the "Oil City Derrick" shows new oil wells opened in July as follows: Pennsylvania grade, 356; Lima-Indiana, 40; Central Ohio, 45; Kentucky, 10; Illinois, 64; Kansas-Oklahoma, 320; Texas-Louisiana, 147. The total number was 982 wells, the new production amounting to 133,773 bbl. The larger increase was in Louisiana. At the close of July there were 1612 wells under drill and 405 rigs going up.

Assessments

Engineering and Mining Journal

VOLUME 100 AUGUST 21, 1915 NUMBER 8

The Wisconsin Zinc District—I

By H. C. George*

SYNOPSIS—The zinc district, usually called after Wisconsin, in which state it principally occurs, includes also parts of Illinois and Iowa. It was opened as a lead producer in 1822. The production of both lead and zinc is shown. Geology of the district is described, together with the origin of the ores.

The Wisconsin zinc district, or the Upper Mississippi lead and zinc district, as it is often called, lies in the southwestern corner of Wisconsin, in Grant, Iowa and Lafayette Counties, and it includes adjoining parts of Illinois and Iowa.

The district is about 70 miles long from north to south and about 40 miles wide. It lies wholly within what is geologically known as the nonglaciated area of the upper Mississippi Valley.

History of the District

The district was first opened as a lead producer in 1822. From this time until 1860 about 205,000 tons of cog lead (galena) and washed lead (galena) was produced from shallow crevices and openings. From 1860 to 1900 about 74,500 tons was produced, and since that time from 5000 to 7000 tons has been produced annually. Since 1900 most of the lead concentrates produced have been as a byproduct of the zinc mines.

The first zinc was mined about 1862, and was from the carbonate ores locally known as "drybone." Very little blende was mined in the district previous to 1875 and that mined from 1875 to 1900 was mostly of the high-grade, hand-cobbed, sheet-ore class, which usually contained from 45 to 60% metallic zinc. Such mines as the Sallie Waters, Quinlin, Lead Mine, Benton Blende and Ida Blende, all near Benton, Wis., were mines which produced ores of this period. The mines located at Highland, the Coker Mine at Livingston, Wis., and the Opencut Mine at Shullsburg, Wis., were heavy zinc-carbonate producers previous to 1900.

The production of zinc ores in the district from 1862 to 1890 was about 283,500 tons, mostly zinc carbonate, with a probable average zinc content of 30%. From 1890 to 1903 the production of the district consisted of about 126,000 tons of hand-cobbed and hand-jigged zinc carbonate and blende.

FOX MINE, MILL AND TAILING HEAPS, HAZEL GREEN, WIS.

During the last few years of the nineteenth century there was a decline in the production of both lead and zinc ores in the district. Since 1903 the revival of the district as a producer of blende, and incidentally zinc carbonate and lead, has taken place as a result of the advance in the price of lead and zinc ores. Beginning with that date modern methods of mining and milling

TABLE OF LEAD PRODUCTION FROM MINES

Year	Tons of Lead Concentrates
1822 to 1860	205,000
1861 to 1900	74,500
1901 to 1914	74,000

*Chief engineer, Wisconsin Zinc Co., Platteville, Wis.

lead and zinc ores with power machinery have placed the industry on a stable basis. Nearly all of the district production consists of concentrates containing mixed zinc and iron sulphides with an average zinc content of about 35%. The magnetic separation of low-grade roasted blende concentrates has greatly broadened the field of operations. Zinc concentrates ranging in metal-

TABLE OF ZINC PRODUCTION FROM MINES

Year	Tons of Zinc Concentrate	Year	Tons of Zinc Concentrate
1862 to 1890*	283,500	1909‡	75,528
1891 to 1903†	126,000	1910‡	102,070

lie zinc content from 20 to 40% are roasted, the iron sulphides magnetized and removed magnetically and a finished blende is produced which will assay from 58 to 61% metallic zinc.

FIG. 1. MAP OF THE WISCONSIN ZINC DISTRICT

General Geology

The strata of the district consist of a series of Silurian and Ordovician limestones, shales and sandstones, underlain by Cambrian sandstones and pre-Cambrian crystalline rocks. A typical section would be:

		Feet
Silurian	Niagara limestone	50
Ordovician	Maquoketa shale	160
	Galena limestone	230
	Platteville limestone	55
	St. Peter sandstone	70
	Lower Magnesian limestone	200

Erosion has exposed all of these formations in some parts of the district. Nearly all of the Niagara and Mequoketa formations have been eroded away. The Platteville, Belmont and Sinsinawa Mounds in Wisconsin and the numerous mounds in northwestern Illinois are all that remain of this formation in the district.

There is an east-west unbroken ridge in the northern part of the district known as Military Ridge. A north-south ridge extends from it through the middle of the district for a distance of about 30 miles. It is along these two ridges that the local branch of the Chicago & Northwestern R.R. is built. The formations exposed on them are the upper part of the Galena limestone and the lower part of the Mequoketa shale. The ground slopes north and south from the east-west ridge and east and west from the north-south ridge to drainage basins. The streams located in these drainage basins have cut down through the formations, so that at various points along their courses the Platteville limestone, the St. Peters sandstone and the lower Magnesian limestone formations are exposed.

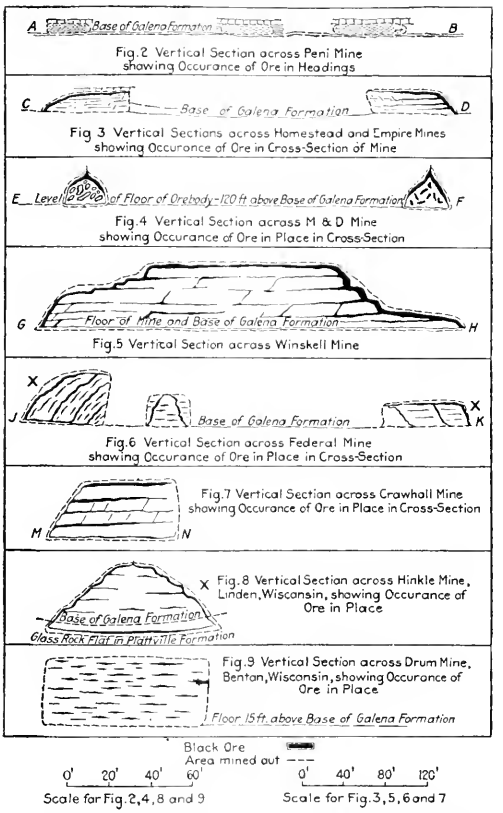
The rock formations of the district dip to the south-southwest, descending about 20 ft. per mile. The strata have been compressed and folded slightly, producing a series of synclines and anticlines and structural basins. The main axis of most of the basins is east and west, produced by lateral pressure from the north and south. The secondary axis of the basins is north and south, produced by an east and west lateral pressure. Frequently one leg of the synclines or one side of the basins will dip more steeply or show changes in slope. At these points the orebodies usually occur, in either the lower part of the Galena or the upper part of the Platteville formations, or in both.

The Galena formation consists of heavily bedded dolomites, interbedded with chert beds, nodules and thin-bedded clay shales. The base of the formation consists of thin-bedded brown carbonaceous shales from one to 15 ft. in thickness. These shales are known as the "oil rock." The bottom of this shale marks the base of the Galena limestone formation. A blue clay shale usually occurs immediately below the oil rock. This shale varies from a few inches to 6 or 7 ft. in thickness and is known as the "clay bed." Immediately below the clay bed is the "glass rock," a fine, compact limestone, usually gray or brown in color, which breaks with a conchoidal fracture, from which characteristic it derives its name. At some places there are shale beds resembling the oil rock between the clay bed and the glass rock. At other places there is practically no oil rock, and at still others there is no clay bed. The base of the glass rock marks the base of the ore-bearing formations as worked up to the present time; but recent discoveries made at the Winskell mine, east of New Diggings, Wis., indicate that ore in paying quantities occurs in the Platteville limestone nearly down to the top of the St. Peter sandstone. The

lower part of the Platteville limestone formation consists of thick-bedded dolomites similar to those of the Galena limestone formation.

The general supposition is that the ore has been dissolved out of the Galena limestone and the overlying Mequoketa shale, in which it is found, and deposited in the crevices and openings existing in the lower part of the Galena limestone and the upper part of the Platteville limestone in the structural basins.

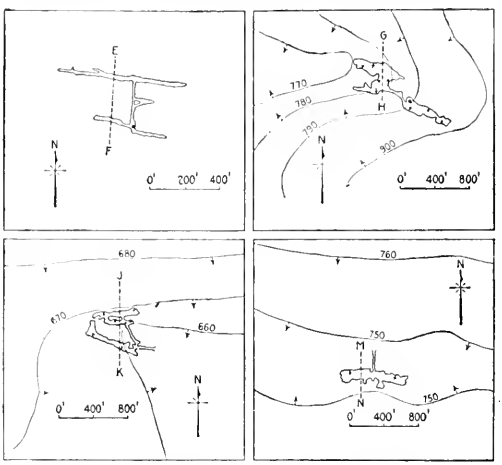
The crevices and openings in which the ore occurs may have been produced in several ways. The lateral pressure and the resulting folding may have produced them, or the dolomite beds for several feet immediately



FIGS. 2 TO 9. SECTIONS OF VARIOUS WISCONSIN MINES

above the impervious oil rock may have been dissolved out along channels in the structural basins, producing a slump in the overlying strata. Or as suggested by H. Foster Bain, the oil-rock layer, containing much organic matter, being much thicker in certain parts of the structural basins, has decreased in thickness to a considerable degree during the changes it has undergone, in the same manner that coal beds have decreased in thickness, producing slumps in the overlying formations at points where the oil rock is the thickest.

Erosion, ground-water level and the physical and chemical differences of the formations in which the orebodies occur have produced different types of ore deposits. Fig. 16 shows a vertical cross-section from the Mequoketa shale to the base of the glass-rock formation. All of the known orebodies of the district occur at some horizon in this vertical section. If the orebody occurs at points marked *A*, *B* or *C*, it will be of the types shown in Figs. 4 and 10. If the orebody is above ground-water level, the ore will consist of galena as "cog lead," zinc carbonate or blende, or all of these minerals occurring together. This type of orebody is known locally as a "crevice" or an "opening." Practically all of the lead mined in the district previous to 1900 was secured from orebodies of this type. Recently such mines have been worked below ground-water level. Such mines are the



FIGS. 10 TO 13. TYPICAL WISCONSIN OREBODY PLANS

Fig. 10 (upper left)—M & D Mine, Cuba City, Wis. Fig. 11 (upper right)—Winskell, New Diggings, Wis. Fig. 12 (lower left)—Federal Mine, Hazel Green, Wis. Fig. 13 (lower right)—Crawhall Mine, New Diggings, Wis.

Board of Trade, the Wicklow and the M & D, at Cuba City, Wis.; and the White Rose and Merry Widow, west of Galena, Ill. Orebodies of this type are frequently rich but limited in production. They are supposed to have been formed in the following manner. Certain rock strata at a given horizon are dissolved for a short distance on both sides of a vertical crevice, and the opening is simultaneously, or later, filled with lead and zinc ores chemically deposited.

If the orebody occurs at points marked *D*, *E* and *F*, Fig. 16, and is not the upper part of an orebody which extends to a lower level, it is frequently of the type shown in Fig. 9—a vertical cross-section of the Drum mine, east of Benton, Wis. In this type of orebody there are no distinct sheets of blende. The ore is disseminated, or "sprangled." In other words, the ore exists as small gash veins. Orebodies of this type have never been of much importance or long-lived. They are locally known as "bunches," occurring where a series of crevices cross at right angles.

The important mines of the district are those that occur in the lower part of the Galena limestone, above the oil-rock formation between *E* and *G*, Fig. 16. These are the true "flat-and-pitch" formations usually found below ground-water level. The flats are sheets of ore along the horizontal bedding planes of the strata and the pitches are sheets of ore located in vertical or dip-

ping crevices. Flats are shown at *M*, Fig. 16; pitches are shown at *N*, Fig. 16. Vertical cross-sections of orebodies of this type are shown in Figs. 3, 5, 6, 7 and 8, and plan views in Figs. 11, 12, 13 and 15.

Fig. 3 shows a vertical section across the Homestead and Empire mines at Platteville, Wis. This cross-section is taken on the vertical section line *CD*, shown in Fig. 15, the plan map of the same mines. The orebodies lie in a broad, flat structural basin. The Grant County and the Homestead mines are along the north side of the basin, and the Enterprise, Empire and Royal mines are along its south side. The distance from one group of orebodies to the other across the basin is about 1000 ft. The Acme mine is at the east end of the basin and shows indications of being connected with both series of orebodies, as it has both north and south pitches and has been connected with the orebodies along the north side of the basin by prospect drilling. As shown in Fig. 3, this is the type of orebody in which most of the ore and the thickest sheets of ore are found in the main or outside pitch, and the top flat is the only one that shows any great ore thickness. Differences exist in these orebodies, varying from those in which all, or nearly all, of the ore occurs in the outside pitch to those that show ore in paying quantities in the top flat and the underlying core, down to the base of the formation.

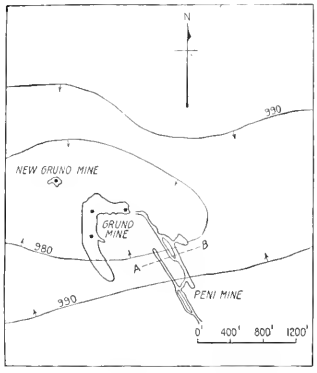


FIG. 14. MIFFLIN MINES

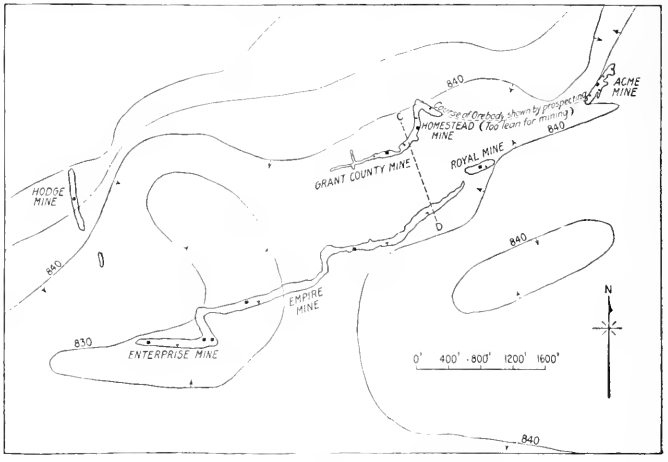

FIG. 15. MINES AT PLATTEVILLE, WIS.

Such mines as the Empire and the Enterprise at Platteville, Wis., illustrate the type where the main or outside pitch and the top flat are strongly developed, and such mines as the Klar-Piquette and the East End at Platteville illustrate the type in which the top flat and several underlying flats are strongly developed, and the outside or main pitch contains little ore, at many places showing nothing more than a crack or crevice.

Fig. 5 shows a vertical section across the Winskell mine, east of New Diggings, Wis. This section is taken on the vertical section line *GH*, Fig. 11, the plan of the same mine. This is the type of orebody located in a narrow, steep, structural basin, and mineralized in the main part of the orebody from one pitch to the other, or from one side of the structural basin to the other. In this type of "flat-and-pitch" formation, the flats and pitches seem to be about equally developed as regards the thickness of ore they carry. The Frontier mine, at Benton, Wis., and the Vinegar Hill Mine, north of Galena, Ill., are also of this type.

Fig. 6 shows a vertical section across the Federal mine at Hazel Green, Wis. This is taken on the vertical section line *JK*, Fig. 12, the plan of the same mine. This type of orebody is in a structural basin similar to the one in which the Winskell mine is located. Nearly all of the ore is in a series of pitches, and flats along the bedding planes show only to a minor extent.

Fig. 7 shows a vertical section across the Crawhall mine at New Diggings, Wis. This is taken on the vertical section line *MN*, Fig. 13. This type of orebody is in the bottom of a broad, flat structural basin. In it nearly all of the ore occurs in the flats along the bedding planes.

Fig. 8 shows a vertical section across the Hinkle mine, at Linden, Wis. This is the type of orebody with both pitches about equally developed, and flats extend from the back into the core of the mine. There is also a flat sheet of blende extending from the foot of one pitch to the foot of the other in the glass-rock formation. Orebodies of this type are in narrow depressions or channels in the structural basins. Nearly all of the orebodies near Linden are of this type, which has been used as an example of the orebodies of the district in the publications of 10 years ago.

Fig. 2 shows a vertical section across the Peni mine at Mifflin, Wis. This is taken on the vertical section line *AB*, Fig. 14. This type of orebody is usually located in the oil rock or the glass rock, and it frequently follows a series of parallel or intersecting crevices extending from the surface to the point of the location of the orebody. The ore is usually disseminated, sprangled or in the form of irregular flat sheets. The Kennedy and the Wallace mines at Highland, Wis., are orebodies of this type. The orebodies of this type frequently produce the highest-grade blende concentrates of the district, often running from 55 to 60% metallic zinc from the mill jigs.

There are numerous variations and modifications of all of these types of orebodies. New features are constantly being found in the orebodies of the district. The

chief production of the district comes from the mines in its southern half and most of these mines are of the types shown in the vertical sections in Figs. 3, 5, 6 and 7.

Prospecting Methods

Prospecting in the district may naturally be divided into drifting, shaft-sinking and churn-drilling. Previous to 1903 nearly all of the lead and zinc mines were found by shaft-sinking and drifting on crevices and outcrops. As most of the operations were conducted without power machinery, the ground-water level marked the limit to which these operations extended. During the latter part of this period the horse whim for hoisting and the horse-operated pump were the only machines used for prospecting and mining operations below ground-water level, and these were used successfully only in connection with the larger ore deposits.

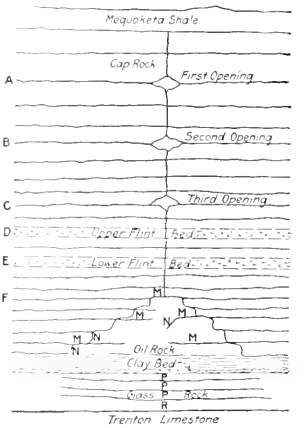

FIG. 16. VERTICAL CROSS-SECTION OF ORE-BEARING FORMATIONS

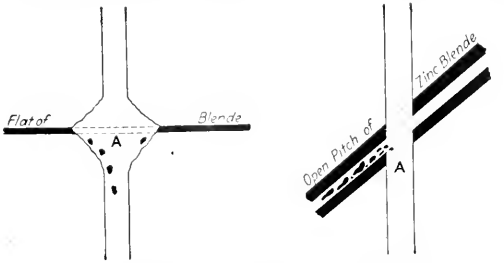
During the last 10 or 15 years most of the larger orebodies have been found by churn-drilling.

The diamond drill has been tried in the district at several places, but without success. The numerous crevices and openings have interfered with its operation. The churn drill has given the best results of any method of prospecting so far used in the district. When the ore-bearing formations are reached, the hole is sludged



FIGS. 17 AND 18. HOW ERRORS IN CHURN-DRILL SAMPLES ORIGINATE

Fig. 17—Section of drill hole showing ore dropping from flat and salting the hole. Fig. 18—Section of drill hole showing blende cuttings being lost in an open pitch.

out every 2 or 3 ft., and the sludgings that show blende to the naked eye are assayed for zinc and iron. Complete records of these holes are kept, showing the location of the drill hole, the surface elevation at its location, the nature, thickness and position of the formations passed through, and the position and the amount of the ore discovered.

Estimates based on several prospect drill holes are not always reliable, for more ore than actually exists may be shown by ore dropping from an upper to a lower level, especially when the formations are loose, thus "salting" the hole, as shown in Fig. 17. Or less ore may be shown than is actually drilled through because of its being washed into crevices or openings in the rock through which the drill hole passes, as illustrated in Fig. 18. A drill hole should never be "shot" to show the nature of the ore passed through until the hole is completed, because shooting may loosen ore and cause it to salt the sludgings at lower levels.

One of two methods is usually employed for getting the average zinc and iron contents of a drill hole. One

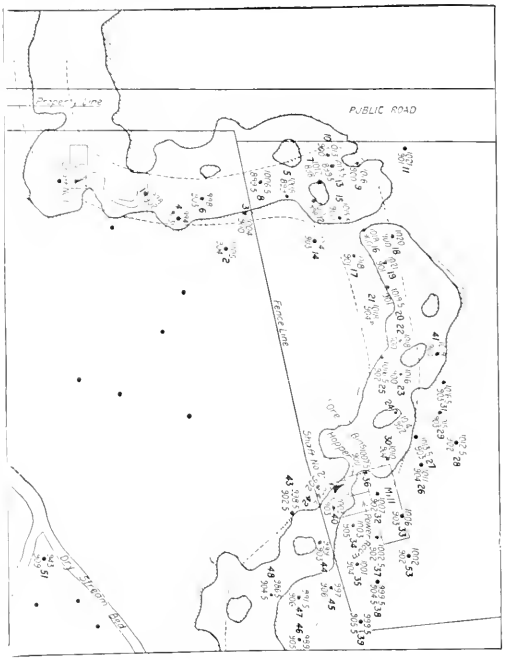


FIG. 19. A TYPICAL DEPOSIT OUTLINED BY DRILLING

method is to assay each sludging and then take a footage average of all of the sludgings from the first one containing ore to the last one containing ore, and including intervening sludgings containing no ore. The other method is to take all of the sludgings included in the former method, mix them thoroughly together and take one assay of the entire sample. The following example of a drill hole in actual practice, assayed by both methods, illustrates the plans and shows how slight errors may occur in both:

DRILL-HOLE RECORDS AND ASSAYS

Depth, Ft.	First Method Zinc Assay	Iron Assay
116-120	14.8	3.0
120-122	20.6	5.8
122-124	10.0	2.2
124-126	12.6	3.8
126-128	11.4	2.0
128-132	2.8	1.4
132-134	9.6	3.4
134-142	2.8	6.4

Total, 26 ft.; average, 8.5% zinc; 4.5% iron.

Second Method	

Total, 26 ft.; average, 7.8% zinc; 4.8% iron.

The difference in the assays in the two methods is due to the fact that equivalent footage of sludgings do not

always produce the same volumes of sludgings, because of the physical conditions existing in the strata drilled through. Each method has its advantages. Both should be used as a check for careful work.

Most of the churn-drill prospecting of the last 10 years, and the resulting discovery of zinc mines, have been at or near the old shallow lead- and zinc-carbonate workings. The old shafts and mine waste dumps have received far more consideration, up to the present time, in determining where prospecting should be done, than outcrops, crevices and geological conditions. But these old, shallow workings, not further developed by churn drill prospecting, are becoming scarce, so that the future developments will have to be made more and more in connection with a knowledge of geological and structural conditions.

After good ore is found in a prospect hole there is no great difficulty in proving up the extent of the orebody, unless it is very narrow or crooked in its course. Fig. 19 shows one of the orebodies of the district blocked out by drill holes. The broken lines represent the walls of the mine as blocked out for estimates of tonnage, based on drill-hole records, before any mining was done; and the full line shows the walls of the mine after it was worked out.

The orebodies of the district vary from 20 to 300 ft. in width, from 5 to 70 ft. in height, and from 500 to 7000 ft. in length. One of the best of the district had a length of 7000 ft., an average height of 20 ft. and an average width of 80 ft. Another had a length of 800 ft., a width of 500 ft. and a mean height of 40 ft.

(To be continued)

Canadian Nickel Production

The following data on nickel production are furnished by Consul Henry P. Starrett, of Fort William, Ont.:

It is said that the world's production of fine nickel in 1913 approximated 34,000 tons, of which the Canadian ore contained 24,838 tons; the ore produced by Le Société de Nickel in New Caledonia and refined in France contained about 8000 tons; and production in Norway amounted to 400 tons, the remainder having been refined in Germany from various metal processes. Practically all of the ore mined in Ontario was reduced to matte and shipped to the United States and Great Britain to be refined, only a small percentage having been refined in Canada.

The production of nickel in the Sudbury district—which region yields 73 per cent. of the world's output of nickel—is closely associated with that of copper, the content of the matte produced from the ore being about 50 per cent. nickel and 25 per cent. copper. The details of this production for 1911, 1912, and 1913 are:

	1911, Tons	1912, Tons	1913, Tons
Ore raised from mines	612,511	737,656	784,697
Ore smelted at mines	610,788	725,065	823,403
Bessemer matte produced	32,607	41,925	47,150
Nickel content of matte	17,049	22,421	24,838
Copper content of matte	8,966	11,116	12,938

The largest producer of this metal is the Canadian Copper Co., of Copper Cliff, Ont., its production of matte in 1913 having contained about 22,000 tons of nickel. Its output of matte was principally shipped to refiners in New Jersey. The Mond Nickel Co., of Coniston, Ont.—controlled by English interests—produced matte containing 2600 tons of fine nickel, this matte being sent to Swansea, Wales, for refining.

Under the metal refining act of 1907, extended in 1912 for a period of five years, a bounty of 6c. per lb. is paid on such metal in cobalt or nickel oxide or metal as is refined in the Province of Ontario. The only company that took advantage of this law during 1913, in respect to nickel, was the Coniagas Reduction Co., Ltd., of St. Catherines, Ont., the production of that company in the year named having been 149,645 lb. of metal.

New South Wales Mineral Production in 1914

The report of the New South Wales Department of Mines for 1914 has just been issued, and gives the figures of production shown in the accompanying table.

NEW SOUTH WALES MINERAL PRODUCTION, 1913 AND 1914

Substance	Unit	1913	1914
Alunite	tons	2,235	3,040
Antimony (metal and ore)	tons	18	36
Bismuth (metal and ore)	tons	9	15
Coal	tons	10,414,165	10,390,622
Coke	tons	298,612	304,800
Copper (ingots, matte and ore)	tons	9,461	6,607
Diamonds	carats	5,573	1,580
Gold	oz.	149,657	124,507
Iron	tons	46,563	75,150
Iron, "oxide"	tons	3,204	3,144
Lead (pig, etc.)	tons	23,554	25,989
Lime	tons	33,272	36,207
Limestone flux	tons	42,663	51,852
Molybdenite	tons	79	61
Platinum	oz.	442	244
Silver (ingots and matte)	oz.	2,194,871	2,871,559
Silver-lead, ore, concentrates, etc.	tons	391,262	337,019
Shale (oil)	tons	16,985	50,049
Scheelite	tons	44	57
Tin (ingots and ore)	tons	3,021	2,317
Wolfram	tons	126	130
Zinc (spelter and concentrates)	tons	506,661	359,319

In addition to the foregoing, marble valued at £2180, opal, £26,534; portland cement, £415,000; building stone, £401, and sundry minerals and ores valued at £5512 were produced in 1914.

The total value of the mineral yield in 1914 was £10,499,720, a decrease of £1,595,364 from that of the previous year. However, considering the disabilities under which the mining industry has labored since the outbreak of war in August, 1914, the production must be regarded as very satisfactory. It has only been exceeded on three occasions, namely, in 1907, 1912 and 1913.

The number of persons employed in mining in 1914 is estimated at 37,470, a decrease of 1410 from figures of the previous year.

Arizona Copper Co.

The Arizona Copper Co., Ltd., Clifton, Ariz., reports for the half year ended Mar. 31, 1915, a profit of £187,899, before payment of debenture interest and dividends, and a balance before payment of dividend on the ordinary shares of £137,303, from which a common dividend of £75,995 was paid.

The production of copper for the half year was 8774 tons, against 9469 tons for the corresponding period of last year and 9909 tons for the half year ended Sept. 30, 1914. The question of the recovery of copper from tailings by means of oil flotation is still under consideration. Agreements have been entered into which will enable the company to introduce oil flotation when experiments that are being carried through at Clifton have demonstrated which particular process is best adapted for treating the company's ores.

The Sampling of Churn-Drill Prospect Holes

By Frederick G. Moses*

SYNOPSIS—Bailing difficulties with dart-valve bailers and results of foreign rock getting into sludge discussed. Splitter designed for cutting down sludge samples automatically. Points to be watched in drying samples and taking and drying a geological sample.

The value of churn drilling, as a means of prospecting for orebodies, depends on the care with which the sampling is done. Of course, in order to get accurate samples in any kind of sampling operations, care and cleanliness are imperative, but this is more especially true in the sampling of churn-drill holes. Many factors enter into this work that make it even more difficult than a superficial glance at the subject would lead one to suppose.

The process of sampling a churn-drill hole, as viewed from a practical standpoint, consists essentially of three operations: (1) The actual bailing of the sludge from the hole, (2) the cutting down of the sludge to the amount required for a sample, and (3) the drying and sacking of the samples.

Bailing

Common practice in the West is to take a sample interval of 5 ft., but this distance may be more or less, depending on the physical character of the formation and the value of the orebody being drilled.

Probably the most fruitful source of unreliable samples and at the same time the hardest operation to carry on in a way to give good results, is bailing.

The two most important factors encountered in bailing which tend to cause poor sampling results are: (1) The drillers can only be made, with the greatest difficulty, to run the bailer enough to clean the hole thoroughly each time, and (2) the mechanical construction of the bailer that is most often used is such that it is impossible to bail the hole absolutely dry.

The bailing operation is a fairly slow one, and when the hole is deep, a great deal of time is taken up in bailing. The drillers are anxious to make good progress and, as a result, hate to spend any more time in bailing than is absolutely necessary to clean the hole enough so that the sludge left in it will not interfere with the drilling. The result is that they leave 10% or more of the sludge in the hole. Of course, this sludge that remains goes into the next sample and if there is any difference in the ore content of the two intervals, it will salt up or down, as the case may be, the sample from the lower interval. The only remedy for this fault is careful supervision of the bailing by some one with the power to enforce careful work.

The second important factor is the mechanical construction of the bailer commonly called the "dart-valve" type, Fig. 1. The bailer is so built that the valve in the bottom of the instrument is opened by the weight of the bailer resting on a lug that projects through the valve opening. When the bailer is lifted the weight of the valve and the sludge above will close the valve. When the bailer is on the bottom of the hole and the lug has opened the valve, the bottom of the bailer proper is still 6 in. from the bottom of the hole. No matter how many times the bailer is run, it is evidently impossible to get the amount of sludge equal to the length of this lug into the bailer. This amount of sludge is so small, however, that unless there is a great difference between the assays of the two adjacent samples, it will not cause an appreciable difference in the assay of the following sample.

A partial remedy for this fault of bailing is a system of progressive dilution that is sometimes used in particular work, or in holes that are in high-grade ore. After all of the sludge that can possibly be taken out with the dart-valve bailer is extracted, two or three bucketfuls of water are thrown into the hole. The bailer is then run into the hole and worked up and down in order to mix the newly added water and the sludge that had been left in the hole by the bailer. The bailer is now pulled from the hole and emptied. Of course, the total amount of material, sludge plus water, is the same as the previous amount

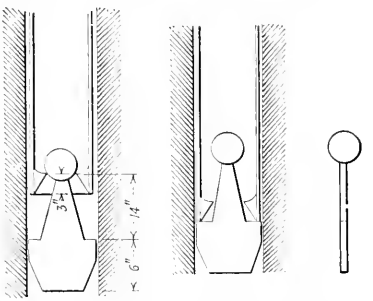

FIG. 1. TYPE OF DART-VALVE BAILER

of sludge, but the total amount of solid matter is less because of the dilution caused by the water that was added to it.

Besides these two difficulties in bailing that have been mentioned, there are several of lesser importance that should also be noticed.

Knocking Foreign Material into the Sludge

One of the greatest of these lesser evils is the dropping of material from the walls of a hole that is caving slightly. A churn-drill hole is very likely to cave, especially the part in a brittle sulphide ore, without being noticed, unless it is watched closely and carefully. Casing a hole is a laborious and often difficult operation, and if the caving is not great enough in extent to interfere with the drilling operations, the driller is likely to say nothing about it. As long as this state of affairs exists the cavings will drop to the bottom of the hole and become mixed with the sludge that is to form the sample from the interval that is being drilled. The result is a sample that is bound to be salted one way or the other, depending on the character of the caved material.

*Churn-drill sampling department, Detroit Copper Mining Co., Morenci, Ariz.

There is also another way in which material can be knocked into the hole, and that is by the drilling tools, when they are being lowered into the hole, after the bailing has been completed and drilling is to be resumed. The string of tools to which the bit is attached is from 30 to 40 ft. or more in length. As this mass of metal is rapidly lowered (as it always is) into the hole, it will vibrate back and forth and, on striking the walls of the hole, knock off pieces of the wall rock. This will continue all of the distance down the hole and, when all of this loosened material has collected on the bottom, will frequently be great enough in amount to cause a noticeable difference in the sample to which it will be added.

Sludges Which Pack

Some sludges, because of a lack of light kaolinized material, will pack in the bottom of a hole as soon as the tools are pulled out of the hole. When material of this sort is being dealt with, the bailing should be done as quickly as possible, and each time the bailer is run down it should be pulled up a small distance and then dropped down again. This is done in order to keep the cuttings mixed as well as possible between the bailer trips.

In extreme cases only, where the sludge is so heavy that it cannot be agitated enough to get it into the bailer, a little clean clay may be added to the hole. This material will mix up with the heavy cuttings and cause them to float, more or less, so the bailer can pick them up. When foreign substance has been added to a sample it must be marked "unreliable" even though the amount added is so small as to make no noticeable difference in the assay results.

Cases have been cited where the driller could not get this sort of sludge into the bailer after the first or second trip. Instead of trying to mix the cuttings and the slimes together and then bail, adding something to make them mix, he would stop running the bailer and commence to drill. This procedure would cause the sludge left in the hole to become mixed with the sludge from the next, and make each sample overlap the next. Conditions like this give an assay result that is worthless, because it is an average of the two adjoining intervals instead of an accurate value of either.

Cutting Down the Sample

The second operation of sampling, that of cutting down the sludge to the amount required for the sample, offers no difficult or unusual problems, but nevertheless, it will always bear the closest supervision.

The amount of sludge obtained from a churn-drill hole in an interval of 5 ft. depends largely on the size of the hole and the amount of water that is necessary for the drilling of the interval. The amount of sludge may vary from, say, three to 10 tubfuls, or even more. This large amount of material must be cut down to a quantity that may be dried and sent to the assay office, and at the same time represent the exact chemical composition of the total amount of sludge taken from the sample interval.

There are two common methods of reducing the total bailing to a convenient sample size. Cutting down the sludge is carried on in order to get this pail of material that will accurately represent the whole amount of material bailed. The first way of cutting down is by hand, and the second method, and probably the best, is by the use of an automatic splitter. The second method has many points in its favor and should be used.

The hand method of cutting down the sludge is simple, and care on the part of the sampler is all that is required to get an accurate sample. The procedure is about as follows: The sludge is dumped from the bailer into a launder of heavy construction, see Fig. 2. At the end of this launder is a Jones sampler—so common in assaying and sampling establishments. This sampler is so placed that all of the sludge that is thrown into the launder will go through it. A tub is then placed under the divider in such a way as to catch half of the sludge, while the other half is allowed to run away as discard. As soon as one tub is filled in this manner it is replaced by another until the bailing has been completed. When this has been done the launder is flushed out with a pail of clean water, in order that the heavy material in the sludge may be washed into the sample. The tubs of sludge are then poured back through the divider as often as required to get the

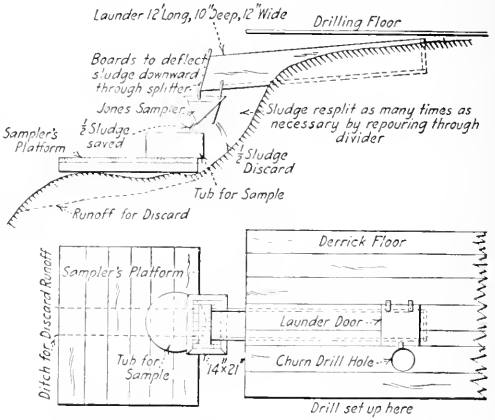

FIG. 2. ARRANGEMENT FOR HAND SAMPLING

sample to the size desired. To accomplish this usually takes five or six more reductions. The sample is now ready for drying.

During the above operation there are several points to be watched. The first is to see that the sludge comes onto the divider as near the center of it as possible. This is to get the most accurate division of the bailing.

The second point is to see that none of the sludge splashes over the sides or ends of the divider and into the tub. It is imperative that all of the material should go through the divider. A remedy for a fault of this kind is to nail a few boards on the end of the launder in such a way that when the sludge strikes these boards it will be deflected downward into the splitter. Usually the rush will be so great when the bailer is dumped that it will be necessary to caulk the cracks between the boards with cloth to keep the material from going between them.

Churn-drill sludge, especially when the hole is traversing a kaolinized or clayey zone, is very heavy and it may be semiliquid. When a sludge of this type carries sulphides they will tend to float. When this material is being resplit, the sampler must use great care in pouring it through the divider or a part of these floating sulphides will flow over the side of the divider and be lost to the sample. These sulphides, in most cases, run the highest in metallic values and to get an accurate assay of the sludge, none of them must be lost.

Often the hole is [illegible] two during the drilling of one sample interval. When this happens, the tubs that are first filled have to stand for a time before the sample can be cut down. With nearly all types of sludge, especially the thick clayey kind before mentioned, difficulties are experienced with the heavy particles and much of the clay by settling to the bottom and sides of the tub where they stick tight. When this happens the sampler must be careful to wash the tubs out over the splitter with a hose, to get this material, which often carries high values.

With the automatic splitter, the sludge is split four or five times, instead of once, before it is caught in the pans or tubs, which means the saving of a great deal of time and also the eliminating to a large extent of the human factor. In sampling this is of great importance. Instead of the sampler having five or six chances to be careless, he can be careless only two or three times. With a small amount of bailed material it will not be necessary to resplit at all, and in the case of a large amount it may have to be cut once or twice more after coming through the automatic divider.

A type of automatic splitter, Fig. 3, that has given satisfactory service for the Detroit Copper Mining Co., at Morenci, Ariz., consists of two 12-in. boards 12 ft. long, placed side by side on end and 2 ft. apart. At regular intervals, between these boards are placed four Jones samplers. The first two of the samplers are 14x21 in. The one next lower down is 11x13 in., and the bottom one is 9x11 in. These samplers are placed one above the other and connected by sloping troughs about 2 ft. long. The splitters are so arranged that the sludge runs out of the launder into the first of the dividers which splits it, throwing half of the sludge, the discard, to the ground and the other half of it into the trough. The half that is to be saved then runs down this trough and into the next lower divider. This operation is repeated by each of the splitters in turn until the product from the last of them is only $\frac{1}{16}$ of the total amount of material bailed. The object of the troughs between the dividers is simply to mix the sludge after it has been cut. As mentioned above, with a medium amount of sludge the sample will need no more cutting, and when large amounts are bailed it will be necessary to resplit it by hand only once or twice, as the case may be.

This divider was designed by G. F. Carr, of the Detroit Copper Mining Co.

The only point to be watched when using this apparatus is to see that it is washed thoroughly with a hose each time after it has been used, in order to get any heavy or sticky material out of the way of the next sample. When it is necessary to resplit the sample once or twice more by hand, the same precautions must be observed as when the whole operation is done by that means.

Drying and Sacking

After the sample has been bailed and cut down, the only operation that remains is the drying and sacking. This work is of the simplest nature, and with a little care should give no trouble. However, there are a few things that must be noticed.

When a hole is deeper than, say, 400 ft., the sludge will often contain gases dissolved in it. These gases are principally CO_2 and H_2S. During the process of drying a sample of this kind, these gases will be expelled. As the gases are driven from the solution by the heat, they will cause foaming to a greater or less extent, and at the same time carry some of the finer of the sulphides to the surface of the liquid with them. If the pan in which the sample is being dried is too full, some of this foam may bubble over the side of it, and cause the loss of some of the fine sulphides, which will cause a low assay. There are two remedies for a sample that acts in this manner: use a pan that is large enough so that the danger of boiling over will be avoided, and dry it over a slow fire.

There is one point that must be watched when sacking any kind of a fire-dried sample. In the drying process the agitation due to boiling will naturally carry the heavier pieces in the sample to the bottom. The foam mentioned before will also be dried on the surface of the cake and a good deal of it will stick around the edges of the pan just at the top of this cake. Great care must be used when sacking a sample to which these two things have happened to see that the pan is scraped thoroughly, both

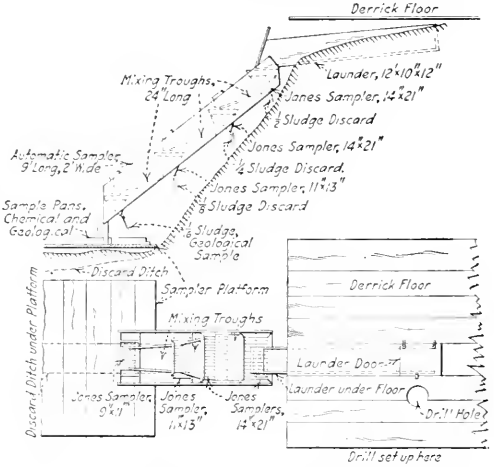

FIG. 3. ARRANGEMENT FOR AUTOMATIC SAMPLING

sides and bottom, to loosen all of this material and get it into the sample. This material will carry the high-grade, if any, which makes it doubly important.

Taking Geological Sample

The above considerations have dealt with samples for chemical analysis only. The large companies that are doing extensive drill prospecting often want a geological sample from the same intervals from which the assay samples are obtained, so that they can, besides learning the value of the ground being drilled, get some idea as to the rock formations in which their ore is being found. When these geological samples are taken they are obtained from the same material as the chemistry samples.

A geological sample is simply a portion of the sludge from which all of the clay and mud has been washed. A convenient way to take this sample is to save and wash the discard from the last splitting of the assay sample. This material is then dried, labeled, sacked and sent to the geologist.

The washing of the geological sample must be [illegible] done. The principle used in treating these [illegible] to get rid of all of the material that will interfere with the mineralogical determination that is made later, and at the same time to have as small a loss of the minerals in

the sample as possible. Special care must be used when washing a sample that is high in kaolinized material, for this, when dry, will make a great deal of dust, causing a dirty sample.

The sludge to be used for the geological sample is diluted until the required amount of cuttings has been thrown down. Everything except these rock cuttings is then carefully poured over the end of the pan and the cuttings that remain are washed as many times as necessary to clean them well.

The sample is next dried. It is best to do this out of direct contact with the fire for the reason that if it is put directly on the fire there is the possibility of its getting so hot that the sulphides present may be roasted to the oxides, and other minerals present be broken up into their component compounds. If this does happen, the value of the sample as an index to the formations that are being penetrated is lost.

The necessity for a careful, intelligent and responsible churn-drill sampling force cannot be emphasized too much. The reliability of the results obtained from the drilling on the property depends directly on this force, and the money that may be saved by a poor, cheap or inefficient sampling organization is earned in the most expensive of ways.

Shannon Copper Co. in 1914

The report of the Shannon Copper Co., Metcalf, Ariz., for 1914 shows a net profit of $95,649 from a production of 9,003,169 lb. of copper, 1295 oz. of gold and 69,603 oz. of silver. The average price received for copper was 13.626c. and for silver 55.78c. Proceeds from all metals amounted to $1,291,539. Operating expenses were $992,527, and freight, refining and eastern expenses, $127,841. Development, interest and taxes amounted to $69,974, and other income, $21,525. There was also a charge of $23,739 for expenses while not operating during the fourth quarter of the year, and $3331 for a net loss on the operation of the Shannon-Arizona Railroad Co.

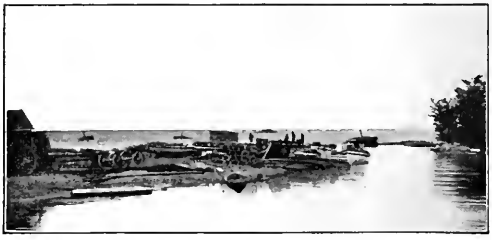
During the nine months of operations the smelter treated 154,300 tons of ore from the Shannon property and 38,997 tons from outside claims. The average copper extraction from the ores of the Shannon mine was 52.76 lb. per ton and 16.68 lb. per ton from the outside properties. The average cost of copper sold in New York was 12.26c. per lb. Net current assets in excess of current liabilities amounted to $349,388, exclusive of $383,000 of Shannon-Arizona railway bonds which the company holds in its treasury. There are now only $198,000 of these bonds in the hands of the public out of an original issue of $600,000. During the year 4462 ft. of drifts and crosscuts were run at a cost of $25,659, about $5.75 per ft. Operations were resumed in full Mar. 1, 1915.

Big Timber Cut in Alaska

A permit to cut 85 million feet of timber in the Chugaeh National Forest for use in constructing the new government railroad from Seward to Fairbanks has been received from the Forest Service. The cutting is to be done so that only mature trees are taken; the young trees being left uninjured and the condition of the forest thus improved. This cut of 85 million feet will be the largest amount of timber ever felled on the Alaskan forests in one operation, and at the average rate per thousand board feet obtained for timber sold from the Chugaeh Forest during the fiscal year 1914, it is worth approximately $145,000 on the stump. It will be nearly twice as much as the total quantity of national forest timber now cut and used annually for local purposes throughout Alaska, but only a little more than one-tenth of the estimated annual growth of the Alaskan forests. The two national forests of Alaska contain about 78 billion feet of merchantable timber, and it is estimated by the Forest Service that more than 800 million feet could be cut every year without lessening the forests' productivity.

Difficult Transportation at the White Pine Mine

The accompanying illustration shows the difficulties which the White Pine mine in Michigan has in getting its output to the smeltery at Hubbell from the mine. The White Pine is a newly developed subsidiary of the Calumet & Hecla, situated 16 mi. from Ontonagon, and is still without rail connection. The copper rock is mined



TRANSPORTATION AT WHITE PINE MINE

and milled at the mine, then hauled in barrels over a rough corduroy road to the point shown in the illustration, then hauled in scows from the mouth of Iron River into Lake Superior and thence to the smelting plant by tug. The tug shown in the background cannot come nearer shore, and the scow loaded with copper has to be towed out to it by a powerful gasoline boat.

Antimony Smelting in the United States

The Chapman Smelting Co. of San Francisco, which smelted antimony a number of years ago, has resumed operations, and in addition a new antimony smeltery has been erected near San Pedro, which is reported as working upon ores from Wild Rose Cañon near Ballarat, Calif. Antimony ores have been sold and shipped from Alaska, California and Nevada, according to the United States Geological Survey.

The *Journal* is advised that the San Pedro smeltery is operated by the Western Metals Co., of which M. Elsasser is president, with offices at 625 Security Bldg., Los Angeles, Calif., and that the Merchants Finance Co., of San Francisco, is erecting a plant at Harbor Industrial City, Calif., of 1000 tons per month capacity, to cost about $75,000.

Metal Loss in Copper Slags—III

By Frank E. Lathe*

SYNOPSIS—*A general consideration of the data presented in the preceding articles and the suggestion that slag losses can be reduced in many instances by careful study of conditions. Serious loss from dissolved cuprous sulphide not considered proved. Loss from suspended matte particles may be reduced by better settling facilities. From one-half to three-quarters of the copper lost in slag is in the oxidized form; various remedies have been suggested by different operators.*

The constitution of mattes and slags is not well enough understood to enable us to formulate definite rules governing their mutual behavior. Recent experiments by Professor Guess and myself at the University of Toronto have shown that artificial mixed sulphides of copper and iron vary greatly in both composition and properties, according to the conditions under which they have been prepared, and that it is not easy, if at all possible, to duplicate in the laboratory the mattes produced in commercial smelting. This fact probably accounts in large measure for the contradictory results obtained by different investigators of the problem.

Complexity of Matte Composition

The main constituents of ordinary mattes are Cu_2S and FeS, mutually soluble in all proportions in the molten condition. They form a eutectic containing about 25% Cu, but the existence of compounds is still a debatable question. If they do exist they seem to have no striking effect upon the general properties of matte. Metallic copper may be seen in many specimens of matte, but is soluble in molten Cu_2S, separating only on solidification. Metallic iron, usually present, varies greatly in quantity, being produced chiefly under the conditions nearest those of the iron blast furnace—high temperature and strong reducing action—the usual requirements for the production of highly siliceous slags in copper blast-furnace operation. It may, however, be mainly due to a dissociation of FeS, in the excess of which it dissolves readily. When zinc, lead, arsenic and antimony are present in the furnace charge they are usually found, in part at least, in the matte; ZnS and BaS in the matte lower its specific gravity. Silver is likely to be in the form of Ag_2S, very soluble in Cu_2S, less so in PbS, and but slightly in FeS, Fe, and ZnS. Gold, chemically very inactive, is probably present as metal, readily soluble in Cu_2S, Cu and Fe, less so in the other constituents. With the exception of Fe_3O_4, which may be present in quantities up to 10% or higher, oxides are practically absent from mattes. The metallography of mattes has been discussed at length by Professor Fulton[3].

The identification of compounds in slags, as carried out by Vogt, is of less value to this discussion than a consideration of the effect of various acids and bases on fluidity and specific gravity, two factors of prime importance, and on the observed copper content. In this connection Waujukoff's curves[4], Figs. 3 to 6, are of interest. In his experiments an increase in the SiO_2 was attended by favorable results, also a replacement of FeO by CaO, Al_2O_3, or MgO, while ZnO in more than small amounts was decidedly detrimental. Both Al_2O_3 and MgO replaced CaO to advantage.

Of these indications the effect of an increase in SiO_2 within reasonable limits is fully borne out in practice, and the data available seem sufficient for a general conclusion. The same is true, though perhaps to a less extent, of the replacement of FeO by CaO. Of course the extent of this replacement is limited by the fluidity of the slag, which almost requires the presence of FeO or its equivalent, MnO, in some quantity. For the same reason the Al_2O_3 or MgO should be kept within bounds, although practical slags show that fair amounts of these oxides do not always increase the viscosity of the slag to such a point that good settling is difficult. ZnO has a particularly bad effect, increasing both the viscosity and the specific gravity of the slag.

Referring to Professor Hofman's list of blast-furnace slags[5]—Table 1—it will be seen that in general the clean slags are high in SiO_2 and CaO, and sometimes Al_2O_3, being thus of low specific gravity, and have been produced with a matte low in copper. At the other end of the list these conditions are generally reversed, although in some cases the reasons for high slag losses are not apparent. The combined effect of low SiO_2, CaO and Al_2O_3, and high ZnO, producing a heavy slag and light matte, is well illustrated in No. 26. BaO does not appear to be detrimental, in spite of its high specific gravity, as two slags, Nos. 6 and 18, containing it in largest proportion are cleaner than one would expect from the other conditions. More light would probably be thrown upon some irregularities if the viscosity of each slag were known. The losses in reverberatory smelting[6]—Table 2—are more uniform than those in blast-furnace practice, and somewhat higher, due to the more nearly uniform composition and high percentage of FeO.

Loss of Copper as Suspended Matte Particles

Considering now an intimate mixture of matte and slag in the molten condition, copper may be lost in several different ways. Suspended matte particles will be first considered. That these particles are usually present, in small amount at least, few metallurgists will probably deny. They may be seen on careful examination in some slags which have no more than 0.20% total copper. If not due to the separation of dissolved sulphides on solidification of the slag, this matte is lost through imperfect settling which may be caused by insufficient difference between the specific gravities of the matte and slag, to the viscosity of the slag or to the very small size of the matte globules. The influence of all these factors is well shown by Sir G. G. Stokes' formula for the law of viscous resistance:

$$v = \frac{2}{9}\frac{g}{\mu}\left(d - d^1\right) r^2$$

*Chief chemist, Granby Consolidated Mining, Smelting & Power Co., Ltd., Grand Forks, B. C., Can.

[3]"Principles of Metallurgy," Chapter IX.

[4]"Engineering and Mining Journal," Aug. 7, 1915.

[5]Ibid.

[6]Ibid.

where v is the terminal velocity of settling particle (sphere), g the acceleration due to gravity, d the density of sphere, d' the density of fluid, n the coefficient of viscosity, and r the radius of sphere. Thus an increase of $d - d'$ may be accompanied by a corresponding reduction in the time of settling, as may also any decrease in viscosity. To illustrate the great effect of variation in r—if a particle of matte of 0.1 in. diam. requires 10 sec. in which to settle, then one of 0.01 in. diam. would require 16⅔ min. Viscosity is perhaps not usually a serious factor, though it is liable to become so with high ZnO or Al_2O_3, or with high SiO_2. Slags of such composition require to be heated considerably above their formation temperature to give sufficient fluidity, while the irony slags, though perhaps formed only at higher temperatures, become very fluid when but slightly superheated. Thus the formation temperature is not nearly as important as might be supposed, the temperature at which the slag will be sufficiently fluid to allow the matte particles to settle within a reasonable time being the minimum permissible.

These losses as suspended matte particles may be reduced by securing greater fluidity in the slag—whether by changing its temperature or composition—by making a slag of lower specific gravity, or by coagulation of the matte particles. As some of these factors work against each other—FeO often increasing both fluidity and specific gravity—it is essential that no condition be changed without its total effect being noted. A compromise will usually be necessary to secure the best results.

Copper Settler Practice

Most metallurgists believe, if one may judge by the common practice, that one large settler, about 15 ft. in diameter, will allow to settle all the matte particles which can be economically separated from the slag. However, this question appears to be worth further investigation. At the Granby's Grand Forks smeltery a large settler was substituted for two small ones, as an experiment, and as long as it was in operation the slag passing through it carried more than the normal amount of copper. The reasons for it are not quite clear, but it is often noticed in analytical chemistry that thorough stirring is followed by a coagulation of precipitates, and the cascading of the slag from one settler to another with a drop of some inches may have a similar effect upon the suspended matte particles. It is certainly unwise to allow a slag to pass to waste without first determining by trial that the amount of copper which might be recovered in a second settler would not pay for the additional expense. To give again the experience of the Granby, up to seven settlers in series have been tried, and some matte has been recovered even in the last of these, while not less than three give the best commercial result. In any particular case the degree to which the slag has been superheated in the furnace will largely determine the length of time during which it may subsequently be economically treated. As already noted, the average temperature of the matte and slag issuing from the Granby furnaces is about 1275° C., though the slag will flow at 1100° C., and its formation temperature may be considerably lower.

If a slag contains a certain percentage volume of suspended matte it is evident that the amount of copper thus lost will vary directly with the grade of matte. While low-grade matte involves additional expense in a subsequent operation, the cost of treating it has materially decreased since the introduction of pyritic smelting and basic converting. It must be remembered also that in its production the amount and specific gravity of the slag decrease and its composition changes, becoming more siliceous, while the specific gravity of the matte also decreases. The first three factors tend to decrease the copper in the slag, and in practice far outweigh the tendency of the last to increase it.

In the curves—Figs. 1, 2 and 8[7]—given to show the result of actual operation at different smelteries, there is a flattening between about 32 and 38% matte. In other words, a variation in the grade of the matte between these limits had no considerable effect on the copper content of the slag. Both above and below these percentages the change in the slag was more marked. This points to 37-38% matte as a desirable grade to produce unless it can be reduced below 32%. No satisfactory reason has been suggested to account for this.

From the small amount of information at hand it may be stated that in some cases at least the loss of copper as suspended matte is not more than 25-50% of the total loss in slag.

Loss by Dissolved Cuprous Sulphide Not Yet Proved

The phrase "solubility of matte" has unfortunately been loosely used by some writers, who often mean by it, in the subject they have under discussion, the total amount of copper retained by the slag, whatever its condition. In this paper it is used in its ordinary chemical sense. The amount of Cu_2S dissolved is a constant under any given set of conditions, but varies with the composition and temperature of the slag, and is probably thrown out of solution when the slag solidifies. It seems altogether likely that such a solubility does exist, though perhaps small, as we learn from chemistry that most "insoluble" substances possess a definite and measurable solubility. That the matte particles found in slag are not due to the separation of dissolved matte, on solidification, seems probable from their appreciable size. If chemical compounds exist in the matte we may expect them to dissolve as such in the slag, while if they do not exist, the various constituents of the matte will have separate solubilities, in the slag and in one another.

It is difficult to conceive of any direct method of determining the actual amount of Cu_2S thus dissolved in any slag, especially if it separates on solidification of the latter. The best we can do perhaps is to estimate it by difference. First, we can calculate the amount of suspended matte from the gold-copper ratios of matte and slag. Then we may determine the amount of copper in the oxidized condition. The difference between the sum of these and the total copper in the slag might be accepted as dissolved Cu_2S, but, as already seen in Mr. Kiddie's experience and at Grand Forks, the only places from which such data are available, there is no appreciable difference of this kind. While the evidence is not such as to enable me to state a general rule I may at least say that the existence of dissolved Cu_2S in slag in determinable quantities has not yet been proved.

It is indeed fortunate that such appears to be the case, for the difficulty of reducing such a loss would be considerable. A possible corrective measure would be

[7] "Engineering and Mining Journal" Aug. 7-14, 1915.

to reduce its solubility in the slag by changing conditions. Of these the temperature—with which solubility might be expected to increase—is already as low as is consistent with thorough settling. A hopeful change would be in the composition of the slag. If the dissolved Cu_2S is dissociated (Hofman states[8] that it is a good conductor of electricity), the addition of pyrite and consequent increase in the number of sulphur ions would tend to precipitate the copper.

Losses of Copper in Oxidized Form

Oxidized copper may be present in slags as cuprous or cupric oxide or as silicate. As the opinion has been freely expressed that none of these really exists in considerable amount in ordinary slags, it may be well to review the evidence. (1) The amount of copper dissolved from some normal slags at moderate temperatures by either dilute HCl or H_2SO_4 is much greater than that dissolved from mattes. If all the copper were present in the same condition in both instances one would expect the opposite to be the case. (2) The copper oxidized, as determined in this way, appears to check the estimated amount too closely to be the result of accident. (3) When copper oxide and silicate are actually introduced into a slag, even though they be intimately mixed with matte, and the whole is fused, the amount of copper remaining in the slag is considerably more than the normal. This shows that the reaction between sulphide and oxide is not complete under such conditions. (4) When a slag is given the treatment necessary to reduce the copper oxide, if it be present, the copper content of the slag is materially reduced. From the foregoing it seems reasonable to conclude, not only that oxidized copper does exist in normal slags, but that its amount may be at least approximately determined.

It does not appear to be of great consequence whether the copper be in the slag as oxide or silicate, the method of reducing it would probably be the same in either case. One would think, however, that no oxide with a considerable affinity for SiO_2 would long remain uncombined, at least in a siliceous slag. Cu_2O, if present as such, would probably color the slag red, while CuO is unstable at the ordinary furnace temperatures.[9] But what is of real importance is the fact, if we may call the conclusion such, that in all the normal furnace slags tested, though they were made under radically different conditions, from a half to three-quarters of the copper lost existed in the slag as oxide or silicate, and not as sulphide.

This being true, particular attention should be directed to possible means of reducing the loss. Mr. Wright—in the article already reviewed—told of passing slag made in two reverberatory furnaces into a third, this one containing matte of low gold and silver content. While he did this only to save the precious metals otherwise lost in the slag from the first two furnaces, it is evident that the treatment might be applied to the reduction of oxidized copper as well. Mr. Kiddie made the definite suggestion of passing a slag containing copper oxide over a bath of low-grade matte in a second settler. The difficulty appears to be to introduce this matte and keep it in the molten condition for a long period of time. If it were produced directly from pyrite in the settler some additional heat would probably have to be provided. Mr. James, in speaking of converter slag, favored the plan of an externally fired settler into which pyrite was dropped to reduce the copper oxide. The most hopeful suggestion, however, was made by E. J. Carlyle. He thought if a wall of refractory material were built across a reverberatory furnace near the skimming end, high enough to keep back the main body of matte, but low enough to allow the slag to flow over it, that pyrite could be charged through the roof between this wall and the skimming door, with a material reduction in the copper content of the slag. A separate tap-hole could be provided for the low-grade matte as well as a side door behind the dam for the removal of floaters. Such a practice would not involve radical changes in construction, and would appear to be of general application in reverberatory smelting. At any rate the experiment is well worth trying, particularly as the loss as oxide in reverberatories is probably much greater than in blast furnaces.

The Cleaning of Converter Slag

This question of oxidized copper is of considerable importance in the treatment of converter slags, at least in those smelteries so situated as not to require it in their blast furnaces. While the custom of pouring molten converter slag into blast-furnace settlers may be commercially, even if not metallurgically, the best practice in some instances, such a course should certainly be adopted only after a thorough investigation of the copper content of the overflowing slag before, during and after the pour. Some sulphide would be settled and some oxidized copper would be reduced by the matte, but the dilution by blast-furnace slag would ordinarily be such as to render the losses actually taking place difficult to determine accurately. Results of the Anaconda company's proposed treatment of converter slag in a special reverberatory furnace will be awaited with interest. .

The similar behavior of the sulphide and oxide (or silicate) of copper under remedial treatment is worthy of note. Thus in the settling experiments not only was the sulphide settled, in part at least, but the oxidized copper in the slag decreased also. This is probably due to the fact that oxidizing agencies (blast and Fe_3O_4) were no longer at work, and the oxidized copper was reduced to its normal amount. Also in the treatment of slag with low-grade matte not only was its particular purpose accomplished, but sulphide also settled. In the case of adding pyrite to a slag to reduce the oxide it would probably carry down with it some of the suspended sulphide, much as the shower of lead in an assay crucible acts as a good collector of the precious metals. It is fortunate that this suggested treatment for slag promises well for a saving of the copper, in whatever form that may be held.

While gold and silver losses may often be considerable, they have not been dealt with at length for the reason that they are not so readily adapted to experimental work and because any method which proves successful in settling a considerable portion of the suspended sulphides in a slag may be expected to reduce these losses also. Suspended matte probably carries its normal proportion of the precious metals, but their actual solubility in slag is small, if not negligible. Silver is oxidized less readily than copper, and gold little if at all. Thus comparing the copper, silver and gold content of slags and their accompanying mattes one would expect silver to occupy an intermediate position. Mr. Wright and Mr. Heberlein found this to be the case in the instances referred to. As mentioned before,

[8] "Metallurgy of Copper," p. 54.
[9] Ibid, p. 13.

silver has not been regularly determined in Granby slags, so that no accurate averages are available, but the assays performed easily place silver between copper and gold in this regard.

In conclusion, it may be said that the question of slag losses, like most others, must be solved separately for each set of conditions. It is my belief, however, that many smelting companies may yet do something to improve their practice in this particular.

Katanga Increasing Its Output

At the annual meeting of Tanganyika Concessions, Ltd., in London on July 23, 1915, Robert Williams presented some interesting data with respect to the progress of the Union Minière du Haut Katanga, the principal mineral interest of the Tanganyika company. The latter showed a debit in its profit-and-loss account of £136,825 owing to the fact that up to the present no income had been received from the Union Minière du Haut Katanga. Following naturally upon the postponement of interest on the first debentures, the payment of interest (£42,250) due on the second-mortgage debentures has likewise been postponed until six months after the conclusion of the war. Mr. Williams, in reviewing the work at Katanga, said:

Active mining work has during the past two years been carried on at Kambove, Luushia and the Star of the Congo mines, and on the Musoshi iron deposits for ironstone flux. The total ore and flux mined in 1914 amounted to 360,000 metric tons, which was more than double the quantity (170,000 metric tons) mined during the previous year.

The cost of ore on trucks at the mines is being gradually reduced. The costs at present average as follows:

Kambove .....about 4s. 5d. ($1.07) per metric ton
Star .....about 6s. 10d. ($1.66) per metric ton
Luushia .....about 7s. 8d. ($1.86) per metric ton

The improvement in mining costs will continue as the exploitation progresses and the low-grade treatment schemes come into operation, and it is estimated that the high-grade ore at Kambove should not cost more than 2s. to 2s. 6d. (48 to 60c.) per ton and the low-grade ore about 1s. 3d. (30c.) per ton on trucks at the mine by the end of 1917.

ESTIMATE OF ORE RESERVES

The ore reserves and stocks already opened up above the present working levels at Kambove, Luushia and the Star mines, as estimated for the end of 1914, amount to a total of 6,026,500 metric tons, while the approximate flux reserve estimated for the Star and Musoshi amounts to about 900,000 metric tons. Of the ore reserves estimated above, about 20% of the total is direct-smelting ore of about 15% copper average, while the remainder is low-grade ore of about 7% average. We call it low-grade; the Americans call it very high grade. About 25% of this remainder will, when subjected to concentration, yield concentrates of about 18% copper, which, added to the direct-smelting ore, will give 1,600,000 metric tons of 15.5% smelting ore and 4,400,000 metric tons of 6% low-grade ore, the average grade being over 8½% copper.

The work of investigating the reserves below the water levels on the Star and Luushia mines is being pushed ahead as the mining progresses. At Kambove also the investigation of the reserves in the next 100 ft. below the adit level—which is about 135 ft. above the bed of the dry Livingstone Creek—is being continued, and it was on this section of the mine that Mr. Gibb, as the result of his preliminary drilling work, estimated that there was about 3,000,000 metric tons of ore similar to that in the superficial part of the deposit.

Arrangements are being made to open up the Likasi and Chituru mines, which are close to the line of railway joining Kambove to the smelters. Mr. Adams in 1903 estimated that about 700,000 metric tons of 13% ore had been exposed in Likasi. Besides the mines already being exploited, there are, as you know, at least 150 copper deposits of importance—without including the mere copper prospects. . . .

SMELTING PROGRESS

The extension of the smelting plant is being continued. Two new furnaces will be erected this year and two further ones next year; these new furnaces are longer than the present type and are estimated to have a smelting capacity one-third greater than the present ones in use, so that the completed 7-furnace plant should have a capacity of 1000 metric tons of high-grade ore daily and an annual output of over 40,000 metric tons of metal and matte. The present ore and flux reserves opened up at the Star, Luushia and Kambove mines estimated for end of 1914 will keep this plant supplied, according to the present program, to about the middle of 1920. The gradual improvement in smelting costs and smelting conditions is very satisfactory, as shown by the following figures:

	1912	1913	1914
Furnace days worked.....	171	443	671
Charge per furnace day, metric tons.....	178	198	212
Total charge smelted, metric tons	30,280	87,800	143,670
Total output, metric tons...	2,510	7,410	10,720
Average cost per ton of fuel	£9 13s. 6d.	£5 17s. 6d.	£4 9s. 6d.
Average cost per ton of flux	15s. 6d.	9s. 2d.	8s. 11d.
Average cost per metric ton of product at smelting works	£47 12s. 0d.	£30 18s. 6d.	£29 12s. 10d.

The successful carrying on of the exploitation of the Katanga copper deposits is largely dependent on the development of the scheme for low-grade ore treatment. The large amount of work being done in various copper districts on the electrolytic-leaching treatment of such ores and the results of our own work in this direction in Katanga promise a very interesting future for our mines. It may be pointed out that the product resulting from this treatment is electrolytic copper, and does away with many of the difficult problems attendant on the smelting of ores, and will also probably considerably reduce the labor requirements compared with smelting. Mr. Wheeler is now out in Katanga for the purpose of working out the details of the low-grade ore treatment. . . .

From the annual reports will be noted the steady increase in the yearly production of copper from 997 tons in 1911 to 10,722 tons for 1914, and 6900 tons for the first six months of 1915. We estimate the total production for this year at something over 14,000 tons, and for 1916, 25,000 tons, and for the following years 40,000 tons per annum.

Forty-three of the staff of Union Minière du Haut Katanga have joined the British or Belgian forces, but notwithstanding this and numerous other difficulties arising out of the war, the company had a fairly good year in 1914, and now has increased smelting facilities and the benefit of greatly improved price for its product.

Strontium in the United States

According to the Geological Survey, no strontium was reported as mined in 1914 in the United States. It is estimated that at present not over 2000 tons of strontium-bearing minerals are needed annually to meet the requirements of the trade. This is because of the fact that, aside from a very limited use in drugs, strontium finds practically its sole use in the manufacture of fireworks and night signals used by railway and steamship companies. The *Journal* has already had an article on the possible use of strontium in the manufacture of beet sugar, but so far the process has not been taken up by any of the Western sugar refiners.

United States Borax Production in 1914

The production of crude borax materials in the United States in 1914 was 62,400 tons, as compared with 58,051 tons in 1913, according to the Geological Survey. All of the crude borax material now used in this country is the mineral colemanite.

The product was obtained from three mines, all in southern and southeastern California. The largest producer is the Pacific Coast Borax Co.; the second largest, the Sterling Borax Co.; and the third, the Stauffer Chemical Co., of San Francisco.

Details of Practical Mining

Clinton Mine Switch

The heavy motors and large cars now common in mining operations will not run safely or satisfactorily over the old switches made by the ordinary mine blacksmith, and where antiquated methods of switch-point construction prevail, all the long-standing troubles and expensive upkeep are present. The Clinton Switch Co. of Clinton, Ind., has developed a latch for a switch point which effectually locks it in position and does away with all the old-time rivets, bolts, spikes, etc., which always cause so much annoyance. This latch is shown in the cut. *A* shows the base plate with slot for web and undercut bottom for rail base; *B* the slide plate, and *C* the base plate in position.

The flat rounded base, or pivot lug on the butt end of the latch, fits into and interlocks with the base plate. The base plate is undercut on the bottom to fit over the

NEW MINE SWITCH POINT AND LATCH

base of standard rail and slotted to receive the web. The base plate has four spiked notches for fastening it to the ties. This method of construction allows all necessary motion of the switch point, but makes imperfect alignment impossible. The slide plate, which is also notched for spikes, furnishes a good bearing for the point end of the latch. In laying these latches, the slide plate is placed inside of and close to the bridle lug of the latch and not at the point. This gives a broader support for the latch precisely where the weight of the car or motor falls. The tire of the wheel, being at least 3 in. in width, is supported by the adjacent rail until well past the bridle lug. This latch, known as the Clinton latch, was developed to meet the requirements of the first Indiana mine to adopt all-electric hauling, and has given results much better than could be obtained from the old-style switch point.

How To Make Blueprints from Opaque Originals*

A method for making blueprints from catalogs or from drawings on thick, heavy, opaque paper is as follows: Lay the drawing, face down, on the glass of the printing frame, soak well with benzine; lay the blueprint paper, back down, on the face of the drawing and soak that with benzine; close the frame and expose to the sun in the usual manner; open the frame and wash the print in water, then hang the drawing and the print until they are dry. The print looks funny until all the benzine has evaporated, but in half an hour nobody would suspect that drawing and print had been in a bath of benzine—they are both opaque and in good condition.

The reason for placing the back of the blueprint paper against the face of the drawing is to lessen the displacement if the frame should not be set square to the sun's rays, as the shadow is "cast" through the thin blueprint paper instead of through the thick drawing.

Elevating Placer Tailings with a Hayward Bucket

By Hubert I. Ellis*

Hydraulicking in the interior of Alaska and the Yukon has been confined largely to the bench gravels. Where the deposits in the present stream channels have been hydraulicked, it has been necessary in most cases to elevate the gravel at some stage of the process. The usual method has been to dispose of the tailings by means of water, using the hydraulic elevator, as is the practice at Nome and elsewhere, or by simply driving the tailing up into piles, as has been done at Circle. The Yukon Gold Co. formerly used an entirely different method at Dawson, elevating the gravel to the sluice boxes instead of sluicing first and then elevating. The material was driven by giants to the desired points and raised by means of a system of steel-bucket elevators to an elevated sluice. Costs were such that when it was found practicable to dredge the ground, this interesting experiment was abandoned.

Where it is so difficult and expensive to develop an adequate water supply as it is in the region under discussion, it would seem preferable to elevate the tailings mechanically. This has been done successfully by means of a Hayward clam-shell bucket at a plant recently installed by Elmer Middlecoff on Highet Creek, in the Stewart River district, Yukon Territory.

The gravel deposit is 20 ft. deep. Water is delivered to a single hydraulic giant under a head equivalent to 150 lb. per sq.in. pressure. All the material is driven by the giant into a bedrock flume and sluice. The drain or flume is made of sheet steel and is 300 ft. long. Flat rocks and plank are used for riffles. Work progresses upstream by stages, the lower end of the flume being taken up and removed to the head as soon as the lower portion of the face has been sluiced.

The novel feature of the plant is found in the method of disposing of the tailings. A 1½-ton Hayward clam-shell bucket, set at the lower end of the sluice is used for this purpose. Power is furnished by a 20-hp. boiler and a 30-hp. engine. The bucket has a capacity of ¾ cu.yd., and the machine can handle an average of 1 cu.yd. of tailings per minute, which is ample for the present capacity of the plant. A sump into which the sluice discharges is first dug by the bucket, and the tailings are removed as fast

*4352 Ninth Ave., N. E., Seattle, Wash.

as they accumulate. The digger has a 75-ft. boom, and when handled properly it can throw the gravel 150 ft. from the sump. The tailings are stacked on one side only.

On the average 8 to 10 men are required to run the entire plant. Last summer 50,000 sq.ft. of bedrock was stripped, corresponding to 37,000 cu.yd. of material handled, so this method of solving the everlasting tailings problem has passed the experimental stage here. No figures relating to costs have been made public, but the operators express themselves as well pleased with the results of last summer's operations.

Aurora's Change House

By William Spence Black*

A new change house has recently been erected at the Aurora Consolidated Mines Co.'s camp at Aurora, Nev. The design and equipment of this house embody a number of new features, and there are several radical omissions. It was the desire of the management so to design and equip the building that it might at all times be kept clean and sanitary. With this in view it was found necessary to make a number of departures from the conventions. While in some cases these changes and omissions will be criticized, they were found to be essential if thorough cleanliness was to be attained.

Accommodations for two shifts of 100 men each are provided. The dimensions and general arrangement of the building are as in the drawings, Fig. 2. The floor

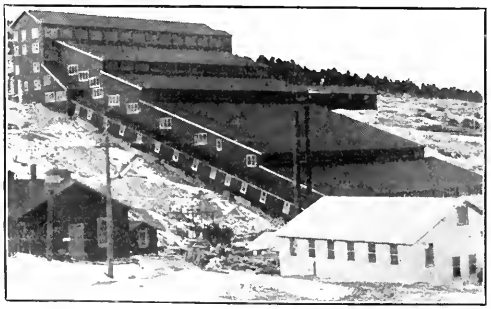

FIG. 1. AURORA CONSOLIDATED'S ASSAY OFFICE, MILL AND CHANGE HOUSE

is of finished concrete and is laid on a slight grade so as to drain to the center from all sides. The walls are boarded both inside and out, the outside walls and also the roof being further covered with corrugated galvanized iron. In the interior the ceiling and walls are lined with flat sheets of galvanized iron, No. 26 gage, 30x96 in. so that with the cement floor it is possible to flush out the interior with a hose. The showers, of which there are six, each with hot- and cold-water connections, are in the center of the building. The hot water is supplied from a 500-gal. tank heated by a steam coil, placed above the ceiling. The showers are inclosed by a partition of corrugated iron which is 6½ ft. high and which stands 1½ ft. from the floor. On one side of this partition is the entrance to the showers, and on the other three sides are wooden sinks with wash basins and hot- and cold-water taps.

*Manager, Mobile mine, Jean, Nev.

No lockers are provided. In their stead open suspended racks are used. There are four of these racks, two on each side of the building, as shown. Each shift has two racks, one on each side; this separates the men and prevents unnecessary crowding. The construction of the racks may be readily understood from the drawings (see Fig. 2). The main frame is a rectangle of ¾-in. wrought-iron pipe, 4 ft. high and 45 ft. long. This is stiffened by six pieces of ½-in. pipe placed in the main frame at regular intervals. All joints are oxyacetylene welded. The wooden frames of the separate compartments are attached to this main frame by means of U-bolts. Small-mesh poultry wire is used to divide the compartments, and is attached

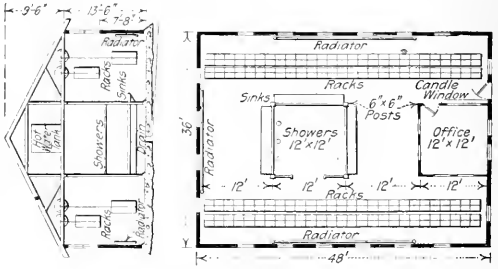

FIG. 2. PLAN AND ELEVATION OF THE AURORA CHANGE HOUSE

by means of staples and wire. Each rack contains 54 compartments, 27 on each side. These compartments are 48 in. high, 20 in. wide and 12 in. deep, and have hooks placed around the top. A bottom is provided by screwing 1½x¾-in. slats along the under side of the frames.

The racks are suspended by ½-in. braided cotton ropes from steel shafts. This shafting is 1½-in. diameter and is mounted above the ceiling. The ropes pass through narrow slots cut in the ceiling and are then attached to the shafting by means of collars and setscrews. At one end of each of the shafts a 3-ft. pulley is mounted, and a 6-in.

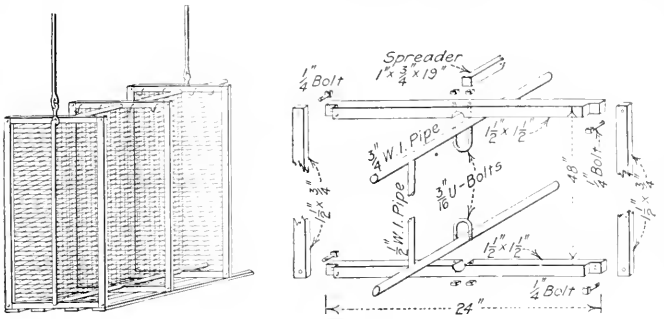
COST OF AURORA CHANGE HOUSE

	Supplies	Labor	Total
Grading	.....	$106.96	$106.96
Foundations and floor	$262.06	64.50	326.56
Construction:			
Lumber	$590.80		
Doors and windows	58.08		
Galvanized iron, interior	295.13		
Galvanized iron, exterior	662.30		
Painting	57.84		
Miscellaneous	11.28		
	1675.43	626.58	2302.01
Racks	165.55	204.66	370.21
Plumbing	119.49	180.72	300.21
Heating	196.40	139.83	336.23
Electrical	33.22	43.64	76.86
Total	$2452.15	$1366.89	$3819.04

pulley, in line, is attached to the wall a few feet above the floor. A manila rope is run belt-wise over both pulleys.[1] To prevent slipping, a continuous row of staggered iron teeth, made from ¼-in. round iron, is placed around the face of each pulley. These teeth slope toward each other, forming a V-shaped groove in which the rope runs. The staggering of the teeth causes a continuous crimping of the rope as it passes over the pulleys, thus greatly increasing its grip. In order that the rope may be kept tight, the lower pulley is mounted in a vertical slot in which it may be moved up or down by means of a

[1]Some style of light sprocket chain would probably be more satisfactory for the hoisting mechanism on the racks, for the strain and wear on a rope are considerable.

threaded rod, thus allowing adjustment of the rope tension. A detachable crank and a ratchet on the lower pulley complete the equipment. By means of this arrangement the rack may be hoisted out of the way and beyond the reach of curious fingers while the shift is on, and be lowered again when the shift comes off.



LOCKER DETAILS, AURORA CONSOLIDATED

As far as cleanliness goes these suspended racks should speak for themselves. They are entirely open and can be readily flushed off if desired. They have no dark corners or shelves on which old clothes and dirt can accumulate, and they are wholly open to both light and air. Furthermore, they take up but little floor space. In fact, on equal floor spaces it is possible to give almost twice the number of accommodations in suspended racks that can be given with the usual style of stationary lockers. Omitting the office, there is an area of 7.92 sq.ft. per man. This figure is lower than the average for change houses, but when one realizes that it is practically all available, its value is considerably increased. No toilets or urinals are provided within the building, an omission which is in line with the policy of thorough cleanliness.

The building is steam-heated. Three radiators are used, one on each side and one across the end. The steam is supplied from the company's boiler house, about 100 ft. away.

A summary of the cost is given herewith. All supplies are brought in from Hudson, on the Nevada Copper Belt R.R., which is 60 mi. from the camp.

New Electric Blasting Caps for Wet Work

When blasting by electricity and there is little water encountered, satisfactory results will be obtained by using the ordinary type of electric blasting caps. When a considerable quantity of water is found in the bore holes, it is more economical to use electric blasting caps that are made for this special condition. The reason for this is that the cotton insulation on the wires of an electric blasting cap only furnishes protection to the wires from abrasion and slight protection from water, the water easily penetrating the cotton insulation, causing short circuits and consequently misfires.

Because of varying water conditions there have been placed on the market two kinds of Du Pont electric blasting caps to meet the demands and also to furnish the consumer with an electric detonator which can be used under the most severe conditions.

The construction of these electric blasting caps is the same so far as concerns the detonating charges, wires, cotton insulation on wires and filling material above the detonating charge. The difference will be found in the length of the copper shells, insulation under cotton insulation, and gutta percha covering the copper shells and extending about 2 in. up the wire.

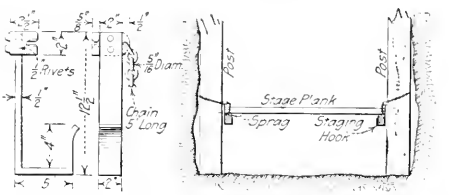
The increasing use of electric blasting emphasizes the importance of watching the condition of all leading and connecting wires and blasting machines to see that all are kept in good condition and that connections are well made.

Avoid kinking wires as this leads to cracks and breaks not easily detected through the insulation. Don't drag wires over the ground as this scrapes off the insulation. Test the blasting machine with the rheostat at regular intervals to see that it is working up to capacity. Test all circuits with the galvanometer before attempting to blast. These are simple precautions.

Safety Staging Hook

By D. E. Charlton*

This hook was designed to take the place of the old-style hook that was driven into the post. The tendency of the old hook was to pull out at times, and it could only sustain a limited weight. Its subsequent removal from a post into which it had been driven required considerable effort.



SAFETY STAGING-HOOK, DETAILS AND IN USE

These staging hooks have been successfully used for some time by the Oliver Iron Mining Co. in its mines on the Mesabi Range. Four constitute a set and are used two on either side in the drifts where timber sets are placed and stagings are required for repairing or drifting ahead or stoping. The chain is wrapped about the post, the hook elevated to the required height and the loose end of the chain placed in the slot on the opposite side of the hook from which the chain is fastened. The slot is so made that the hook will not slip if the chain is placed tightly around the post and the first link, beyond that required to encircle the post, is placed in the slot. Hewn timbers, planks or sprags may then be placed in the hooks and the staging planks on top of them. Protruding ends of rivets will dig into the post when weight is applied and tend to steady hook and staging. The accompanying sketch shows the detail of the hook and the method of application.

Details of Milling and Smelting

Dwight-Lloyd Sintering Practice at Salida, Colo.

The Ohio & Colorado Smelting Works at Salida, Colo., was one of the first to adopt the Dwight-Lloyd sintering machine, and while the management went through the usual experience that falls to the lot of beginners with a new process, it also had the pleasure of seeing the blast-furnace capacity increase, in the case of the 48x180-in. furnaces, from 180 to 250 tons per day for long periods.

The roasting plant at present consists of three Godfrey furnaces, 26 ft. in diameter, with a capacity of 25 tons per day each; one Wedge furnace, 21 ft. in diameter, with a capacity of 75 tons per day; four Dwight-Lloyd machines, 42x264 in., with a capacity of 80 tons per day each. The Godfreys and Wedge are used for preliminary roasting before sintering on the Dwight-Lloyd machines, the sulphur in high-sulphur ores being reduced to a point where the product can be added to the Dwight-Lloyd charge without raising the sulphur above 15% on the unroasted charge. These furnaces are served by a 468-ft. flue, having a cross-sectional area of 166 sq.ft., and joined to a stack 85 ft. high, 12 ft. in diameter. The volume of gases discharged is approximatly 125,000 cu.ft. per minute.

It must be borne in mind, writes F. D. Weeks[1], that this Dwight-Lloyd sintering plant was built when there were no plants to serve as guides. The original charge measuring and mixing apparatus is still used, although many accessories have been evolved since the construction of the plant. The charge is made up from six bins with belt bottoms discharging onto a belt that delivers the charge to the center of a cast-iron revolving table. The charge is moved to the edge of the table by fixed plows, water being added during the time of plowing; then it is scraped off into ore cars, sent to the top of the building on a platform elevator and dumped into the machine feed bins. The use of a platform elevator instead of a bucket-and-belt elevator was decided on after seeing the segregation that took place when a belt elevator or conveyor was used. This stopped the segregation of coarse charge along the edge of the pallets.

For a long time coarse charge was fed to the pallets by means of an extra hopper behind the regular feed hopper, but it was found that if the back of the regular hopper was removed and the feed regulated to a thin stream, all the coarser particles would roll to the grate and stay there, stopping grate leakage and leaving only fines on top, presenting a proper surface for ignition. Coal ignition is still used because gas is not available and, with a wooden structure, gasoline is feared.

An important improvement has been made in the construction of the machines by placing an adjustable rail by the side of the pallets so that the weight of the loaded pallets is carried on the rollers and not dragged across the top of the windbox causing excessive wear. The height of the rails is adjusted so that, as the top of the windbox wears, the rails take the loads. This arrangement leaves no appreciable space between the bottom of the pallets and the top of the windbox.

The Dwight-Lloyd product falls into side-dump railroad cars and is taken to smelting beds. Local conditions necessitate frequent changes of charge, so the sinter is spread on smelting beds instead of being smelted separately.

[1]Excerpts from a paper entitled "The Salida Smelter," to be presented at the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

Storage of Powdered Coal*

Anthracite offers practically no difficulty in the way of storage, as it is almost unaffected by weather conditions and it will not ignite spontaneously. Bituminous coals, however, when stored, disintegrate and are in great danger of spontaneous ignition.

This is due to an absorption of oxygen from the atmosphere by the coal itself. If the heat resulting from this reaction can be dissipated, no harm results; otherwise the temperature of the coal rises until the temperature of ignition is reached. The area of the surface exposed is a determining factor, and since this surface area is increased as the size of the particles is decreased, we can readily imagine the importance of this when applied to powdered coal.

Dennstedt and Schaper in *Zeit. f. angew. Chem.*, 25, 2625-9, show that the greater the percentage of oxygen in the coal, the more liable it is to ignite spontaneously.

Porter and Taylor in *Journ. Ind. Eng. Chem.*, 5, 292, state that "the development of heat on moistening dry coal . . . may contribute appreciably to the spontaneous heating of some coals in storage."

These opinions indicate two factors in the spontaneous ignition of powdered coal—the presence of oxygen and other occluded gases and the presence of moisture. Other causes of self-ignition are: 1. Pressure on the coal. 2. Presence of iron pyrites. 3. Volatile matter in the coal itself. 4. Temperature.

The effect of pressure is to increase the temperature of the pile of coal, and it varies as the height of the pile. It is suggested that the pile should never exceed a height of 12 ft.

The effect of iron pyrites is rather doubtful, as coals containing negligible quantities of this compound have been known to ignite spontaneously.

Coals which are fairly high in volatile matter are more subject to self-ignition. This has been fully borne out by the findings of Messrs. Tessenden and Wharton (*Bull. Univ. of Mo. Eng. Series*, Vol. 1, 1908).

The effect of temperature is considered by many authorities to be one of the important factors in spontaneous combustion, because the oxidation proceeds more rapidly

*Abstract from article in "Coal Age" of July 31, 1915, by Edward J. Kelly.

as the temperature of the coal increases. Heat from the sun's rays may even be dangerous, an instance of this kind having occurred in the surface works of the Mayback colliery at Friedrichstahl, Germany. Floating coal dust deposited on some of the iron girders in layers of an inch or more, and was burned to a white ash when the girders became heated by the sun.

The following precautions should be observed in storing powdered coal: 1. Limit the height of the coal pile to 10 or 12 ft. 2. Isolate the coal from all sources of heat such as steam pipes, flues, reflecting surfaces and direct sunlight.

In regard to the conditions of storage, two different methods may be cited: 1. Storing in piles in the open air. 2. Storing in covered bins.

There seems to be very little to choose between these methods, save that all other things being equal, the covered bin would protect the coal from direct sunlight, which was shown to be a contributing factor in spontaneous ignition. If covered bins are used, added overhead charges will be entailed, while open storage on the other hand gives low costs.

I have been informed of a novel storage bin constructed for a firm in Maine. This bin contained several rows of upright beams. Saw-tooth projections were built on two sides of each upright, thereby forming air-spaces, which led into the main flue, the latter extending from the bottom of the bin to the top. When the bin was filled with coal, the heat generated and the gases given off escaped through the flues to the top of the bin and out into the air. It is perfectly obvious, however, that should the coal in the bin become ignited by any chance, the flues would produce a draft and so increase the rapidity of the combustion.

Bins should be constructed of stone, brick or concrete; if iron work has entered into the construction, it should be covered with concrete.

Radiation Pyrometers

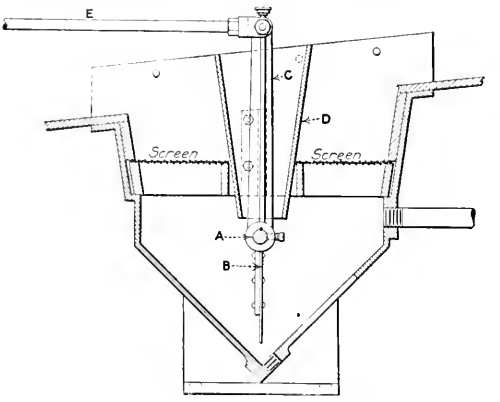
"Characteristics of Radiation Pyrometers" is the title of a paper recently published by the Bureau of Standards of the Department of Commerce, giving the results of careful study of this type of temperature-measuring instrument. Such a study was considered urgent on account of the extensive use of radiation pyrometers in the technical industries. These instruments are widely used in the temperature control of the various processes involved in iron and steel manufacture, alloy foundry work, glass, ceramics and brick manufacture, smelting, gas works, steam generation, etc.

Many of the instruments examined show different temperature readings for different focusing or sighting distances. Errors thus occasioned may amount to several hundred degrees. The effect of dirt upon the lenses and mirrors is of serious importance. The question as to whether the pyrometer absorbs all the heat radiation falling upon it is discussed, and the theory of the instrument and the connection of the behavior of the pyrometer with the theoretical radiation laws are given.

The bureau receives a large number of these instruments for test and standardization from various technical industries located throughout the country. Heretofore this testing required about three days for a single instrument, on account of the difficulty in heating a furnace to an exactly uniform temperature. A new method has now been developed which permits a satisfactory standardization of a radiation pyrometer within one hour. Many suggestions are given for minimizing the errors to which the pyrometer is subject, and it is shown that this type of instrument, suitably designed, adequately calibrated and correctly used, is a trustworthy pyrometer, having many advantages over other types of temperature-measuring devices, both for scientific and technical use.

Neill Jigging Apparatus

James W. Neill, of Pasadena, Calif., has patented (U. S. Pat. 1,141,191) a jig in which the pulsation is supplied by a paddle directly connected to the operating shaft, the object being to provide a more compact mechanism and to save floor space that otherwise would be taken up by



NEILL JIG WITH PADDLE PULSATOR

the rocker arms and link. A sectional view of one form of the apparatus is shown in the accompanying illustration. Mounted on the shaft *A* is a paddle or blade *B*, integrally connected with an upper extension *C* in the casing *D*. To this upper arm *C* is attached a connecting rod *E* in any desired manner to cause the proper oscillation of the paddle.

Prevention of Hot Tops in Blast Furnaces

A novel idea for the prevention of hot tops in blast furnaces is described by William D. Kilbourn, of Tooele, Utah, in U. S. pat. No. 1,148,782. The method consists in coating the fuel with a nonoxidizing fusible coating, which prevents the carbon from catching fire too high in the furnace. Preferably this coating is made of a compound of the metal to be smelted. For instance, in lead blast furnaces the patentee says a very suitable coating is a mixture of lead sulphate, lead oxide and a varying percentage of impurities, the mixture to contain about 60% of lead. It is claimed that the method prevents bad accretions at the tuyere line and helps to make a hot slag and to get a better settlement of the metal because of the added heat.

The Assayer and Chemist

Heusser Multiple Weight Attachment for Chemical Balances

By Wilfrid Heusser*

This balance was designed in response to a general demand for a time- and labor-saving weighing instrument. The tedious task of picking up and placing small weights upon the balance pans and arresting the balance each time for the purpose is eliminated.

With reference to the accompanying illustrations, the pan hanger on the right side carries a perforated plate or grid. Back of this pan hanger a short column is solidly mounted upon the base-plate, carrying nine movable levers. The front end of each of these levers

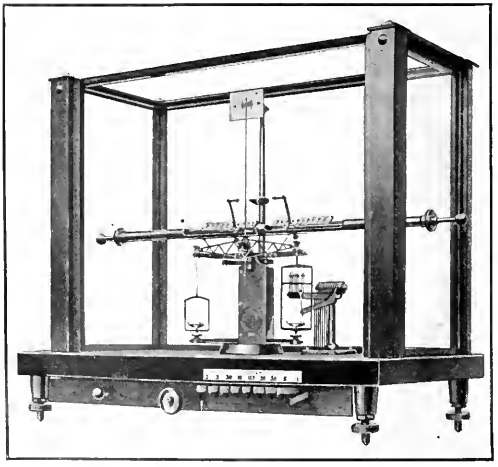


FIG. 1. GENERAL VIEW OF HEUSSER BALANCE

has an upright conically tipped staff, which moves centrally and vertically through the perforations of the grid.

The levers are operated from the outside by means of depressible push keys arranged similarly to a typewriter keyboard and located in front of the balance.

The illustration, Fig. 1, shows eight levers in their uppermost position with the weights at rest, and one lever depressed with its weight deposited upon the grid.

The weights are in the form of disks, each disk having a central perforation. At rest they are supported by means of the conically tipped staffs, which extend partly into the perforations. When in use they are deposited in countersunk holes in the grid. These weights may be deposited and again picked up independently of each other, and the balance-beam is free to swing, by simply pushing the depressible keys up and down.

*Balance manufacturer, Board of Trade Building, Salt Lake City, Utah.

The value of each weight is plainly marked upon an index plate placed above the keyboard, and the possibility of making mistakes is positively excluded.

The capacity of the weights for assay balances is 221 mg. and is divided into 1, 2, 3, 5, 10, 20, 30, 50 and 100 mg. For extremely delicate weighings where the ½-mg. rider is used, the capacity is only 110 mg.

Since the majority of assay buttons will come within this range, the handling of weights with tweezers is

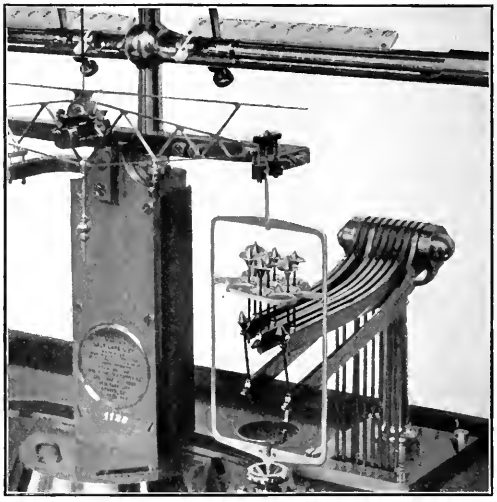

FIG. 2. DETAILS OF WEIGHT-HANDLING ATTACHMENT, HEUSSER BALANCE

almost entirely eliminated. These balances will save 50% of the time consumed in weighing with an ordinary balance, and for assay offices where considerable weighing must be done, this may amount to a great deal.

For analytical balances the weights are 10 times heavier, or 2210 mg. in all. This balance is sold by the Mine & Smelter Supply Co., of Salt Lake City, Denver and El Paso.

*

Assaying Lead Bullion at the Salida Smelting Works

A plan to eliminate the personal equation in bullion assaying has been carried out with good results for some years at the Ohio & Colorado Smelting Works, Salida, Colo., according to E. D. Weeks[1]. The "gum-drop" samples, weighing about ½ assay ton each, are weighed without trimming, cupelled and parted; the weights of the gum-drops in decimals of an assay ton of the gold

[1]Excerpt from a paper entitled "The Sallda Smelter," to be presented at the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

and silver together and of the gold alone, in milligrams, are reported by the assayer. The calculations are then made in the office on a machine. In this way the assayer is not tempted to make his results check, because until they are figured he does not know whether they will check or not. The excellent results obtained are sufficient reason for following the plan.

Platinum in Litharge*

The news of platinum finds going through the papers not long ago owe their origin probably to a surveyor by the name of Schreiber who died about one and one-half years ago. He pretended to have discovered a new method of determining platinum in rocks by which occurrences of platinum heretofore not provable—chiefly in colloidal form in the rocks—became determinable. Without going further into the value of this Schreiber method I desire to mention that investigations of ores were undertaken by other parties by which also a trifling amount of platinum was found in rocks that actually contained no platinum.

The Schreiber platinum finds were thus apparently confirmed and great expectations were based upon them in lay circles, creating something like a platinum rush. The incorrect results of these investigations may be in part accounted for by the use of not altogether unobjectionable reagents in the platinum determinations, particularly the use of platiniferous litharge.

Basis of the Westphalian Platinum Excitement

The examination of litharges for their contents of precious metals carried out by the author 10 or more years ago unfortunately did not include the determination of any platinum that might have been present then. It is, however, doubtful whether it could have been proved in those days. At any rate during the last 10 or 15 years the possibility of finding platinum in litharge has become greater through the introduction of jewelers' sweeps for the recovery of their precious metals into custom works producing litharge.

The content of platinum (or of any other precious metal) in the litharge will, of course, vary according to the time the sample is taken, whether in the beginning or at the end of cupellation, or whether it is from lead rich or poor in precious metals. The investigation of the various samples of litharges was made as follows: Separate weighings of 62.5 grams of litharge were each mixed with 15 grams of flour and a flux consisting of 3 parts c.p. sodium carbonate, 3 parts of c.p. potash, 1.5 parts c.p. borax and 1.5 parts c.p. table salt, and reduced to metal in a Hessian crucible. The lead buttons of the same class were concentrated in a scorifier, the result of 8 weighings (equivalent to $\frac{1}{2}$ kg. of sample) being obtained in one single lead button which was run down in a cupel of pure bone-ash. In the resulting bead, platinum, gold and silver were determined in the customary way.

The Freiberg litharge showed the largest differences in precious metals as it consisted of the well-known large scales which even by the most careful mixing do not yield a uniform result. The two other samples of litharge were ground fine and showed hardly any differences. There were contained on an average in 1 kg. of litharge:

	Platinum Mg.	Gold Mg.	Silver Mg.
(1) Litharge from Freiberg.....	0.417	0.916	25.33
(2) Litharge from Frankfurt a/M..	0.350	1.350	11.22
(3) Litharge from Muilheim.....	0.111	0.666	10.00

The results thus obtained were not the totals of precious metals of the samples of litharge examined. On further test the litharges obtained in the scorifiers still gave notable amounts of platinum, gold and silver. Thus 1 kg. of this litharge showed:

	Platinum Mg.	Gold Mg.	Silver Mg.
In (1)	0.123	0.200	5.988
In (2)	0.060	0.362	2.666
In (3)	0.034	0.142	2.446

A further investigation of the litharge obtained in this last scorification was not made, but it would surely have yielded still more precious metals.

*From an article by F. Michel of the Grand Ducal Assay Office at Pforsheim, Baden, in "Chemiker Zeitung," Jan. 2, 1915.

To Cut Glassware Easily

By E. J. Hall*

Of the many methods proposed for cutting bottles there is but one which is satisfactory in the average laboratory worker's hands, namely, the electrically heated wire. A description of this method was published several years ago, but since it does not seem to be generally known, it will stand repeating.

To cut the bottom from a bottle, make a file mark at the desired point; wrap a strip of paper around bottle just below mark, to act as a guide, and encircle bottle with a piece of resistance wire, being sure that the wire passes over the file scratch. Iron wire may be used, but B. & S. 22-gage nichrome wire is preferable. Where the wire passes itself it may be insulated with asbestos paper or simply held slightly apart. The ends of wire are fastened to suitable holders, mounted or held in the hand. In the latter case, the holders must be insulated. A resistance must be placed in the line, and if none is at hand, the following will answer perfectly: Make a 5 to 15% solution of almost any salt—sodium carbonate is satisfactory—and connect to the two ends of a break in the line metal, or to carbon rounds. By inserting these in the salt solution to different depths, or varying the distances apart, the current may readily be controlled. With everything in shape, turn the current on and increase it until the wire, which should be held taut and in close contact with the bottle, shows red—10 to 12 amp. is usually sufficient. The free ends of wire will glow brightly; in about 30 sec. there will be a sharp snap, when the bottom may be lifted off. On rare occasions it is necessary to give the glass a tap with a light instrument.

This is one method which works as well as it reads. Five-gallon water bottles are cut as readily as a test tube, and watch glasses or other glassware, where the wire can be held in contact with the surface, are split with equal facility, the break following true to the contact of the wire.

A Piece of Thin Sheet Rubber Fastened over the Top of a Büchner Funnel by means of a rubber band will prevent the formation of cracks in the precipitate and greatly facilitate the removal of the mother liquor when filtering by suction, according to R. A. Gortner ("Journ. Am. Chem. Society"). The suction draws the rubber down into close contact with the precipitate, and a vacuum of 15 mm. can easily be obtained within the flask.

Correspondence and Discussion

Recovery of Zinc from Cyanide Precipitates

Owing to the present high price of zinc we, in the cyanide business, are wondering whether some scheme could not be worked out to recover the excess zinc from the press or zinc-box precipitates.

About a year ago Dr. G. H. Clevenger proposed a scheme of retorting which did not look good to me, from a commercial standpoint, considering the then low price of zinc.

In several plants they subject the precipitate to a sulphuric-acid treatment to dissolve the excess zinc before smelting. This gives zinc sulphate in solution. Would it be possible to precipitate the zinc from the sulphate, and by what methods? Several methods have been tried, but I understand they have been unprofitable when zinc is selling around 4c. per pound.

As zinc in the shape of dust or shavings is selling at a high figure at present, some of the older schemes of zinc recovery from solution or by retorting may now prove profitable. If zinc recovery could be effected from cyanide precipitate, it would mean a great saving to cyanide operators throughout the world.

CARL J. TRAUERMAN.

Landusky, Mont., Aug. 4, 1915.

[We think that Doctor Clevenger's paper on the distillation of zinc from cyanide precipitate is the best contribution upon this subject in existence. Zinc may be recovered from the sulphate solution by evaporating the solution and calcining the sulphate, or by mixing the sulphate with a proper proportion of zinc sulphide and calcining. As a precipitant, calcined magnesite would probably be the cheapest of the common agents that are available. The precipitate would be zinc oxide. In any of these cases, the zinc oxide would have to be distilled in order to obtain metallic zinc. We doubt if such a process would be profitable in connection with a gold-extraction works. The distillation of excess metallic zinc from the precipitate ought to be feasible, however. We hope that our readers will join in a discussion of this subject.—Editor.]

Fineness of Crushing for Assaying

The primary cause of differences in assays, noted by A. A. Nason in the *Journal* for Aug. 7, resulting from differences in the mesh to which the ore is crushed, lies in the fact that modern assaying has fallen under the domination of the "rule o' thumb." Fundamentally this condition rests upon the overwhelming tendency of modern education to store the mind instead of training it. In rating United States Civil Service examination papers it is common to find the same flux, often a stock mixture, used for quartz and for limestone and even for roasted pyrite. Incidentally the condition is in part due to the present insane speed mania. Speed has its uses, but it is full of dangers.

Under the "rule o' thumb" it is perfectly logical to find a maximum-extraction degree of fineness for crushing ore. Lower extractions from either coarser or finer mesh are both due to the same cause which results from opposite conditions in the two cases. It is fundamental in crucible fusions that the reduced lead should remain in contact with the fusing ore particles a sufficient length of time to absorb thoroughly the precious metals of the ore. With too coarse a mesh the fusion is slow and the lead sinks to the bottom before fusion is complete. With too fine a mesh the fusion is too rapid and the reduced lead sinks through the liquid charge before it has had sufficient time to extract the precious metals.

Because the attempt to oxidize sulphides in the crucible by means of niter so often leads to boiling over the charge, objection is sometimes raised to it, and the fact is lost sight of that a certain amount of boiling is essential to the success of the fusion. Consequently the conditions favoring the boiling of the charge are often unwisely reduced to the minimum, and the fusion may be completed without a sufficient amount of boiling. Under-boiling is really more objectionable than over-boiling, because the latter shows itself and we know the fusion is ruined and must be rejected; but we have no evidence in the charge itself when it is under-boiled, and such a faulty fusion may easily be accepted.

There is widespread neglect of the physical effect of bicarbonate in the fusion. My old and beloved instructor in assaying, the late Prof. O. D. Allen, used to speak of the bicarbonate as a "rod." Just as wet work required a rod to mix properly the contents of a beaker, so a proper fusion required the mixing of the charge when melting down and this must be secured by the proper evolution of the CO_2 from the bicarbonate. In my own practice I use made-up fluxes sparingly, and as a rule intentionally leave some of the bicarbonate in small lumps for the purpose of prolonging and equalizing the evolution of CO_2.

Finally, if one is obliged to assay very finely ground ore I would repeat the suggestion I gave in the Oct. 19, 1912 issue, to use a retarder of fusion, such for instance as 100-mesh bone-ash.

FREDERIC P. DEWEY, Assayer,
Bureau of the Mint.

Washington, D. C., Aug. 11, 1915.

Platinum in California

I have read with much interest the article on "Platinum in California" in the *Journal* of June 12, 1915, p. 1045.

The tests made on the Long Tom ore as described and the results obtained are identical with an experience I had testing a sample of iron pyrites for platinum by the same qualitative tests outlined by Lodge in his "Notes on Assaying."

I made two tests, one on the ore and the other on a piece of platinum wire, and obtained a strong cherry-

red color in both tests which I supposed was caused by platinum iodide. Later I proved by quantitative methods that the ore contained no platinum and decided my first test was faulty.

The encouragement the first test gave me was responsible for a considerable amount of work and expense in proving the ore and locating a mining claim.

As the *Journal* suggests that ferric chloride will give the red color to the iodide solution, it seems to me this test for the detection of platinum would be useless for ores containing iron, and nearly all ores have some iron in them.

I would like to learn of a simple and reliable qualitative test for the detection of platinum in ores containing sulphides. A discussion of platinum analysis in the *Journal* would, I believe, be of great interest to many readers.

A. L. Hawkins.

Lewistown, Mont., July 19, 1915.

[The *Journal* foresaw almost two years ago the coming need of knowledge of the chemistry of platinum and printed articles on that subject as follows: Dec. 20, 1913, p. 1175; Jan. 24, 1914, p. 229; May 16, p. 1007; June 20, p. 1249; Sept. 19, p. 530; Apr. 17, 1915, pp. 700 and 701. The fact unfortunately remains, however, that the platinum metals, more than other elements, seem to require working experience, and assaying directions do not suffice.—Editor.]

New Sampling Plant at Hamburg

It may perhaps be of interest to call attention to a statement from which erroneous conclusions might be drawn in the article, "New Sampling Plant at Hamburg," published in the *Journal* of July 24, 1915.

Referring to the results obtained by this sampling mill, it is stated in the article, "From careful tests made the results obtained have been extraordinarily accurate, with only a minute difference in the analyses from different bottles filled at the same time by this machine and representing the same parcel of ore."

A little reflection will convince one that the agreement in analyses from any two bottles filled at the same time is no more than an indication of the accuracy of the last device in the sampling plant—that is, the bottle filler. It gives no line whatever on the accuracy of the sample as a whole, which latter point could only be determined by passing the rejected four-fifths of the original lot again through the sampler and checking the bottle sample resulting therefrom with the bottle sample obtained in the first instance.

Furthermore I doubt if the general commendation of this German plant is particularly justified. The pyrites ore there received is homogeneous in character and represents perhaps the simplest known material to be sampled in mining practice. Samples taken with any ordinary degree of care should not be expected to vary materially, because of this homogeneity. There is a much greater probability of variations in the chemical analysis following. The expedient of a three-high train of rolls has been found one of doubtful advantage in this country, for the reason that it makes control, adjustments and repairs difficult. Because of the irregularity of feed, which in spite of the devices mentioned will nevertheless persist, the discharge is irregular, and I doubt if the reciprocating vanes described actually do secure an accurately representative sample.

In short, I doubt very much if this sampling mill would give comparatively good results on complex sulphide ore carrying precious metals such as are treated by many of our Western sampling plants.

Robert K. Painter.

New York City, Aug. 13, 1915.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

BLAST FURNACE—Francis J. Zippler, Avalon, Penn. (U. S. No. 1,147,475; July 20, 1915.)

CONCENTRATOR (Ore).—Orrin H. King, Wallace, Idaho. (U. S. No. 1,148,591; Aug. 3, 1915.)

COPPER AND NICKEL—A Process of Separating Copper and Nickel in Copper-Nickel Matte and Other Products. N. V Hybinette, Christiania, Norway. (Brit. No. 13,355 of 1914.)

CRUCIBLE POURING DEVICE—Metallurgical Implement. Charles F. Jacobs, Chicago, Ill. (U. S. No. 1,146,573; July 13, 1915.)

CRUSHING—Hammer Attachment for Rotary Mills. Milton E. Williams, St. Louis, Mo., assignor to Williams Patent Crusher & Pulverizer Co., St. Louis, Mo. (U. S. No. 1,147,351; July 20, 1915.)

DRILL—Rock Drill. Clarence A. Dawley, Plainfield, N. J., assignor to Ingersoll-Rand Co. (U. S. No. 1,148,760; Aug. 3, 1915.)

DRILLING—Improvements in or Connected with Rock-Drilling Machines. W. C. Stephens, Carn Brea, Cornwall. (Brit. No. 16,034 of 1914.)

DRILLS—Boxing for Drills. John A. Hallander, Ottumwa, Iowa, assignor to American Mining Tool Company, Ottumwa, Iowa, a Corporation of Iowa. (U. S. No. 1,148,313; July 27, 1915.)

DRILLS—Rotation Mechanism for Percussive Drills. Lewis C. Bayles, Easton, Penn., assignor to Ingersoll-Rand Co., New York, N. Y. (U. S. No. 1,148,649; Aug. 3, 1915.)

IRON—Process of Smelting Iron Ore. Florentine J. Machalske, Plattsburg, N. Y., assignor to American Ferrolectride Corporation, Plattsburg, N. Y. (U. S. No. 1,148,700; Aug. 3, 1915.)

LEACHING—Process of Precipitating Copper from Solution. George D. Van Arsdale, East Orange, N. J. (U. S. No. 1,147,466; July 20, 1915.)

MAGNETIC SEPARATORS—Improvements in Magnetic Separators. Stephan Bruck, Charlottenberg, Germany. (Brit. No. 20,552 of 1914.)

METAL RECOVERY—Process for the Recovery of Metals from Ores and the Like. Charles S. Vadner, Salt Lake City, Utah. (U. S. No. 1,144,402; June 29, 1915; and No. 1,146,373, July 13, 1915.)

POTASSIUM—Process of Treating Potassium-Bearing Minerals. Saul E. Melkman, Montreal, Quebec, Canada. (U. S. No. 1,148,850; Aug. 3, 1915.)

PULP SETTLER. Harry R. Conklin, Joplin, Mo. (U. S. No. 1,147,786; July 27, 1915.)

PULVERIZED-COAL BURNER. Norman Lew Warford, Anaconda, Mont. (U. S. No. 1,147,833; July 27, 1915.)

REDUCTION—Process for the Reduction of Metals from Their Ores by Carbon from Solid Fuel. William D. Kilbourn, Tooele, Utah. (U. S. No. 1,148,782; Aug. 3, 1915.)

REFINING—Electrolytic Refining or Extracting Process. Francis R. Pyne, Elizabeth, and Henry M. Green, Chrome, N. J. assignors to United States Metals Refining Co., Chrome, N. J. (U. S. No. 1,148,798; Aug. 3, 1915.)

ROASTED ORE—Method and Apparatus for Treating Roasted Ore. A. Ramen, Halsingborg, Sweden. (Brit. Nos. 15,254 and 15,378 of 1914.)

ROASTING—A New or Improved Process for Treating Ores or Other Materials in Roasting and Drying Furnaces. O. Spinzig, and Waldemar Hommel, Clausthal, Germany. (Brit. No. 8766 of 1914.)

ROASTING—Improvements in or Relating to Mechanical Roasting Furnaces. J. Claude, Frankfort-on-Main, Germany. (Brit. No. 10,058 of 1914.)

ROASTING—Improvements in or Relating to the Roasting of Ores Containing Sulphur Existing in the Free State, or as a Metallic Sulphide. A. D. Carmichael and H. S. Montgomery, Norwich, Conn. (Brit. No. 14,295 of 1914.)

SEPARATOR—Centrifugal Apparatus. Wilhelm Meyer, Johannesburg, Transvaal, South Africa. (U. S. No. 1,146,570; July 13, 1915.)

SLAG—Prevention of the Deposition of Slag in Furnaces. Robert Grabowsky, Hanover, Germany. (U. S. No. 1,147,163; July 20, 1915.)

SLAGS—Method of and Apparatus for Recovering the Heat of Slags. Carl Semmler, Wiesbaden, Germany. (U. S. No. 1,146,962; July 20, 1915.)

Mining on the Witwatersrand

JOHANNESBURG CORRESPONDENCE

SYNOPSIS—Decline in grade of ore is the rule on the Rand at the present time. Working costs are being reduced, but profits are also diminishing. The condition and prospects of the principal mines are discussed.

The general tendency on the Rand continues in a normal manner toward a further fall in the average grade of ore milled and a decline in working costs. During 1914 25,701,954 tons were milled of a value of 26s. 6d. per ton, as against 27s. 9d. in 1913, at a cost of 17s. 1d. per ton against 17s. 11d. in 1913.

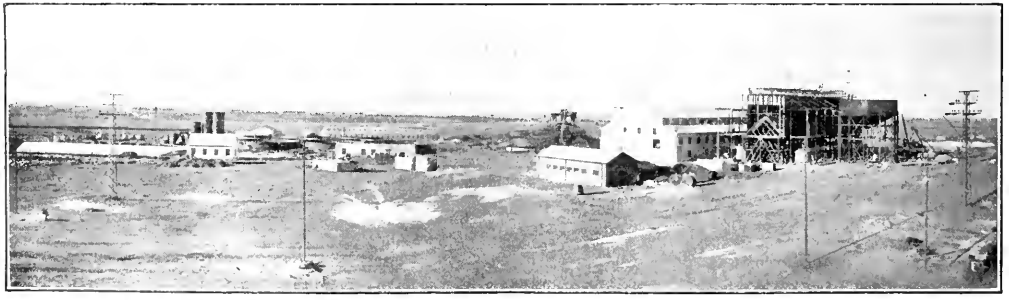
WAR'S EFFECT ON WORKING COST

Working cost has received a setback because of the increased cost of materials, for which the war is responsible. This is estimated at about 5d. per ton. The chief economy in working cost seems to have been due to a reduced white-labor cost per ton milled, and this has been partly on account of increased efficiency and partly because of reduced rates of wages, the average wage-rate paid having been considerably lowered in the last year. The mines will, however, have to pay a special war contribution of £150,000 this year besides the usual profits tax of 10% nominal. Despite this fact, the shares of the newer mines have lately shown large advances because of favorable developments and increased profits.

The native labor outlook has been somewhat more favorable recently, though in some parts of the country, because of the very wet season, malaria has caused great mortality. In the northern Transvaal whole kraals (villages) have been wiped out, and in one district alone from 10,000 to 11,000 natives and many whites have died. The death rate has been reduced from 22.1 to 14.9 per thousand and the accident death rate from 4.5 to 3.5 per thousand. There is talk of opening some of the idle mines to take care of the increased labor supply, but some mines are still short-handed, so that, especially in view of the European situation, the rumors are probably premature. Nevertheless, there is a boom in the stocks of some of these quiescent companies.

The mining industry in other parts of the world does not realize how serious a matter the compensation of phthisis victims has become to the mining houses. No less than £608,000, or 5.6d. per ton milled, was awarded last year. So far there seems to be no great diminution in the number of applicants for relief, and this year the government has issued a mining regulation forbidding miners going back to blast the round after firing the cut. No doubt this was a very great factor in producing the disease, as it is difficult even with the use of water blasts to reduce the fine dust to 10 mg. per liter of air under half an hour.

The native and white miners in development work still produce quite a lot of dust in drilling, though there is a really good water supply at all faces in most of the mines. This is done despite the best efforts of the mine officials and inspectors. I do not think, however, that even this dust is sufficient to cause any great amount of disease, as I know miners who have always fired their cut and round together, thus avoiding the smoke and dust of explosion; and these same miners have been exposed to much dust during drilling, especially in the blast. These men are still alive and working after 10 to 15 years' employment here. There is no doubt that the conditions generally are much better than they were. Nearly all broken rock is well wet down before being shoveled, and tests show that the amount of dust in the mine air is much reduced. There are, of course, portions of nearly all mines where even with fans installed ventilation conditions are bad. This is a matter which it is hard to remedy entirely, and it seems that despite all that has been done men are still contracting phthisis.



PLANT OF THE GOVERNMENT GOLD MINING AREAS (MODDERFONTEIN) CONSOLIDATED, LTD., ON THE WITWATERSRAND

The question of the sale of illicit liquor—mostly cheap wine-brandies from the Cape Province—to the native mine laborers has been attracting a great deal of attention. The well-known mine magnate R. W. Schumacher is leading a campaign in favor of prohibition and the stoppage of all imports of liquor. It seems, however, that experience in America proves that so long as the great bulk of the white population desires liquor, prohibition legislation carries great evils in its train. An article from some impartial authority in the *Journal* on the real

conditions in the prohibition states, especially the states where a mining population prevails, would be welcomed by mining engineers in other parts of the world.

Types of Drills Favored

The use of hammer drills for development work, particularly those of the Leyner type, is gaining ground on the Rand, as where attention is paid to the care of the steel it is found that the great progress made more than pays for the greater maintenance costs. Piston drills will, however, do most of this work and also most of the stoping, but unless improvements are made they may be supplanted by hammer drills which have been developed to suit conditions obtaining here.

The conditions at several of the older mines of the Central Rand are causing anxiety among miners and mine officials. Serious shocks owing to heavy falls of ground are constantly being felt in the town itself, and several of the mines have had their work nearly stopped. Despite much packing and some sand filling, it can be understood that the almost entire removal of two strata dipping 60° to 40° about 80 ft. from each other and about 5 to 10 ft. thick must cause extensive movements through unbearable stresses on shaft pillars and other supports. Some peculiar phenomena have already occured in the lifting of a solid quartzite footwall in a very narrow excavation. Fortunately great loss of life has so far been avoided, and a government commission is to be appointed to remove such danger.

Changes in Ore Value

It is now generally admitted that on the whole there is a marked falling off in the value of the reefs in depths. Nevertheless, some very encouraging instances of excellent developments at between 3000 and 4000 ft. are in evidence. For the last quarter, mainly in drives below 4000 ft. in the Village Deep, 1804 ft. driven on main reef leader assayed 21.6 dwt. over 20 in., while the Coulin Reef, which in the upper part of the mine was mostly unpayable, assayed 9.1 dwt. over 21 in.

On the East Rand at between 3000 and 4000 ft. depth wherever the orebody is well developed—where the pebble bed contains large pebbles—the gold content is high, and any unpayable ground is generally due to the irregular nature of the reef, which sometimes peters out altogether—a condition which of course has nothing to do with depth. In the deeper levels of the Crown mines, the reefs have been poorer. The lower levels of the Witwatersrand Deep have entered poor ore, while those of the neighboring Knight Central are miserably poor. On the other hand, the values met with recently in the Simmer Deep show some improvement and the drives from the deeper levels of the Angelo Deep—which has always been most disappointing in values—at a depth of about 4000 ft. have recently intersected the reef beyond a fault, over 1000 ft. being disclosed by three crosscuts. These assay: (1) Main Reef, 37 in., 19.1 dwt. and M.R.L., 23 in., 18.6 dwt.; (2) M.R., 68 in., 7.4 dwt.; (3) M.R., 35 in., 12.1 dwt.; M.R.L., 48 in., 6 dwt. This seems to be a continuation of a run of rich ore worked by the Witwatersrand Deep.

The main interest for the future of the Rand lies in the Far East Rand Basin. Here very necessary development, if the Rand is to maintain its output, has been hung up, firstly, owing to the unfortunate strikes of January and July, 1914, which undoubtedly prevented a move being made to secure fresh capital; and, secondly, because of the contention of the mining houses that the terms asked by the Government for the lease of several valuable areas belonging to them were excessive. These terms amount to the Government requiring from 30 to 50% of the profits; and in view of the depth at which most of the available reef lies the proportions of unpayable ground and other risks of mining, involving the outlay of at least £1,000,000, the investors contend that the tax on profits should not be more than the usual 10%. I think, however, that a tax of about 25% will be found reasonable by both sides. The area of ground allowed for a mining area will probably be about 2000 claims, of which half may be considered to be unpayable ground and the remainder to contain about 20,000 mill-tons per claim of a value of from 25s. to 30s. per ton.

Mills Starting Crushing

During the year the state mines began crushing. The mill has been supplied from stoped ore, low-grade development, dump rock and current development, so that the real grade of the mine has not been reached. It is expected that this will lie between 26s. and 28s. per ton. The reef attains a width of 10 ft. in places and the mine developments already guarantee at least 50% of the 2600 claims being payable.

The Modder Reef mine also started crushing, its mill being designed to deal with about 100,000 tons per year. The mine is estimated to contain about 1,000,000 tons of ore. The ore developed represents six years' supply, being 2,150,000 tons, valued at 8 dwt. over 69 in. Stoping on this mine is being done with Leyner drills.

The Brakpan mine has not yet developed another orebody like the one which produced phenomenal profits in its early history. Ore reserves are 2,490,000 tons, valued at 6.73 dwt. over 62 in. The unpayable reef amounts to 5,211,000, or about 50% of the tonnage developed to date. Leyner rock drills are used for development and some stoping is being done with hammer drills. Costs are 18s. 6d. per ton. Underground mechanical haulage is largely employed.

Springs mines has incurred a cash expenditure of £808,000 in sinking two shafts to 3000 ft., and in opening the mine 54½% of the footage sampled on the reef has averaged 22.7 dwt. over 26.7 in. Already 533,000 tons, valued at 10.3 dwt. over 52 in., has been developed.

The New Modderfontein mine is to increase its crushing capacity to 1,000,000 tons per year and the new circular shaft is being equipped for production. The Modder B, Van Ryn Deep and Geduld mines have all increased their production and their profits. The New Kleinfontein will shortly reopen the Benoni and Apex mines.

Condition of Milling Plants

All this portion of the field is thus in a flourishing condition. The East Rand Proprietary has again been unable to develop as much ore as has been milled. The tonnage milled was 1,499,089, of a value of £1 7s. 1d. per ton, at a cost of 19s. 4d. per ton, while 1,070,970 payable tons was developed. Payable ore reserves are 5,100,000 tons, averaging 6.6 dwt. over 55 in. Unpayable reef now amounts to 8,928,700 tons, most of which has been encountered on the lower levels of the mine. The

Simmer Deep mine, working down to a depth between 3000 and 5000 ft., despite shortage of laborers and the effect of strikes, made a working profit of £39,000 for 1914. The payment of interest and redemption of debentures—which amount to £835,000—and the profits tax more than absorbed this amount. The mine has worked on a narrow margin of profit, working costs being 15s. 5d. per ton and the value of ore 16s. 7d. recovered. Ore reserves amount to 1,129,000 tons at 4.3 dwt. Better values have recently been encountered, leading to a hope for more profitable returns; 307 claims have been developed, 31 of which contained dikes and 54% of the remainder payable ore; 985 claims remain to be explored.

Yield and Data

The City Deep since starting has produced at the rate of 35s. 11d. per ton milled; costs have been 23s. 9d., with a nominal profit of £1,097,783. Shareholders have, however, received only £600,000 in dividends. The chief reasons for this poor showing have been mentioned before. Ore reserves amount to 2,500,000 tons, valued at 9.7 dwt. per ton.

The Crown mines' yield fell off greatly during 1914, and development at the South Reef showed 36% to be payable. Ore reserves are now estimated at 10,000,000 tons, which are valued at 6 dwt. over 66 in., or a recovery value of 25s. 1d., the original estimate of 35,000,000 tons being 28s. 6d. The mine during the last few years has, however, been crushing ore returning 29s. 10d., so that a fall in grade is now inevitable, apart from poorer development. Costs have been reduced to 15s. 6d., with a monthly tonnage milled of 192,000, whereas the mill could deal with 40,000 tons more, were labor available.

The Consolidated Langlaagte has reduced costs to between 13s. and 24s., and is making large profits. In the Far West the Randfontein Central mines, which work 7½ miles of outcrop, have an ore reserve of 6,826,000 tons valued at 6.6 dwt. During the year, owing to shortness of labor, strikes and other causes, only 883 stamps operated, out of 1000. These crushed 2,493,984 tons, returning 23s. 1.1d. with costs of 16s. 7.4d. and a working profit of £813,774, or 6s. 6.3d. per ton. Of this sum, however, £303,757 was required for capital cost, £258,000 for debentures and redemption, £62,404 for miners' phthisis and £52,877 for profits tax, leaving a real profit of only £157,301.

Nevada Consolidated Second Quarterly Report, 1915

The Nevada Consolidated Copper Co. reports for the second quarter of 1915 a production of 15,106,920 lb., made up as follows: April, 4,710,684 lb.; May, 5,271,756 lb.; June, 5,124,480 lb., an average monthly production of 5,035,640 lb. During the quarter 849,155 dry tons of Nevada Consolidated ore, averaging 1.40 per cent. copper, was milled, as compared with 564,813 dry tons, averaging 1.49 per cent. for the previous quarter. The entire tonnage milled was supplied from the openpits. In addition, 17,541 dry tons of Giroux Consolidated Mining Co. ore was milled during the quarter.

The cost of copper produced, including Steptoe plant depreciation and all charges except ore extinguishment and after crediting all miscellaneous earnings, was 8.93c per lb., as compared with 8.97c. for the previous quarter. The earnings for the quarter are computed on the basis of 17.006c. per lb., and all unsold copper on hand and in transit is inventoried at 13½c. There was a surplus for the quarter of $614,297, after paying the 37½c. per share dividend of June 30. There was set aside $145,764 for depreciation and $84,545 for ore extinguishment, leaving a net credit to earned surplus for the quarter of $383,988. The overburden stripped during the quarter amounted to 754,649 cu.yd.

Zinc Smelting in Great Britain

The following paragraphs are taken from the address of the chairman of the Central Zinc Co. at the recent annual meeting of its stockholders. They are of peculiar interest, disclosing as they do the operations at the most modern zinc smeltery of Great Britain during a year of war, the proprietary company being intimately associated with one of the great zinc-producing companies of Australia. The chairman said, in part:

Within a week of the last annual meeting the great war which still rages began, and in consequence we have had a year full of anxieties and difficulties. I am glad, however, that in spite of them my anticipations of better results for our company have been verified, and that our profit for the past financial year, amounting to £10,413, is the best we have yet made, exceeding by £1267 that of 1912-13. The chief reasons for this improvement are that, owing to our having chosen the right moment to make favorable coal contracts, we have had cheaper coal than in the previous year, and owing to favorable freight contracts made before the war began, have had the advantage of lower ocean freight. We have also had the benefit of higher prices for our product and of the purchase on very favorable terms of a large parcel of calamine, while our technical work and recoveries have shown further improvement. On the other hand, we have had acute labor difficulties to contend with, interruptions of work and increased cost of many of our essential materials.

LABOR SUPPLY SHORT

For the first four months of our financial year—that is to say, for April, May, June and July of last year—our working was on normal lines on a six-distiller basis. On the outbreak of the war, our position at once became extremely difficult on account of the considerable number of reservists employed by us, who were immediately recalled to the colors, and also owing to the quick and patriotic response which many of our men who are not reservists made to the call for recruits. Of the trained hands in our distillery a good many were of German and Austrian nationality, and in view of the national importance of our continuing our output of spelter without interruption we decided, in consultation with the authorities, to retain those men under special conditions, by which they were virtually interned at our works, and so enabled us to assist in the production of a much-needed metal instead of being a charge on the country. By these means, except for about five weeks when one of our furnaces was shut down for repairs, we were able to keep six distillers in operation until Nov. 16, when one had again to be shut down owing to acute general labor shortage, and we continued with five distillers until Dec. 16, when the bombardment of Hartlepool and Seaton Carew by the German cruisers took place. This outrage naturally roused the bitterest feelings of the inhabitants against all enemy aliens in the district, and in deference to these feelings we decided, in spite of the inevitable dislocation of our work which would follow, to apply for the removal and internment of these German and Austrian workers. The result of this was that from Dec. 19 until the close of our financial year, on Mar. 31, our operations were greatly restricted, and were with difficulty maintained even on a three-furnace basis.

RUSSIAN AND BELGIAN WORKERS

We lost no time and spared no effort in endeavoring to recruit Russian and Belgian labor to replace that which we had lost, and although for some time we were not very successful either in the quantity or in the quality of the men we got, we have. I am glad to say, since the financial year closed obtained a much more satisfactory supply of Belgian workmen, many of whom are trained distillery hands formerly employed in Belgian zinc works, with the result that we have now six distillers again in operation, and hope to start a

seventh very soon, while an eighth is being completed as rapidly as possible and will, we hope, be available about the end of the year. A further adverse effect of the outbreak of war was that our very favorable contract for the sale of our silver-lead residues to a German firm came to an end, and in place of it we have had to make another contract on less favorable terms with London buyers, who, moreover, owing to the congestion of their works, are only able to take deliveries very intermittently. Our supply of foreign clays for our retorts was also cut off by the war, and although we at once took steps to obtain the best domestic clays available, these have proved both more costly and less durable than those we had before, so that the cost of our retorts has risen considerably, and their shorter life has made high metal recoveries more difficult. Against these many and grave difficulties caused by the war, the only way in which we have received any compensating benefit has been by the increased value of spelter, our average net sale price of zinc for the financial year having been £27 0s. 8d., against £22 5s. 6d. in the previous year and £26 10s. 11d. in 1912-13. Considering how much our work in the past has been interrupted, it is surprising that our tonnage of ore treated and of spelter and residue concentrates produced should show so small a falling off, the ore tonnage being 825 tons less than in the previous year and the spelter production less by only 269 tons. In the production of blue powder there was an increase of 63 tons, owing to the production of this material in the furnaces having been encouraged in consequence of a rise in its value; and from our distillery residues we produced 3350 tons of silver-lead concentrates, against 3321 tons in the previous year.

WHY ENGLAND IS BACKWARD IN ZINC SMELTING

I have often heard wonder expressed that, in spite of the fact that some of the most important sources of supply of zinc ores are situated within the British Empire, especially at Broken Hill, the industry of spelter making should be so much in German hands, and the Broken Hill mines so dependent on German buyers for the disposal of their material. We, at any rate, have done something to provide a British outlet, and the Broken Hill Proprietary Co. has also established zinc works on a moderate scale in Australia; but the fact is that hitherto British spelter works have not been successful enough to attract large capital to the industry, owing mainly to the difficulty, both in this country and in Australia, of obtaining an adequate supply of skilled labor. We have ourselves experienced our full share of this difficulty, and have found that English workmen are most reluctant to undertake work of this kind, to which they are unaccustomed and which, although it is not dangerous to health, is certainly laborious. In this respect England is at a disadvantage as compared with those continental countries in which spelter making has become almost an hereditary industry with certain classes of workmen, and which are also better situated in respect of the clays which are necessary for the retorts used in zinc distilling, but even on the Continent, so far as I know, the average return on the large capital involved in zinc works is very moderate, and in some cases very heavy losses have been incurred.

I am entirely in favor of England, if possible, making herself more independent of foreign countries in the manufacture of this metal, and the Government, I think, should assist by a duty on foreign spelter, or, failing that, a bounty on domestic spelter, but any attempt suddenly and hurriedly to build enormous new works here, such as I sometimes see advocated by those who know little of the difficulties would, I am sure, lead to disappointing results, and whatever is done in the direction of increasing the domestic output of zinc will have to be done cautiously and gradually. It must be remembered that the spelter works on the Continent, built at the cost of many millions, were at the outbreak of war quite sufficient to produce all the zinc that Europe in normal times can absorb, and if new works on a great scale are now to be built in England the result, unless some of the continental works should be destroyed before the war ends, may be an over-production of the metal and a fall in price, a state of affairs which, although it might be acceptable to galvanizers and brassfounders, would be calamitous both to the owners of spelter works and to the mines which produce zinc ores. Of such ores there is a great abundance in the world, and the limiting factor in the supply of metallic zinc does not lie in any scarcity of mineral deposits, but mainly in the high cost of works to convert these ores into metal and the difficulty of obtaining an adequate supply of skilled labor to make them successful. In our own case our policy is gradually to extend our works until they reach a capacity of 20,000 tons to 25,000 tons a year, which will mean an addition of from six to eight distilling furnaces to the seven we now have and the eighth which is in process of completion. We are also considering schemes for making refined zinc, of which there is considerable scarcity, and for establishing rolling mills for the manufacture of zinc sheets, but we realize that such extensions will require both time and money, and that perhaps they could be better undertaken by our parent company, the Sulphide Corporation, which has larger resources than we have, and which is directly interested in increasing by all possible means the outlet and market for its ores.

The foregoing is rather strange reading in view of the recent prices for spelter in England. However, it is to be remarked that the fiscal year of this company terminated on March 31 and the extravagances in spelter did not begin until April. Yet there was previously a great dearth of spelter in Great Britain. Comparisons may well be made between the statements of the chairman of this company—the Earl of Kintore—and the recent editorials in the *Journal* on zinc smelting in Great Britain and on allied subjects.

State Valuation of Michigan's Iron Mines

SPECIAL CORRESPONDENCE

Valuations have been placed on all Michigan iron mines for 1915, the total now being $89,757,607, which is $1,814,508 less than last year. Valuations by counties are: Gogebic, $34,572,115; Marquette, $28,616,453; Iron, $20,856,919; Dickinson, $5,906,443. The reduction is because several mines have been greatly depleted and because of lower prices for iron ore during last few years. Assessment figures are based on average price for the five years preceding assessment. Republic mine, at Republic, which was valued at $1,110,299 last year is now valued at $520,000, as mine and timber holdings were sold during the year for $600,000. Pewabic at Iron Mountain was reduced from $478,000 to $102,000. Newport still has highest valuation, being placed at $8,074,000.

M. and M. Society To Urge Mining Law Revision

The following announcement from the latest Bulletin of the Mining and Metallurgical Society of America sets forth the progress made by that organization in its effort to secure revision of the present antiquated United States mining law.

On Feb. 19, 1915, H. V. Winchell, chairman of the committee on mining law, presented to the council of the Mining and Metallurgical Society a progress report which was printed in its February Bulletin. In accordance with the suggestion of the committee, and the action of the council at that time, the executive committee of the council entered into correspondence with Washington officials and others interested in securing necessary changes in the mining laws of the United States, with the object of arranging for a meeting of the Mining and Metallurgical Society in Washington during the coming fall or winter, at which meeting, not only the Mining and Metallurgical Society, but all other organizations interested in the changes proposed might present such facts and arguments to the members of Congress and other interested officials as would bring about some positive action by the Government during the next session of Congress.

The result of this correspondence has been most encouraging. All of the officials approached have not only given their hearty approval of the program, but have offered to cooperate to the fullest extent.

After considerable discussion it has been decided to hold the Washington meeting on Thursday, Dec. 16, 1915. By this time the various congressional committees will have been appointed and will be ready to consider proposed legislation. An earlier date seemed inadvisable.

The following organizations have been asked to send representatives to the meeting: The American Institute of Mining Engineers, American Mining Congress, Lake Superior Mining Institute, Colorado Scientific Society, Colorado Metal Mining Association, California Metal Producers' Association, Montana Society of Engineers, Idaho Mining Association, Spokane Mining Men's Club and the Spokane Technical Association. In addition to the foregoing, various chambers of commerce and individuals interested will be invited to attend by representative or in person.

It is the desire of the council to make this meeting thoroughly representative, and members are urged to suggest the names of additional organizations or individuals, not connected with any of the foregoing organizations, who may be interested and who should be invited to attend.

Spelter Production for the First Half of 1915

The production of spelter for the first six months of 1915 has been canvassed by C. E. Siebenthal, of the Geological Survey, with the following results.

The output of spelter was 207,634 short tons made from domestic ores and 8898 tons from foreign ores, a total of 216,532 tons, as compared with 177,991 tons for the preceding six months, and with 175,058 tons for the first six months of 1914. In addition there was produced by distillation from drosses and skimmings 13,546 tons of secondary spelter, as compared with 10,213 tons, half of the 1914 output of distilled secondary spelter. No statistics were obtained of the spelter produced by remelting skimmings, drosses, etc., but it was probably not less than 12,000 tons. The total output of spelter from both ore and skimmings was therefore about 242,000 tons, or at the rate of 484,000 tons per year. The whole number of retorts in operation in June was about 127,000, but many of these retorts had been but recently put in operation. Additional retorts to the number of over 32,000 have since been completed, are under construction, or are planned.

The apparent domestic consumption for the six-month period was 160,906 tons, as against 149,762 tons in the preceding six months, and 149,306 tons in the first six months of 1914. The spelter stock on hand at smelteries were 5884 tons, an average of about 150 tons each for the plants reporting.

Utah Copper Co.'s Quarterly Report

The Utah Copper Co., Bingham Cañon, Utah, reports for the second quarter of 1915 a gross production of total copper contained in concentrates as follows: April, 12,015,148 lb.; May, 14,053,765 lb.; June, 14,330,912 lb.—a total of 40,399,825 as compared with 26,445,995 lb. in the first quarter of 1915. There was treated at both of the company's plants a total of 2,215,159 tons of ore, compared with 1,396,341 tons for the previous quarter. The tonnage handled during the quarter was the largest ever treated in the history of the property, the previous high record having been for the fourth quarter of 1913, when a total of 2,113,080 tons was milled. The average grade of the ore milled was 1.42% Cu as compared with 1.44% Cu for the first quarter of the year, and the average extraction was 64.85%. The extraction was low, partly because the ore at times contained considerable copper in the form of carbonate, but principally on account of the very large tonnage of ore treated. The average cost per pound of net copper produced during the quarter, after allowing the smelter's deduction and without crediting miscellaneous income, was 7.49c., as compared with 8.19c. for the first quarter of 1915. If the net miscellaneous earnings in Utah, including those from the Bingham & Garfield Ry., were applied as a reduction of costs, the net cost per pound for the quarter would be 6.57c. The financial results of the company's operations for the quarter were: Net profits for milling operations, $3,680,249; other income, rents, etc., in Utah, $36,862; income from Nevada Consolidated Copper dividend, $375,187; Bingham & Garfield Ry. dividend, $320,000; total net profit, $4,412,299, from which a dividend of $1,624,490 was paid, leaving a net surplus for the quarter of $2,787,809. The dividend declared June 30 was at the rate of $1 per quarter instead of the 75c. paid previously.

Earnings for the quarter are computed on the basis of 15.98c. per lb. for copper as compared with 14.93c. for the previous quarter. All unsold copper on hand and in transit is carried in the inventory at 13.50c. per lb. During the quarter there was removed a total of 1,548,132 cu.yd. of capping as compared with 1,143,596 cu.yd. for the first quarter of 1915; an average of 16,798 tons of ore per day was moved over the Bingham & Garfield Ry. from the mines to the mill; an average of 2921 tons per day of other freight was transported over the line.

United States Magnesite Output Increased in 1914

The crude magnesite produced and sold or treated in the United States in 1914 amounted to 11,393 tons, as compared with 9632 tons in 1913, according to the Geological Survey figures. Magnesite is used for making soda-water gas, refractory brick, furnace hearths, crucibles, for digesting and whitening wood-pulp paper, in cement making and for various other purposes. The production of the United States is still derived exclusively from California.

The consumption of magnesite in the United States in 1914 was about 122,000 tons of calcined, and 13,000 tons of crude material imported, and the raw production as reported above. The imports were thus equal to 96% of the total consumption, 93% coming from Austria-Hungary, the remainder from Greece.

Gold Production in Georgia in 1914 was 787.06 fine ounces, valued at $16,270. The production in 1913 was valued at $15,108. The yield of placer gold was 534.20 fine ounces in 1914, and the output from quartz or deep mines was 252.86 fine ounces. The output came from 26 placers and 11 deep mines. A total of 1750 short tons of siliceous gold ores, with an average gold and silver recovery of $3 a ton, was treated in Georgia in 1914. The production of gold was contributed by mines in 14 counties, of which Lumpkin County had the largest number of operators and the greatest output.

Editorials

The Prospect for Copper

The hopes for a rally in copper that were recently entertained failed to be realized and the price has declined further. It appears that the buying for ammunition in June, and earlier, was much in excess of the immediate requirement, and although further contracts have probably to be made the buyers are more cautious, slower to act, than they were. In the meanwhile production has increased to about the limit of present refinery capacity. Domestic consumption has failed to increase materially. Although the producers have already contracted to deliver a good deal of the copper that they expect to produce for a long while ahead, even in 1916, there remains a large supply of current production to be sold, and the excess of supply over demand is having the natural effect.

Yet, the position of copper is fundamentally sound. The stocks in the hands of refiners are not increasing to any disconcerting extent. There are not believed to be any speculative accounts in the metal that have to be liquidated. A big operation of that sort that was conducted on the sharp rise in copper, early in the spring, is supposed to have been concluded before copper reached its highest point. There has been no gossip of speculators buying copper at the top and meeting with the fate of some of the adventurers in spelter and lead. Nor has there been any considerable volume of speculation in the shares of the copper stocks. On the contrary, they have been conspicuous by the neglect of them and it is well known that the standard issues have hardly been selling for prices representing their liquidating value on an average of 14½ @ 15c. for copper. Anaconda, for example, has at no time in 1915 sold so high as it did in 1914, before the war. There have therefore been no great bubbles blown in copper that must inevitably explode.

Trying to look into the future certain factors seem reasonably clear. The production of Chuquicamata, Katanga and Inspiration is going to increase. If it appears, however, that the weight of their production added to what is being piled on from other quarters is excessive, the large producers will probably curtail. They learned in 1914 how easy it is to do that, and there is no longer the tendency that there used to be to try to hog the market. On the contrary, there is a better recognition of the wisdom of operating for the common welfare and therefore there is now a spirit of friendliness among competitors.

So long as the war lasts there is going to be a very large quantity of copper used for ammunition, but of course such a consumption is not going to maintain the copper industry of the world. The great uncertain factor at the moment is the consumption for peaceful purposes, which is still below normal, especially in the United States. When is it going to revive? This country is growing rich in money out of the sale of its products and its labor at high prices, and sooner or later that money must be invested in increased means for transportation, in buildings, in improvements, etc., all of which will require copper. The remarkable revival in the iron and steel industry, which can hardly be due wholly to military requirements, is conceived to foreshadow this. Yet we should not be disappointed if a great expansion in domestic peaceful industry does not happen right away. Such expansion must be based upon the financing of bonds and securities, and although we have the means to do that the uncertainty of the times breeds caution. Next there are the questions of men and of plant, both of which are now occupied to a large extent with military business. The two things—war and peace—do not economically dovetail well together. Many months ago the view was expressed in the *Journal* that it would be better for the prospects for increase in domestic business to have copper hold around 15c. than to have it raised to 20c. by military buying. We have seen strikingly how the excessive rise in spelter—far more extravagant than the rise in copper—paralyzed ordinary commercial consumption. Thus a few producers profited hugely, but to a large extent at the expense of peaceful Americans, not warring Europeans.

The only possible deduction from these forecasts is that we shall probably see copper at a lower level than it is now before the end of this year, although there will no doubt be rallies on sporadic buying movements. Yet there is nothing to be pessimistic about. Seventeen cents, or 16c., or even 15c. is a fine price for copper. If the market holds around such levels up to the termination of the war, everybody ought to be satisfied. We find among experts in the trade a unanimous opinion that upon termination of the war there will be a great demand for copper.

*

Electrometallurgy of Zinc

The high price for spelter will doubtless develop an electrometallurgy of zinc, if that art is capable of development. It has in fact been an art for many years, having been practiced successfully at the works of Brunner, Mond & Co. at Winnington, England, where spelter guaranteed 99.95% Zn is produced by the Hoepfner process, a metal that is equal to Horsehead and Bertha in so far as zinc content is concerned.

The deterrents to the production of zinc by electrometallurgical methods have been three, namely: (1) Difficulty in obtaining a dense, coherent deposit of zinc on the cathodes; (2) large consumption of energy required for the decomposition of the zinc compounds available for commercial electrolysis, no matter whether it be the sulphate, the chloride or an alkaline zincate; and (3) the difficulty in dissolving a fair proportion of the zinc of the ore.

The first difficulty was mastered years ago, and recent workers in this field have had no trouble in obtaining satisfactory cathode deposits. The second difficulty is a hard hurdle to jump over. Heretofore it has limited the electrometallurgy of zinc to places where the anode reaction may be caused to serve a useful purpose, as at Winnington. The third difficulty is common to all zinc hydrometallurgical processes and refers to the formation of zinc ferrite in the roasting of the ore, zinc ferrite being

insoluble, or difficultly soluble, in most agents that are commercially available. For this reason a roasted zinc ore may give up only 60% of its zinc even to fairly strong sulphuric acid.
